GOVERNMENT INFORMATION SERVICES

THE Central Office of Information was established on April 1, 1946, to take over a wide but closely specified range of duties from the Ministry of Information. Its first annual report* is of particular interest as giving the first available description of the general organisation of the Government information services and of the responsibilities and activities of the Central Office. The report emphasizes that the Central Office of Information is not a policy department, and that the responsibility for information and publicity policy in Britain always rests with the ministerial department covering the field into which the subject falls. Primarily the Office is a professional and technical service agency for nearly forty departments, being responsible for producing information or publicity material required by them, and being treated as the expert in presentation. It performs various other services which do not entail the production of material; but any general influence it exerts in the nature and efficiency of information services derives from its relative size and central function, rather than from its constitutional powers. Apart from the fact that the Central Office itself employs no staff overseas, a similar relation exists between the Central Office and the Information Departments of the Overseas Departments and of the Board of Trade.

In home affairs, material produced by the Central Office to add to public knowledge and understanding of public affairs has been largely directed towards increasing public understanding of the national economic situation. Here the Central Office is clearly fulfilling a recognized need for Government publicity. The Government has a duty to explain its policy and legislation; moreover, publicity is required for persuasive purposes in fields of safety and health and where coercive legislation is impossible. Nevertheless, it may fairly be urged that some of the Government action campaigns such as those described in this report have been weak substitutes for a courageous policy. There is a further educational function discharged by the Central Office in the way of providing technical and specialized information to assist sections of the public in their work and also in recording and reflecting significant aspects of the national life and achievement. Here it may be noted with interest that the Central Office has arranged a number of exhibits and displays for the Department of Industrial and Scientific Research, including one in connexion with the centenary of the Chemical Society. In such a matter the Central Office is in special danger of undertaking with doubtful efficiency what independent publicity experts could do better, and the Panel on Technical Information Services may well have under review some aspects of the work of the Central Office of Information.

That is, indeed, one of the main criticisms that can be made of the work of the Central Office of Information. The report could well have included much more detailed information about its own work and the specific functions which occupy its staff of 1,698 people in such varied fields as the distribution of news, the publication of books and periodicals, the production of films, and the conduct of social surveys, tourist and photographic lecture agencies, exhibitions, and Press and poster advertising, as well as the provision of what is described as reference services. The Central Office can, indeed, prevent campaigns from overlapping and can advise departments on the use of publicity methods; but, as the report demonstrates very plainly, it possesses no authority to ask the crucial question whether any particular activity is really worth while, and to counsel a department accordingly to curtail or abandon a projected programme.

---

* Annual Report of the Central Office of Information for the Year 1947–48. (Cmd. 7567.) Pp. 56. (London: H.M. Stationery Office, 1947.) 1s. net.

This, however, is the critical question. As regards the necessity and value in general of the activities outlined in the report there can be little doubt. Such work must be undertaken by the Government of a modern State which seeks to command public understanding and support for its policies; and variations in the standard of performance of particular duties by the Central Office of Information are comparatively unimportant. The wisdom or expediency of particular projects is altogether another matter, and while the report reveals that the Central Office has not the status to raise such a question, the contents of the report alone illustrate how imperatively the public interest demands that such questions should be asked and answered plainly.

Unless the work of the Central Office of Information is to be wasted in futilities, its activities must be realistic and limited to projects for which a convincing statement of their public value can be made. The Government has already instituted an inquiry into the methods and organisation of information services. There is also needed, however, a careful and unceasing scrutiny of particular projects, such as the Select Committee on Estimates is accustomed to give, and which the Select Committee on National Expenditure gave to the Wartime Social Survey in a report published in February 1942. The present report includes a brief section on the Social Survey, which, however, adds little to the account published in *Nature* last year (161, 573; 1948) beyond listing examples of the collection of statistical data on the survey of sickness and on retail trade indexes carried out for the statistical divisions of departments and also examples of special problems into which research has been conducted. The latter comprise a survey of the composition of population and types of household in connexion with post-war housing in Glasgow; an estimate of the demand for war medals and decorations; an inquiry in Willesden in relation to the development of new towns; an inquiry as to the numbers of people likely to benefit from and use hearing aids under the new health scheme; and an inquiry into the social factors involved in the employment of women. In all, surveys were made during the year for ten departments. The work of this section again demonstrates that, in the absence of an authority at a higher level, there can be no assurance that a technical agency—such as the Central Office of Information essentially is—will be wisely used, and departmental campaigns planned with proper foresight from the point of view of the expenditure of public money or the most appropriate means of achieving the objective. Below Cabinet level, there appears to be nothing apart from critical examination by the Select Committee on Estimates to prevent the continuing wastage of public money on schemes which may originate from departmental vacillation and failure to evolve policy properly co-ordinated at Cabinet level with the requirements and policies of other departments.

The weaknesses of the Central Office of Information are, by and large, not of its own making, and there is a danger that criticism of them may be directed against the Central Office rather than against the departments and ministers primarily responsible. It is not so much the quality of the work but its quantity that is in question, and whether the right objectives are being achieved. It would be disastrous if in the present economic situation there were any interruption of the means by which the public are informed of the affairs and the purpose and implications of Government policy and action. But efforts to secure necessary exhortation and publicity cannot be multiplied indefinitely as a substitute for resolute leadership and for administrative action which really grapples with difficulties. Further, such efforts must never be allowed to obscure the vital fact that only through some form of central Government information services, both directly and with the co-operation of the Press and other agencies, can public support and understanding be secured for the measures, often unpalatable, necessary for economic recovery and for social advance.

BIOCHEMISTRY OF BEHAVIOUR

Hormones and Behavior

A Survey of Interrelationships between Endocrine Secretions and Patterns of Overt Response. By Prof. Frank A. Beach. Pp. xv+368. (New York: Paul B. Hoeber, Inc.; London: Hamish Hamilton, Ltd., 1948.) 6.50 dollars.

IN this book Prof. F. A. Beach reviews the literature on the "interrelationships between endocrine secretions and patterns of overt response" in vertebrates, the purpose of the book being "not the exposition of a thesis but the supplying of a body of facts and references". These are classified under the following chapter headings: courtship and mating; reversal or bisexuality of mating behaviour; oviposition, parturition and parental behaviour; migration; generalized aggression; social dominance or submission, and territory defence; emotion; conditioning and other types of learning; general locomotor activity; homeostasis, metabolism, metamorphosis and moulting; morphologic structures employed in specific behaviour patterns; the role of nervous stimulation; developmental aspects; major sources of variability; and interpretations of hormonal effects. The bias of treatment in favour of sexual behaviour reflects, as the author correctly points out, the tendency of experimentalists to concentrate on those phenomena in which behavioural responses to hormonal stimulation are most evident and most specific.

Prof. Beach's aim is to review the results of only the more important studies, and the uneven balance of the chapters reflects his own research interests, as do the rare statements of personal opinion in certain chapters. Usually no critical evaluations are given of the reports that are summarized, and some subjects receive very little notice. For example, eight pages only are given to the literature concerning the hormonal control of metabolism and homeostasis. The discussion of aggression and social behaviour is narrow in scope, and the chapter on emotion, while revealing the paucity of information on this subject, is scarcely a good summary of the work that is available. The sections on human behaviour with which some chapters end are also very limited. Those topics (for example, bisexuality of mating behaviour; the role of nervous stimulation; interpretations of hormonal effects) to which Prof. Beach has himself contributed, are not surprisingly the more interesting and useful, and the relevant chapters lead to certain general conclusions. For example, as the author points out, no behavioural response yet investigated depends upon one and only one hormone. Again, no hormone produces one and only one effect upon an organism. Furthermore, hormonal control of a complete behaviour-pattern appears to be mediated by several intervening mechanisms rather than a single critical one, while different behaviour patterns vary in their degree of dependence upon endocrine products, and this dependence also varies from species to species for a similar behavioural reaction.

Prof. Beach's concentration on recent work, and in particular on papers published in American experimental journals, often leads him implicitly to attribute credit for observations to workers who were by no means the first to make them. More important, it often obscures the major interest of the fields to which the observations belong, by imposing too much of the particular on the general. "The first complete survey of to-day's knowledge", as its jacket describes the book, should at least attempt to present that knowledge with a sense of proportion and perspective; and it should show how later work has derived from original studies and generalizations, and how knowledge has progressed along certain definite lines. The fact that Prof. Beach's book does not do this detracts greatly from its intellectual value. In his introduction the author suggests that books develop in one of two ways. "The first type grows like a living organism, starting with a central idea and proceeding along a course of differentiation and individuation so that the final result represents a well organized whole." In contrast, the second type (in which category Prof. Beach places his book) "grows by accretion, like a pearl, or, to use a less flattering simile, like a snowball rolling downhill". If indeed there are two such ways of writing a book, it is difficult to understand why Prof. Beach chose the second, although it is easy enough to see that the faults of his book mainly derive from it. One may hope that the other way is selected for the second book he may write, and that he does not rest satisfied with the fact that his present one is a useful review and source book of references in the borderland between endocrinology and comparative psychology.

THE ART OF PHYTOTHERAPY

Le livre des plantes médicinales et vénéneuses de France

Par Dr. P. Fournier. Tome 1: Abricot à Coloquinte. (Encyclopédie biologique, Tome 25.) Pp. lxxviii + 448. (Paris: Paul Lechevalier, 1947.) 800 francs.

During the past century, the active principles of many medicinal plants have been isolated and identified. This has had the advantage of substituting substances of known composition for somewhat indefinite mixtures, with a corresponding gain in accuracy of dosage and consistency of results. It has sometimes happened that the purified substance has not replicated all the known or suspected effects of the crude drug; and this is scarcely to be wondered at, since physiologically active substances like the alkaloids tend to be produced in groups of related compounds rather than by themselves. Members of a group, although chemically similar, may have noticeably different physiological effects. For these reasons modern pharmacopœias still include numerous galenicals side by side with plant extracts, pure 'chemicals' of plant origin, and others that have originated in the laboratory.

One would have supposed that it could only be a matter of secondary importance to a practising medical man whence an effective drug came; but it seems there is a school of medical thought that sees special virtue in a vegetable drug because it is 'organised' and 'natural'. It is from such a point of view that this book is written; but, in spite of its somewhat formidable proportions, it is intended to be a popular work. The Abbé Fournier is a botanist and writes about medicinal plants for a wide public, not about *materia medica* for medical men only. He is a great admirer of the modern use of galenicals, and follows those who see in it a branch of medicine worthy of being dignified with the special name of phytotherapy. The first requisite of such a system, he says, is to know one's plants accurately. They are numerous, often difficult to distinguish and are referred to by names which make confusion easy. He deplores, above all, modern ignorance of field botany, of which, formerly, every educated person had at least a smattering. The author has therefore set himself the task of describing the medicinal plants of his country to botanical laymen, whether they be medical practitioners or men in the street. For purposes of identification he has reduced as much as possible the use of technical taxonomic terms, and has provided numerous effective line drawings. He goes so far as to say that even a middling figure is a better aid to recognition than the best description. He presumably has the untrained layman in mind, and it is interesting to see with what success he uses this dangerous tool. He does not try it too high. The plant descriptions are prefaced by a dichotomous key of orthodox pattern, headed by the remark that it is quicker in the long run to use the key than to riffle over the pages hunting for a likely picture. Quicker and surer, no doubt, though unfortunately not so amusing.

M. Fournier is a man of letters as well as science, and his descriptions are often felicitous, as when he says of aconites: "Qui a regardé d'un peu près leur fleur, n'en oublie plus l'aspect: quasi le profil d'une Minerve casquée . . . Quant aux pétales, les découvrir est toute une affaire."

As the completed work is to cover 1,500 species, it is evident that it goes far beyond the bounds of official medicine. The latitude taken allows the author to guide his readers through many entertaining by-ways of phytotherapeutic knowledge. It allows him to bring in the successful practitioner of Lyons who, having built himself a house, inscribed above the door, "Les concombres et les melons M'ont fait bâtir cette maison", and to recall the seventeenth-century executioner who, being of a tender heart, was unable to perform his duties until he had chewed a little catmint, "thanks to which, he was instantly seized with fury" and thirsted for blood.

Properties, methods of use and, where necessary as with garlic, drawbacks are also described at length. Anyone interested in the lore of medicinal plants cannot fail to derive both pleasure and profit from these pages, whether he is prepared to subscribe to their general background or prefers to leave it where it belongs.

W. O. James

'OPEN SYSTEMS' IN PHYSICS AND BIOLOGY

Étude thermodynamique des phénomènes irréversibles

Par I. Prigogine. Pp. ix+143. (Paris : Libr. Dunod ; Liège : Éditions Desoer, 1947.)

SINCE 1934, the present reviewer has advanced the conception of the organism as an 'open system'. So far, physical chemistry has been concerned almost exclusively with reactions and equilibria in closed systems, while living organisms are open systems, maintaining themselves in a continuous exchange of materials with environment. We have stressed the necessity for an extension of physical chemistry, stated kinetic principles, and demonstrated that the theory of open systems leads to the derivation of fundamental biological characteristics as well as to quantitative laws of biological phenomena[1]. It has also been emphasized that "according to definition, the second law of thermodynamics applies only to closed systems, it does not define the steady state".

Prigogine's work, devoted to the extension and generalization of thermodynamical theory, is of outstanding importance for physics as well as for biology. As the author states, "classical thermodynamics is an admirable, but *fragmentary* doctrine ; this fragmentary character results from the fact that it is applicable only to states of equilibrium in closed systems. *Therefore, it is necessary to establish a broader theory, comprising states of non-equilibrium as well as those of equilibrium.*" Starting, on one hand, from the concept of open systems, on the other, from thermodynamics of irreversible processes, founded by De Donder and the Brussels School and in his own previous work, Prigogine derives the generalized thermodynamics for the whole realm of physical chemistry, including chemical reactions, electrochemistry, polythermic systems, diffusion, thermoelectricity, etc. These considerations lead to the solution of many problems where, as in electrochemistry, osmotic pressure, thermodiffusion, Thomson and Peltier effects, etc., classical theory has proved to be insufficient. We must restrict ourselves to mentioning a few of the most important, and partly revolutionary, consequences. Irreversible processes in open systems cannot be defined by entropy but only by the approach of a minimum entropy production. Entropy may decrease in such systems ; or, in other words, such systems may spontaneously develop towards a state of greater heterogeneity and complexity. The far-reaching significance of this statement is apparent, since it was often considered an essential difference between inanimate and animate Nature that, according to the second law, physical events appear to be directed towards a levelling down of differences and states of maximum disorder, while in organic development and evolution a transition towards states of higher order and differentiation seems to occur. The principle of Le Chatelier applies not only to closed but also to open systems. The consideration of irreversible phenomena leads to the conception of a thermodynamical, as opposed to astronomical, time.

Prigogine's pioneering work is a most important contribution towards new conceptions, the bearing of which on physics as well as on biology can scarcely be estimated. Not since de Vries' and Pfeffer's work on osmosis have essential developments of physical theory been instigated by biological considerations. The new thermodynamics shows that it is necessary not only for biological theory to be based upon physics, but also that biological points of view can open new pathways in physical theory as well.

Ludwig von Bertalanffy

---

[1] v. Bertalanffy, L., *Naturwiss.*, **28** 522 (1940) ; "Theoretische Biologie", **2** (Berlin, 1942) ; further work by Burton, Spiegelman and Reiner, Dehlinger and Wertz, Prigogine and Wiame, and others.

PLASTICS ABSTRACTED

The Science of Plastics

A Comprehensive Source Book based on the Original Literature for 1942–1946. Edited by H. Mark and E. S. Proskauer, with the collaboration of P. M. Doty, V. J. Frilette and B. H. Zimm. Vol. 1. Pp. vii+632. (New York and London : Interscience Publishers, Inc., 1948.) 54*s*.

THIS book is rather unique in character and is a result of the rapid expansion of knowledge in one field of science during a period of very considerable transition (1942–46). In effect, it is a bound volume of abstracts. Since 1942 Interscience Publishers have issued a loose-leaf form of abstracts known as *Rubbers, Resins and Plastics* covering both the scientific and, to some extent, the technological aspects of the subject. These abstracts are of particular value to the worker in high polymers generally for two reasons : (*a*) they are much more extensive than those found in any issued form of chemical abstracts and include numerical results in considerable detail ; (*b*) they cover a wider field than is normally found in chemical abstracts, picking out material from journals not normally read or accessible to those interested primarily in this science of high polymers. No doubt the success of these abstracts and the difficulty of obtaining back numbers have prompted the publishers to re-issue them in a much more convenient form. Thus the abstracts have been collected into systematic groups, so that the book takes on the character of a reference or source book of knowledge on these several topics.

The properties and evaluation of plastics claim a third of the volume, and the physical chemistry of high polymers in a state of equilibrium claims another third. The mechanism of polymerization takes up a considerable fraction of the book, and there is finally a section labelled plastics engineering, an omnibus title that includes such diverse topics as plasticizers, laminates and radio-frequency heating. Author and subject indexes conclude the volume.

In view of the origin of the book, it will be seen that this volume is one for the active worker in the subject. The abstracts are concentrated digests of papers with a sufficiency of detail to make it unnecessary in many cases to look up the original literature if only the numerical results are required. The reader has naturally to use his own critical judgment of the value of the work.

The letterpress of the volume has presumably been reproduced photographically from the loose-leaf abstracts; but the reproduction is of a high standard. As the publishers rightly remark, if the abstracts had been reset in type, the price of the book would have been much higher. Such a resetting is not really necessary in a book of this kind. A further volume is promised soon, dealing with specific types of high polymers. These volumes then can take their place with the abstract service of *Rubbers, Resins and Plastics*, starting in 1947.

H. W. MELVILLE

BIRDS OF NANTUCKET

The Birds of Nantucket

By Ludlow Griscom and Edith V. Folger. (New England Bird Studies, 1.) Pp. xi+156+16 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1948.) 18*s.* net.

THE island of Nantucket is some thirty miles off the southern coast of the State of Massachusetts, and has an area of about forty-five square miles. Various small islands, such as Tuckernuck and Muskeget, to the north-west are included in the area. The indigenous fauna consists of a few small mammals and some eight birds, so far as can be estimated from old records. The flora is likewise limited, but Scotch firs have been planted and the heather brought with them has become established in places. In sheltered hollows and near the towns there are deciduous trees.

Formerly whaling and fishing vessels were based on the island. In the winter many of the fishermen shot wild fowl for the market, and from 1870 onward sportsmen came from the mainland to shoot. Before long, ducks and wading birds began to decrease seriously in numbers; but now there is little shooting—field-glasses are replacing guns. The island has to-day become a summer resort, and birds of all kinds are increasing in numbers again. In 1870 Brewster estimated that several thousands of common terns nested on the north coast of Nantucket; but four years later this colony was depleted. Plumage hunters are said to have killed 40,000 of these terns in one year. So much for human interference. But in 1890 Brewster computed that the common tern colony on Muskeget numbered 20,000 birds. A few years later these numbers had decreased, and gradually the laughing gulls breeding there increased, so that by 1936 there were 30,000 of them. Then herring gulls also commenced to breed in the same area and by 1946 numbered 2,500, with a corresponding decrease in the laughing gulls and terns.

Owing to the exposed position of Nantucket the shoals and sandbanks around the island are continually shifting, and this seriously affects the feeding grounds of the diving ducks. Little spring migration is seen on the island, though in the autumn considerable numbers of birds pass through. The authors consider that there is a large mortality among passerine birds in the autumn migration. They have observed a warbler start off from the south low over the sea, only to be overwhelmed by a large wave. Others are regularly noted on steamers as far as fifty miles out, and apparently must suffer the same fate. In the systematic list the status of each species is given in a comparative manner, definite counts are recorded where possible, and a point is made of stating what is not known about certain species.

This interesting little work is illustrated with some beautiful photographs by Allan Cruickshank.

N. B. KINNEAR

FISHES AND FISHERIES OF THE GOLD COAST

The Fishes and Fisheries of the Gold Coast

By F. R. Irvine; with Illustrations and an Account of the Fishing Industry, by A. P. Brown, and Classification and Keys for the Identification of the Fishes, by the late J. R. Norman and by E. Trewavas. (Published on behalf of the Government of the Gold Coast.) Pp. xvi+352. (London: Crown Agents for the Colonies, 1947.) 6*s.* net.

THIS valuable book is based on collections originally made by the author for teaching purposes at Achimota College, near Accra. But, as the collection grew, interest in it spread both within and without the Gold Coast, and a more ambitious collection of named duplicates was built up. Most of the identifications were made by the late Mr. J. R. Norman and Miss E. Trewavas, of the British Museum (Natural History), from specimens sent to them there. Dr. F. R. Irvine was fortunate in also enlisting the help of his colleague, Mr. A. P. Brown, art master at the College, whose excellent drawings are a valuable feature of the book. The arrangement is based on a systematic classification provided by Norman, who also prepared artificial keys to the families, genera and species. Both marine and freshwater fishes are included. The provision of vernacular names should prove of much value to future workers in the Gold Coast region.

An important section of the book is devoted to a study of the fishing industry of the Labadi district, near Accra, and this is written by Brown. It is a most valuable contribution and may well be taken as a pattern by anyone making a similar study of native fisheries elsewhere. Another small section of the book is devoted to some of the larger and more important Gold Coast crustacea, most of which are edible and therefore appear on the markets. The descriptions are accompanied by excellent drawings and should make a useful basis for further and more detailed study of these animals in that region. Brief reference is also made to cetaceans, turtles and the African manatee.

It seems a pity that the title, to most people, will not indicate the full scope of the book. Perhaps this can be corrected if another edition is called for—as it almost certainly will be when the West African Colonies become more fully opened up to commercial fishing and research, and more becomes known about the aquatic faunas of that great region.

G. A. STEVEN

Les caféiers du globe

Par Prof. Aug. Chevalier. Fascicule 3 : Systématique des caféiers et faux-caféiers, maladies et insectes nuisibles. (Encyclopédie biologique, Tome 28.) Pp. 357+17 plates. (Paris : Paul Lechevalier, 1947.) 1,000 francs.

FASCICULE 3 of Prof. Aug. Chevalier's monographic work on the genus *Coffea* and allied genera contains a detailed account of the anatomy of some of the vegetative and reproductive parts, the genetics and variations, the geographical distribution, the systematics, and the diseases and pests of the plants concerned. All these matters are dealt with very fully, and a great deal of information is brought together in one volume. In the genus *Coffea* the basic chromosome number is eleven (as it is in the greater part of the Rubiaceæ). Most wild coffees and many cultivated ones have $n = 11$, but most cultivated varieties of *C. arabica* are tetraploid; and triploid, hexaploid, and octoploid variants and hybrids have also been recorded.

The systematic section is a long one, and the treatment accorded to *Coffea* illustrates the taxonomic difficulties met with in a genus composed of wild and cultivated plants. *Coffea* is divided into four main sections; but the subsection *Mozambicoffea* does not appear to be subordinated to any one of them. Within the four sections and the subsection sixty-four species (and one doubtful one) are recognized. Some of the species, for example, *C. canephora* and *C. arabica*, have numerous varieties. Some 'races' and some hybrids are also given binomials. The 'false coffees' described or more briefly indicated in this work are species of the genera *Psilanthus, Psilanthopsis, Lachnastoma, Diplospora, Hypobathrum, Tricalysia, Belonophora, Chapelieria, Lemyrea, Fernelia, Cremaspora, Polysphæria, Plectronia* and *Randia*, together with several other genera that have in the past been associated with *Coffea*.

Insects and fungi are the worst enemies of coffee, particularly of the more valuable cultivated varieties under certain environmental conditions. The coffee rust (*Hemileia vestatrix*) is naturally dealt with at some length.

W. B. TURRILL

Biochemie der Leguminosen und Fouragepflanzen

Von N. N. Iwanoff. Pp. vii+115. (Amsterdam : Dr. W. Junk, 1947.) n.p.

IN 1938, twelve publications appeared in Russian, each containing information collected from the available literature on the biochemistry of one of the following leguminous and fodder plants : peas, beans, soya beans, lentils, clover, sweet-clover, lucerne, lupin, timothy grass, sorghum, common vetch and chick pea. The book under review, which consists mainly of tables, was compiled from the information contained in these twelve publications by the late Prof. N. N. Ivanoff of Leningrad, who unfortunately died before the printing of the book was completed. The 327 tables, with a few explanatory notes, give the chemical composition of the above-mentioned leguminous and fodder plants, each table being accompanied by the relevant reference(s). Nitrogen ('crude protein'), crude fibre, starch and/or other carbohydrates, fat and ash contents are given for all the plants mentioned, and, in addition, for most of them, figures are quoted giving the amino-acid content of the protein(s), the composition of the ash, and analytical data on the fats. Data are also included showing the influence of different growth conditions and plant varieties on the yield and chemical composition of the fodder plants. More specialized information is not contained in this book, although for clover the hydrocyanic acid, and for lupin the alkaloid content are given, and some figures are quoted for carotene and vitamin C content of peas.

The volume, published in German, is a useful collection of tabulated data, otherwise scattered in journals published in different languages; but, although printed in 1947, the book includes no published information available since about 1938. The table of contents indicates the information contained in the tables, but the numbering of the pages in the book does not correspond to that given in this table, and unfortunately the book has no index.

J. T.

The Rh Blood Groups and their Clinical Effects

By Dr. P. L. Mollison, Dr. R. E. Mourant and Dr. R. R. Race. (Medical Research Council Memorandum No. 19.) Pp. 74. (London : H.M. Stationery Office, 1948.) 1*s.* 6*d.*

A QUESTION one is frequently asked is "Where can I read about *Rh* ?" ; but up to date it was difficult to know how to advise the questioner, since he may be a medical practitioner, laboratory worker or a geneticist. The Medical Research Council memorandum fulfils, therefore, a great need. The first part deals with the *Rh* groups, and a description of the various sub-groups and the different *Rh* antibodies is given. The triple-gene theory of R. A. Fisher and the *CDE/cde* nomenclature arising therefrom are explained. This theory has been substantiated by all recent work, and a thorough knowledge of it is essential for a complete understanding of the *Rh* group. The second part details clinical considerations, the importance of *Rh* in blood transfusions, and the diagnosis and treatment of hæmolytic disease of the newly born.

The last section of the memorandum concerns itself with *Rh* testing, and several methods of typing cells and testing sera for antibodies are described. The reader intending to carry out *Rh* testing, however, should not gain a false sense of security from reading this manual, since, in order to obtain consistently accurate results, considerable experience is required ; and one would have liked to have seen expressed a more definite opinion with regard to the value of some of the techniques described and more stress laid on the necessity for controls. This memorandum is the most clear, concise and authoritative exposition of the present state of knowledge so far published, and all who are interested in this subject should read it.

Surveying

Instruments and Methods for Surveys of Limited Extent. By Assoc. Prof. Philip Kissam. Pp. xi+384. (New York and London : McGraw-Hill Book Co., Inc., 1947.) 17*s.* 6*d.*

THE author states that this little book has been written to provide a text-book for a short course in surveying for students of all branches of engineering, and that the material presented differs from that normally found in surveying text-books, in that there has been complete re-arrangement and rejection of some subjects usually covered. The scope is that of the requirement of the engineer for surveying, in connexion particularly with the construction and expansion of works, and of the employment of surveying techniques for setting out in shop-practice—

for example, aircraft assembly, or preliminary bridge-assembly.

From this aspect the fundamental principles and details of surveying, as applied to American practice and with American instruments, are carefully and thoroughly described; perhaps here and there with a touch of the obvious. The book would be suitable for use with a general survey course for mechanical, electrical, chemical and aeronautical engineers, who may have to apply elementary surveying; but it is perhaps rather narrow for a first civil engineering course. Nevertheless, the information it contains regarding the use of survey techniques in assembly shops, etc., should be of considerable interest to structural engineers. Only American instruments are illustrated, and many of those described in detail are of types now abandoned in British and West European practice. Thus the theodolite description is limited to four-screw instruments, of which very few remain in use in Great Britain, and no mention is made of modern optical types, which are of the greatest value, not only in field surveying but also for precise setting out in the shops.

The book is well presented, contains a wealth of practical detail, and excellent sketches, and at the end there are some 120 pages of tables providing all the information necessary for computation of the type of surveying described in the book. It should prove of great value to engineers whose surveying is likely to be limited to that carried out in connexion with industrial works and who wish to apply it accordingly. C. A. H.

Standard Valves

Pp. 328. (London: Standard Telephones and Cables, Ltd., 1947.) 15*s*.

THIS is a useful handbook and high-class bound catalogue of valves manufactured by Standard Telephone and Cables, Ltd. Broadcast receiver valves which are products of the firm's Brimar Valve Division are not included. Valves are classified as preferred, current, maintenance and obsolete; only the first two types are covered by the handbook. There is a section on general information, covering, among other items, definitions, recommendations on cooling of valves, valve bases and codings. The technical data sheets include dimensioned sketches, average characteristic curves and numerical operating data. The range is extensive and, in addition to conventional valves, includes cathode ray tubes, cold-cathode relays, velocity-modulated tubes and a double-disk-seal ultra-high-frequency triode. *CV* codes are given where appropriate. Additional loose data-sheets are to be issued later, but no facilities are provided for including these in the handbook.

Education for Professional Responsibility

A Report of the Proceedings of the Inter-Professions Conference on Education for Professional Responsibility held at Buck Hill Falls, Pennsylvania, April 12, 13 and 14, 1948. Pp. x+207. (Pittsburgh, Pa.: Carnegie Press, 1948.) n.p.

BECAUSE it has become increasingly clear that the major problems of professional education are common to all professions, in April 1948 a group of university teachers in faculties of divinity, medicine, law, engineering and business in America met at Buck Hill Falls, Pennsylvania, to discuss experiences derived from their different occupations.

In order to give ample scope for discussion, the conference was deliberately limited in size, and to it was invited only those with declared interest in improving professional education. Three sessions were arranged, the first dealing with the objectives of professional education, the second with the content and methods of professional instruction and the third with humanistic and social education as preparation for professional responsibility and citizenship. Each of these aspects of professional education was considered in turn by a representative of each of the faculties invited to the conference, and all speakers were asked to draw from actual experience for presentation of their views. This made the conference necessarily limited in objective, but also led to some refreshingly practical statements which should be of value to all who are concerned with the direction of higher education.

These statements have now been set down in book form and merit close study. While it is invidious to pick out particular essays, those by R. D. Collins on "Aims of Business Education", Prof. John Romano on "The Physician as a Comprehensive Human Biologist" and Prof. Elliott Dunlap Smith on "The Education of Professional Students for Citizenship" are especially noteworthy. T. H. H.

The Right Way to Keep Dogs

By R. C. G. Hancock. (Right Way Books.) Pp. 111. (London: Rolls House Publishing Co., Ltd., n.d.) 5*s*.

MAJOR R. C. G. HANCOCK, well known to a vast public as the 'radio vet.', has achieved a masterpiece of compression in this little book. Within the space of 111 pages—small pages with large type—he has covered all that the amateur needs to know about keeping a dog. Feeding, housing, training, breeding and showing are all discussed briefly, but adequately. There is an excellent chapter on disease, and the proper use of the medicine cupboard is wisely stressed. He has even found space to deal with the immense question of choosing a dog, and he has not omitted some mention of the dog in relation to the law. Inevitably the first chapter on the natural history of the dog is the least satisfactory, for that is really a little too ambitious for a book of this size. Nevertheless, Major Hancock has concentrated on the most important points, even though they gain a little in importance through isolation. An excellent book which can be thoroughly recommended.

Récits Bara

Par Jacques Faublée. (Université de Paris: Travaux et mémoires de l'Institut d'Ethnologie, Tome 48.) Pp. 537. (Paris: Institut d'Ethnologie, 1947.) 700 francs.

THESE stories were collected by the author during a period covering nearly three years and were told to him by Bara of various ages and classes. They are the traditional tales of the country and may be told by anyone; but the usual narrator is an old man who amuses his audience at the same time as he instructs them in traditional behaviour. While the stories themselves remain constant, the tunes to which they are sung vary, and since 1900 a considerable change in the accompaniments has been noted. The tales may illustrate ritual or other customs, or may be what we should call entirely mythical, though the natives themselves appear to make no distinction between them in credibility. In this volume the stories are arranged and classified, and there are two maps showing the extent of the knowledge of the Malagaches dialect and of the tales themselves.

USE OF RADIOACTIVE TRACERS IN BIOLOGICAL RESEARCH*

By Prof. F. A. PANETH, F.R.S.
Radiochemical Laboratory, University of Durham

IF a chemist is asked to report on the use of the new tracer technique in biology, it is obvious that he is expected not to discuss the scientific problems, but the laboratory technique. The direction of the whole work, from the first planning of the experiments to the final interpretation of the results, must lie in the hands of the biologist, and all that a chemist or, for that matter, a physicist or technician, can hope to contribute is advice as to the most efficient use of tools of research which may be unfamiliar to the biologist. The ideal organisation for such a task is a team of scientific workers; it will be the more efficient the better the biologists and their helpers understand each others' points of view. This survey is meant as a contribution from the side of radiochemistry to such mutual understanding.

The introduction of tracer methods into science has been likened to the invention of the microscope in the seventeenth century. One can scarcely imagine anyone writing to-day about "The Use of the Microscope in Biological Research"; but that was largely the subject of Robert Hooke's "Micrographia" and of Leeuwenhoek's rambling letters to the Royal Society. If the power of a new technique is to be demonstrated, one must try to show its applicability to various scientific problems instead of concentrating on the thorough discussion of one of them; the desultory character of such writings can scarcely be avoided and will, it is hoped, not be too much felt in this commentary on the tracer technique.

The first tracer experiment was carried out in the Vienna Radium Institute as early as 1913; it was, however, only ten years later that G. de Hevesy used a radioactive indicator in the investigation of a biological problem; he studied the distribution of lead in a plant growing in a solution containing active lead. The choice of lead was dictated by the very limited number of suitable radioactive tracers available in those days; but lead is not one of the elements the uptake of which by a plant we are particularly anxious to study, and the very fact that the experiment was nevertheless undertaken shows how clearly its author had realized the potential importance of the tracer method for biology.

Only after the discovery of artificial radioactivity in 1934, and the production from then on of active isotopes of a great number of lighter elements, could biological research make full use of the tracer technique. About the same time methods were developed also for the separation of inactive isotopes, as, for example, oxygen of atomic weight 18, or nitrogen of atomic weight 15, which can often be used as indicators in the same way as the radioactive nuclides (atomic species). The method of their detection is different, usually more difficult—as it needs often a mass spectroscopic analysis—and less sensitive. But the basic principle of 'labelling' an element by the addition of an isotope is the same, and much important tracer work in biology has been carried out with inactive isotopes by R. Schoenheimer, D. Rittenberg and others.

Radioactive tracers can be useful in three different groups of experiments. With their help we can detect: extremely small quantities of a substance; extremely small fractions of a given substance; and the exchange of molecules or atoms of identical chemical properties. In this third group of experiments inactive tracers can very often take the place of radioactive tracers; in this survey, however, we shall only occasionally refer to isotopic tracers in this wider sense of the word.

To-day the biologist is in the fortunate position of being able to choose from the large variety of radioactive tracers which are offered in Great Britain by the Atomic Energy Research Establishment, in Canada by the National Research Council, and in the United States by the Atomic Energy Commission. The accompanying table comprises the most important of these tracers.

Element	Isotope	Half-life	Element	Isotope	Half-life
1	^{3}H	31 y.	41	^{95}Nb	36 d.
6	^{11}C	20·5 m.	42	^{99}Mo	67 h.
	^{14}C	5100 y.	43	^{99}Tc	10^{6} y.
9	^{18}F	2 h.	44	^{103}Ru	42 d.
11	^{22}Na	3·0 y.		^{106}Ru	1 y.
	^{24}Na	14·8 h.	46	^{103}Pd	17 d.
14	^{31}Si	170 m.	47	^{110}Ag	225 d.
15	^{32}P	14·3 d.		^{111}Ag	7·5 d.
16	^{35}S	87·1 d.	49	^{114}In	48 d.
17	^{36}Cl	10^{6} y.	51	^{122}Sb	2·8 d.
	^{38}Cl	37 m.		^{124}Sb	60 d.
18	^{37}A	34 d.		^{125}Sb	2·7 y.
19	^{42}K	12·4 h.	52	^{129}Te	32 d.
20	^{45}Ca	180 d.	53	^{131}I	8 d.
21	^{46}Sc	85 d.	54	^{135}Xe	9·4 h.
22	^{51}Ti	72 d.	55	^{137}Cs	33 y.
24	^{51}Cr	26·5 d.	56	^{131}Ba	12 d.
25	^{54}Mn	310 d.	57	^{140}La	40 h.
26	^{55}Fe	4 y.	58	^{141}Ce	30 d.
	^{59}Fe	44 d.	59	^{143}Pr	19·3 d.
27	^{60}Co	5·3 y.	63	^{154}Eu	5–8 y.
28	^{59}Ni	15 y.	73	^{182}Ta	97 d.
29	^{64}Cu	12·8 h.	74	^{185}W	77 d.
30	^{65}Zn	250 d.	75	^{186}Re	90 h.
	^{69}Zn	13·8 h.	77	^{192}Ir	70 d.
33	^{74}As	16 d.	79	^{198}Au	2·7 d.
	^{76}As	26·8 h.		^{199}Au	3·3 d.
	^{77}As	40 h.	80	^{197}Hg	64 h.
34	^{75}Se	125 d.		^{203}Hg	51·5 d.
35	^{82}Br	34 h.	81	^{206}Tl	3·5 y.
36	^{85}Kr	4·5 h.	83	^{210}Bi	5 d.
37	^{86}Rb	19·5 d.	84	^{210}Po	140 d.
38	^{89}Sr	55 d.	85	^{211}At	7·5 h.
39	^{90}Y	65 h.	93	^{239}Np	2·3 d.
40	^{95}Zr	63 d.	94	^{238}Pu	50 y.

In judging the suitability of tracers, the biologist will have to consider above all their half-lives (shown in the table). Remembering that, after the lapse of ten half-value periods, less than 1 per mille of the active substance is left, he will try to find a tracer with a half-life comparable to the duration of the experiment planned. Next he will have to calculate the degree of dilution his tracer is likely to undergo; his scientific collaborators will then be able to tell him how much activity has to be used at the start, taking into account the character of the rays emitted. Finally, the necessary specific activity (that is to say, number of disintegrations per second per gram of substance) will have to be discussed. In general, the biologist will be in favour of the highest obtainable specific activity, as there is always the danger that the introduction of weighable quantities of a chemical may create non-physiological conditions; but he should not demand more than seems really necessary, as the insistence on high specific activity—perhaps even on a 'carrier-free' radioactive tracer—is likely to make the task of its preparation much more difficult for the nuclear physicist and the chemist. It is the latter's job to separate the tracer nuclide chemically, after it has been produced by the fission process of uranium, or by the bombardment of stable elements with neutrons or deuterons. This analytical-chemical separation can often be considerably simplified if a small amount of the stable isotope is added; such a process is, however, irreversible and results in the permanent lowering of the specific activity. If the biologist thinks he must insist on the avoidance of this dilution, he will have to tell the chemist whether any other element may be added as a carrier, and in what quantity. Any non-isotopic element can, at least in principle, be removed again, and thus the specific activity increased.

---

* Substance of two Special University Lectures delivered in the School of Pharmacy in London on January 26 and 27, 1949.

It has always to be kept in mind that a radioactive tracer introduced into a biological system may also cause some alterations owing to its rays. For this reason the necessary total activity discussed above should not be much exceeded; nor should, at least in experiments on humans, the half-life of the radio-nuclide be of a higher order than the duration of the experiment, as it is very inadvisable to introduce any permanent activity. During recent years there has been a tendency on the side of medical men to reduce more and more the limit of tolerance for radioactive rays. In plants, too, it can be surprisingly low; it has been found that as little as 10 microcuries of phosphorus-32 in 1 litre of the culture solution may impede the normal development of the roots. If there is any suspicion that the rays of the radioactive tracer might have influenced the experiment, it will be extremely useful to apply a check by means of an inactive isotopic tracer, using, for example, carbon-13 alternately with carbon-14.

Before the biological experiment can get under way, it will frequently be necessary for the chemist to introduce the radio-nuclide into a particular organic substance. Such syntheses may be difficult, not only because the quantities to be handled are very small, but also because the radioactive material is so valuable that the chemist must try to get as nearly as possible the whole of it incorporated in the desired molecule and, inside the molecule, in the right place. Elegant methods have been developed, for example, for the labelling in an organic acid of either the carbon atom in the carboxyl group or, alternatively, the carbon atom in the α-position; or again, for quantitatively converting carbon dioxide—in which form the nuclide carbon-14 is usually delivered—into organic compounds more suitable for biological experiments. It is very gratifying that the United States Atomic Energy Commission is offering some tracer elements already in compounds which the biologist can utilize more easily; for example, carbon-14 in the sodium salt of several aliphatic acids, in steroid hormones, testosterone, etc.

A further difficulty may arise from the short life of the radioelement, which may compel the chemist to give preference to a quick-working procedure even if the yield is poor. Let us assume that we have to deal with a substance of half-life one hour, and that a satisfactory organic synthesis (100 per cent yield) would take 10 hours, while a very indifferent one (10 per cent yield) can be carried out in one hour. The first method would give us less than 1 per mille of the desired product, the second 5 per cent.

In some cases no skill of the chemist will be able to label a molecule just in the place where the biologist would like it, at least not permanently. A limit may be set by the ordinary chemical mobility of the atoms; usually the chemist will be able to give a warning as to the positions where exchange reactions may take place and give spurious results. There is also the possibility that the desired molecule is so complicated that its synthesis has not yet been achieved. Some substances of great biological importance belong to this group, for example, digitalis, insulin or penicillin. Fortunately, the biologist will in certain cases be satisfied with the second-best solution, that is to say, with a molecule which is radioactively labelled but in which the exact place of the radio-nuclide is not known. By forgoing this latter condition, the biologist makes it possible for us to use a variety of biological methods for the synthesis of tracer substances. We can, for example, grow plants in an atmosphere of carbon dioxide which is enriched in carbon-14; animals can be fed on these plants, and their excretion products may be used as fertilizers. The name 'isotope farming' has quite aptly been used for this process. If we have started with young plants and animals, we can be sure that the carbon-14 will be uniformly distributed throughout their carbon content, and there is scarcely any substance in the animal or vegetable kingdom which we may not hope to obtain in this or a similar way in a radioactive form. Thus the red blood corpuscles of 'donors' have been labelled with both iron-55 and -59 by simply injecting these radio-nuclides intravenously.

After completion of the biological experiment, the chemist's services will usually be needed for the analysis of some organs. It is true that in some favourable cases the distribution of the radioactive tracer can be followed up from outside the organism by measuring its γ-rays; such experiments are quite spectacular and can be used for medical diagnoses; in most cases, however, a β-radiation has to be investigated, and that means the careful removal of tissues and often the chemical extraction of biochemical substances.

It seems appropriate to mention here a very general analytical procedure, 'analysis by isotopic dilution', although it is not strictly speaking a tracer method, since it introduces the radioactive material for analytical purposes after the experiment is completed. The method can be of great help in all such cases where a quantitative determination of a substance seems to demand its complete extraction in a pure state. These two conditions are often more or less mutually exclusive, as, for example, if one particular member of an organic homologous series is to be extracted; losses are unavoidable if satisfactory purification has to be achieved. However, if we mix with the substance in question a known quantity of an isotopic substance of measured specific radioactivity, this activity will be reduced to a degree dependent on the quantity of the original substance present, and it will then be sufficient to separate only a fraction of the mixture in a pure state in order to calculate this amount. Let us assume that g gm. of specific activity s_1 are added to the x gm. originally present, and that, after careful mixing, the specific activity has been reduced to s_2. The specific activities must be inversely proportional to the masses in which the constant amount of activity is distributed; hence $s_2 : s_1 = g : (g + x)$, or

$$x = g \, \frac{s_1 - s_2}{s_2}.$$

From this simple formula it is clear that for finding x, only s_2 has to be measured; and as this can be done in any unknown fraction of the total mixture, quantitative extraction is no longer demanded. On a limited scale, analysis by isotopic dilution was used already in 1927 by R. Ehrenberg in his 'radiometric micro-analysis' and has more recently found wide application in the hands of H. H. Ussing and others. Inactive isotopes can, of course, be used equally well as radioactive ones, and one of the most impressive applications, the determination of oxygen in organic substances, has been made with oxygen-18.

The number of biological researches in which radioactive tracers have been used to great advantage is already so vast that we cannot attempt even to enumerate all the principal subjects. Let us mention just a few outstanding ones[1]. Radioactive hydrogen (tritium) and carbon-11 and -14 have been employed in the study of photosynthesis, and radioactive sodium, potassium and chlorine in the study of the permeability of cell membranes in animals and plants; radioactive iron has been used to measure the average life-times of red blood corpuscles and to follow up their fate in stored blood. Radioactive phosphorus helped in exploring the mechanism of the fertilization of the soil and of the metabolism of teeth. One of the best studied tracers is radioiodine; it has long been known that this element is concentrated in the thyroid gland, but tracer methods helped very considerably in a deeper understanding of the building up of the two main constituents of the hormone and of the influence that the removal of the thyroid and pituitary glands has on their production. The metabolism of the bone salt has been studied with the help of radioactive calcium, strontium and plutonium. Since it has become known that beryllium can be highly toxic, the exact mapping of its distribution in the body by means of its active isotope beryllium-7 is important.

Before concluding, I should like to direct attention to a biological tracer experiment which Nature carries out constantly and on a scale infinitely greater than anything attempted by man. The most important element in organic life is carbon, and it is just this element which Nature labels by the admixture of carbon-14 wherever it occurs in biological processes. This isotope has a half-life of about 5,000 years; it can be produced in uranium piles by the impact of neutrons on a nitrogenous substance:

$$^{14}_{7}\mathrm{N} + {}^{1}_{0}n \rightarrow {}^{14}_{6}\mathrm{C} + {}^{1}_{1}\mathrm{H}.$$

The same nuclear process goes on in the highest layers of the atmosphere under the influence of the neutron-containing cosmic rays; the carbon atoms then combine with the oxygen of the atmosphere to give carbon monoxide and dioxide. As we now know that the atmosphere, contrary to earlier views, is so efficiently mixed up by winds that its composition is practically uniform throughout its height, we must expect the carbon dioxide everywhere on the earth's surface to contain the same amount of the long-lived radioelement carbon-14; measurements by W. F. Libby and A. V. Grosse—which are difficult owing to the weakness of the activity—have confirmed this.

The biological implications are obvious. Any plant, by assimilation of the atmospheric carbon dioxide, incorporates also the small percentage of carbon-14, and from there it gets into the bodies of animals and men; but its life-time is limited. In coal and oil deposits of considerable geological age, the activity must have vanished; it was thus according to expectation when it was found that methane from oil-fields is inactive, but that methane from a sewage disposal plant contains the standard amount of carbon-14. The same difference was found between alcohol from coal and alcohol from grain. Determinations of the age of bones (measured in thousands of years) seem possible in principle, but involve, among other things, assumptions about the constancy of the cosmic radiation about which we cannot be too sure. To-day, however, any carbon participating in the life-cycle is labelled; the old distinction between 'organic' and 'inorganic' chemistry, which has passed through so many phases, seems again to have acquired a new meaning.

D., "Radioactive Tracers in Biology" (New York: Academic Press, Inc., 1947); Hevesy, G., "Radioactive Indicators" (New York: Interscience Publishers, 1948); Süe, P., "Dix Ans d'Application de la Radioactivité Artificielle" (Paris: Société d'Éditions Scientifiques, 1948); Fourth and Fifth Semi-annual Report of the U.S. Atomic Energy Commission (Washington, D.C.: U.S. Government Printing Office, 1948 and 1949). The vast predominance of biological experiments in to-day's applications of the tracer technique may be contrasted with the situation twenty-two years ago; see Paneth, F. A., *Nature*, 120, 884 (1927).

METHODOLOGY OF SCIENCE IN THE SERVICE OF THE ARTS

By F. I. G. RAWLINS
National Gallery

THIS title is intended to be distributive, in that its object is to introduce an examination of the methodology of 'science in the service of the arts', rather than the methodology of science 'in the service of the arts'. The implication is that there is, in fact, an activity recognizable in the sense of the first of these phrases. We are not concerned with a discussion of this point: the existence of such laboratories as those at the British Museum, the National Gallery, the Courtauld Institute (University of London), the Fogg Museum (Harvard University), the Museum of Fine Arts, Boston, U.S.A., and the Central Laboratory of the Belgian Museums (Brussels), is enough to decide this elemental question. Further, and in so far as the present theme has much in common with the theory of knowledge, the work carried on at the Warburg Institute, London, and at the Dumbarton Oaks Research Library, Washington, D.C., is relevant. These studies are iconographical and historical in the scientific sense. They constitute an essentially methodological framework and outlook.

The position is not wholly unlike that underlying the use of statistical and analytical processes in the social sciences. Here, without a doubt, the basis must be a sound methodology coupled with an acute appraisal of what can and what cannot ethically be done. In the immediate context much the same applies; fundamental mistakes have arisen in consequence of the assumption that laboratory tools can answer questions of style and taste. Such an outlook is manifestly absurd. Not only can no reply be expected; even some harm may be done to the cause of scientific method itself. One way to reduce, and perhaps largely to eliminate, this risk is to plan laboratory work deliberately upon first principles (including a generous use of historical perspective), introducing the special cases to be dealt with as they come along. By these means, the temptation to use the natural sciences as a 'new toy' (just to see what they can do) is kept in check.

An example is the use of X-rays to help in the task of attribution of a painting. At one time this performance was quite popular, not only among experts, but even in courts of law. With little understanding of what X-radiation is, and still less of the complex nature of its transmission through a stratified manifold such as a picture, confident assertions were made that such-and-such was the work of a certain master, and that something else rather like it was the effort of a student, or even perhaps a forgery.

In a recent instance, radiography proved exceedingly powerful, first in showing that certain pictures were executed over older painted canvases, and secondly in demonstrating the existence of two systems of fissures, one due to the contraction of the original paint and ground, and another characteristic of the recently applied visual design. Such an investigation reveals no confusion of purpose; what was sought for were matters of fact. For example, was or was not the 'picture' as commonly observed contemporary with the canvas upon which it was painted? The answer was in the negative; but radiography alone offered no opinion about who painted it.

The legitimate uses and limitations of the scientific method are thus perfectly clear. It is the task of others, pressing towards the truth maybe by other paths, to attempt a solution of the problem of attribution. Their own particular methodology is partly statistical (however unconscious), in that they weigh in their minds a large number of paintings known on independent data to be by a certain person, and 'balance' them against the sample. Partly, too, the scheme is æsthetic, in that appeal is made to a trained judgment upon the presumed artist's sense of beauty, composition, and fitness.

Thus, we are gradually becoming aware of the strivings going on to produce a new æsthetics; not an activity in any way at variance with the traditional discipline, but something at once more objective and, in the psychological sense, more highly integrated.

This means a greater emphasis upon experimental methods, quantitative wherever possible, and less perhaps upon abstractions relating to the nature of the sublime. Baumgarten's introduction of the term 'æsthetics' in the middle of the eighteenth century made it obvious that its aim was the quest for beauty, whereas that of logic was the quest for truth. In any system of methodology, however, it is ultimately the resolving power of the mind, and to what limits we are prepared to press it in the search for truth, which matters.

The point at which an integrated æsthetics can become confluent with much of scientific method is that at which descriptive and classificatory principles begin to emerge. It is probably not an accident that much the same criterion applies in focusing epistemological illumination upon the special problems of the social sciences. For they, in their turn, have conditioned (or at least the raw material out of which they are fashioned has conditioned) much of our cultural heritage, which we are now beginning to use as documents for a methodology in this particular field, namely, the scientific aspects of the arts. That some success, however limited, has already attended the introduction of the *Gestalt*-concept into the teaching of design is perhaps not without significance.

Historical Development: a Study in Morphogenesis

One has only to contemplate the majesty of the Athenian acropolis as it once was to become convinced that the Greek genius for form was allied to, and to some extent inseparable from, its outstanding accomplishments in mathematics. The same coupling appeared in a much attenuated form centuries later when the Tuscan algebraist Pacioli brought Leonardo da Vinci to think about ratios, and to study abstract quantity. Pacioli was no genius; he has bequeathed some interesting thoughts in his "Divina Proportione", and he compiled what might fairly be called a standard text-book of mathematics. Nevertheless, he was a close friend of Leonardo (who designed the illustrations for his book, published in Venice in 1509), and a natural inference is that his manipulative skill—modest as indeed it was—was enough to encourage the great artist to turn towards the study of natural law. Vietá, some half a century later, in developing a true sense of algebraic form, paved the way for that liberal species of thinking which in time led up to the foundation of a deliberate subject of æsthetics. The influence of environment in all this is naturally by no means negligible. John Ruskin's essay, "The Two Boyhoods"[1], depicts the youthful Giorgione under his Italian sun, and Turner in Soho and on Wapping Old Stairs. So far as their art is concerned, the contrast is more than a particularly effective literary device; it is an example of morphogenesis in action, clear enough to satisfy any functional biologist.

One is thus constrained to seek a unifying principle, as mankind, in spite of many lamentable failures, has struggled on in purposeful effort to realize the beautiful. It is here that methodology is at some slight advantage in view of the possibility of making qualitative criteria at least semi-quantitative. Broadly, the unifying factor seems to be symmetry: it is as if our morphogenetic plan started with a triclinic crystal, and culminated in a cubic one, a continuous increase in symmetry. Just as solids exist which have no symmetry whatsoever, so are some objects utterly devoid of beauty. The interesting moment, however, is when at least one element of symmetry can be envisaged, and the human mind grasps the conceivability of advance towards the highest types of organisation. In this connexion it is tempting to ask what is the nature and position of amorphous systems in such a hierarchy. Are they for ever outside the range of æsthetic significance? Most likely in themselves they are; but not 'for ever', in consequence of their capacity, under certain extreme physical conditions, to crystallize, and so to begin the steep ascent to perfection. In Aristotelian terms, common clay is in potency to pass into entelechy as the sapphire.

Intellectually—and this is important for the formal aspect of all methodologies—the same coercive impact upon abstract problems, the solution of which is at present unknown, is necessary if thought (and mental mastery) is to crystallize out as new knowledge. It is the 'logical pressure' demanded by Milne[2] in his work upon an adequate epistemology of physics.

The metastable and labile states of matter exhibit a suggestive parallel here. The *status quo* is obstinately maintained until the system is so completely out of energy-balance with thermodynamic necessity that change of state comes about imperatively. Correspondingly, man's course has at times been set towards new æsthetic states, which are, in the event, only achieved convulsively, when the compelling effect of creative drive and social conditions together provide the minimum of 'requiredness'. Again, as in physics, a remarkable degree of 'supercooling' can be tolerated so long as disturbance, either psychological or by the infiltration of new ideas, is avoided. An example can be seen at Barnack. Here the mixture of styles, Norman and Early English in the nave of the parish church, is due to the remote location : the trend of architectural design was unknown in its entirety, and thus a hybrid resulted. Cases of this kind must be distinguished from the forced compliance with a new technique which is known to have been brought about at various places in Europe by the invasion of neighbouring tribes. Alternatively, direction from a powerful centre, as in Carolingian times, may have occurred.

The analogue of 'logical pressure' may be expected to set in sooner or later. This would be an 'æsthetic pressure', the goal of which might be the discovery of new forms of beauty, corresponding to the search for new manifestations of truth. We shall discuss in the next section what this may involve ; for the moment, our task is predominantly historical. Here we may point out that much semi-conscious thought has evidently been devoted to speculation about new types of beauty in the past. The result is seen in the transitional nature of architecture (as already described), and in the gradual evolution of ceramics. More theoretically, the perspective of Andrea Pozzo, who was born in the same year as Newton, demonstrates morphoplastically how the Italian tradition gave place to the Baroque as the scientific activity of the Renaissance provided facts upon which to rear the edifice of deliberate three-dimensional 'effects', superposed upon a standard two-dimensional continuum.

Here, the influence of technique becomes noticeable, in its effect upon æsthetic advance. Broadly, the power of the craftsman over his materials has increased with the centuries. At the same time, new substances (for example, coal-tar colorants and thermoplastic polymers) have been placed in his hands by the labours of the chemists. Thus the possibility, though not necessarily the actuality, of artistic expression tends to increase, and with it the need for methodological control, or at least for some intellectual restraint. The position at the moment is difficult to assess, with any degree of confidence. Emphasis upon functional design (for example, factories, laboratories, and so forth) tends almost automatically to the negative virtue of the suppression of superfluous ornament. At the same time, it seems, never have we been less sure of ourselves, and therefore less willing to venture and experiment with new forms of expression. The same semi-Puritanical touch may be observed in other fields, leading to a kind of starvation of ritual and all that it implies.

A condition of neutral equilibrium seems to have set in, which may well be connected with the absence of 'glory' from the modern world, so poignantly expressed by Lord Russell in one of his Reith Lectures.

Some Axiological Considerations

The hope was once expressed by Whitehead that eventually æsthetics, ethics and even theology might be brought within the scope of symbolic logic. In so far as such an all-embracing scheme might be competent to achieve what, in principle (perhaps even in faith), Descartes and Leibniz viewed as from the summit of Mount Pizgah, we cannot but welcome it. But what exactly is it expected to do ? Any methodology applicable, through science, to the arts must clearly take account of value. It is precisely the lack of such a provision which rules out traditional Cartesianism, and indeed makes it wholly inacceptable in 'meta-situations', wherein human creativeness is most active. But modern (non-Aristotelian) logic is capable of doing exactly what is wanted, namely, to lift æsthetics (and the axiological core embedded in it) out of the bog of controversy, and to set it firmly upon a rational basis. This, however, is not likely to come about until æsthetics—ever seeking new beauty as logic ever seeks new truth—is willing to allow the 'meta' element to act inwards. Thus metaphysics becomes potent as soon as it is conceived as science acting critically towards itself. Correspondingly, therefore, we now envisage a new 'meta-æsthetics', that is, beauty criticizing itself (a thing it never does at present), and thus advancing, painfully, no doubt, along the way of sorrows, to the status of a true *scientia*.

If it be objected that there can be no possible justification for the use of yet another 'meta' subject, while the proto-discipline is so backward, or at least so wayward, the answer assuredly is that mankind's deepest experience proves the opposite. The advance of meta-mathematics, meta-languages (semantics and semiotics), and, in general, metatheory during the present century, has been most remarkable. Why not then admit at once the desirability (however difficult) of a corresponding move towards the sublimation of the beautiful ?

It is important to realize the 'dimension' in which all this is already taking place. It is neither 'upwards' nor 'sideways' : it more nearly resembles the driving in of piles and concrete to support the structure of some great medieval cathedral. Knowledge and creativeness both get tired as the centuries pass. It is not to their discredit ; on the contrary, it is an index of how liberally they have spent themselves from generation to generation. But it is time to look to the foundations, and occasionally to the "rock whence we are hewn". Few people seem to care overmuch for work of this description, with little to show for it. It is like tapping and making good beneath the lowest levels of the crypt. By all means, however, let work go on above ground at the same time, in any desired direction. All branches of mathematics and natural science are reaching out both vertically and horizontally. They, when they can, are lending æsthetics a hand, by help in the conservation of her 'documents', and a care for her outward achievements.

Thus our methodology begins by sensing the depth of the axiological problem in the quest for beauty. In harmony with what is happening to the exact sciences, it urges the need for attention in the basement. When that is safely under way, maybe the youthful meta-æsthetics will take shape comparatively painlessly ; for while opportunities for self-criticism will be numerous, they can be pursued in peace.

There is another possible gain, this time from the flank. Those whose task is shielded to some degree, and whose aim it is to re-inforce structures 'without interrupting the traffic', acquire a remarkable grasp of each others' problems and difficulties. In this way it is conceivable that concord over a wide sector of human relationships will tend to advance.

If these are ends (even perhaps necessities), how are we to orientate ourselves to reach them ? Manifestly, an educational proposition is presented, not so much novel as coercive. Its essential character is preparation for a new type of spade-work. That will take time. Luckily, there are already signs that the cracks in the superstructure have been noticed. Two examples, both recent, will illustrate. First, discussions on the possible reform, in certain major respects, of the Natural Sciences Tripos at Cambridge have led to proposals for the inclusion of historical and philosophical studies in the curriculum and examinations[3]. It is too early as yet to anticipate what the result will be; the important point is that such views should have been expressed, and that with no lack of vigour and seriousness.

The second portent is the formation of a Group, affiliated to the British Society for the History of Science, to study the philosophy of the sciences in the widest possible sense, including symbolic logic and æsthetics. (The relevance of all this to Whitehead's expression of faith already mentioned will not be overlooked.) So far, the new venture promises well.

Next, in what way or ways can people, by either of these movements, be influenced to behave axiologically, that is, perform valuable service? The answer is contained implicitly in the Cambridge report. There is a need, it suggests, for a new type of administrator, with a scientific background and habit of mind. What better than that he or she should be fashioned on these generous lines? To achieve distinction at the highest level in this new field must not be easy. If arrangements are adequate, it will certainly be no 'soft option'. Probably it assumes a degree of maturity more complete than is always the case, though that is in itself no reason why as much as possible should not be done at a less specialized stage. It should, moreover, be capable of interesting students in the faculty of fine arts, and thus to sow the seed in potentially fertile soil. Æsthetics has need of a magnanimous and strong methodology to support it. No longer should be heard within it such words as "Those [are the wounds] with which I was wounded in the house of my friends"[4].

NEWS and VIEWS

Zoological Society of London:
Mr. H. G. Maurice, C.B.

Mr. Henry Gascoyen Maurice has been awarded the Gold Medal of the Zoological Society of London, in recognition of his great services to the Society. This Medal has been awarded only three times previously since its foundation in 1877. Mr. Maurice has been a member of the Council of the Zoological Society almost continuously since 1926, and was president during 1942–48; since retiring from the office of president he has continued to serve as a vice-president. He took office in the middle of the War, at a very critical time in the history of the Society, and it was largely the result of his wise conduct of its meetings that the various difficulties of those years were overcome. Mr. Maurice's long interest in natural history and Nature protection covers a wide range. He was fisheries secretary at the Ministry of Agriculture and Fisheries during 1912–38. His wide knowledge of problems connected with the fishing industry made him an ideal president of the International Council for the Exploration of the Sea, a position he occupied for eighteen years. On his retirement he was appointed 'president d'honneur', and in 1937 awarded the Gold Medal of the Johannes Schmidt Foundation for Oceanographical Research. Since October 1936, he has been secretary of the Society for the Preservation of the Fauna of the Empire, and editor of its journal; and, in addition, he has taken a very active part in all problems connected with Nature protection. He was in charge of the British delegation to the meeting at Fontainebleau in October last year, which resulted in the foundation of the International Union for the Protection of Nature; and he was elected a vice-president and member of the executive council of this Union. Some of Mr. Maurice's fascinating essays on natural history have recently been issued in book form, "Sometimes an Angler" and "The Wisdom of the Ass".

British Agricultural Advisers in North America:
Dr. W. F. Darke

The Agricultural Departments and the Commonwealth Relations Office announce that Mr. J. A. Young, assistant agricultural adviser to the High Commissioner for the United Kingdom in Ottawa, is returning to Northern Ireland in April at the end of his period of duty in Canada. His place will be taken by Dr. W. F. Darke, who will have the rank of secretary (agriculture) in the High Commissioner's office. Dr. Darke entered the University of London in 1930, taking his B.Sc.(Econ.) degree in 1933. He was awarded a research scholarship by the Agricultural Research Council and worked at Oxford and at the University of California. In 1936 he was awarded the degree of Ph.D.(Econ.) (London) and a year later that of B.Litt. by the University of Oxford for part of his work on the history of the smallholdings movement. Dr. Darke was appointed to the staff of the Ministry of Agriculture and Fisheries in May 1938 as a junior economist. He was seconded to United Nations Relief and Rehabilitation Administration in August 1944, and in 1947 took up duty with the Food and Agriculture Organisation; he returned to the Ministry of Agriculture in January last year.

Mr. M. W. Taylor

The Agricultural Departments and the Foreign Office announce that Mr. P. J. Macfarlan, assistant agricultural attaché in the British Embassy at Washington, is returning to the United Kingdom in May on the completion of his two-years appointment, and will be replaced by Mr. M. W. Taylor. Mr. Taylor went to Emmanuel College, Cambridge, and studied agriculture. During 1933–41 he was engaged in poultry farming on his own account, after which he was appointed senior biology master at Clitheroe Royal Grammar School. Later he became technical adviser and superintendent of the experimental farm for the

Poultry Association of Great Britain. Mr. Taylor was appointed to the staff of the Ministry of Agriculture and Fisheries in December 1946 as a poultry advisory officer in the National Agricultural Advisory Service.

Mr. C. S. Windebank

MR. C. S. WINDEBANK has been appointed managing director of the Esso Development Company. This Company conducts and co-ordinates research, contract and patent work for the benefit of the Esso group of petroleum companies in Europe. Mr. Windebank took first-class honours in chemical engineering at the University of London, and in 1936–37 was at the Massachusetts Institute of Technology, where he was awarded the degree of M.Sc. In 1937 he joined the technical staff of International Association (Petroleum Industry), Ltd., in London, and later, in 1940, he was released from the Army in order to undertake technical work with Esso European Laboratories on aviation fuels. On the formation of the Esso Development Company in 1947 Mr. Windebank was made manager of the Research Department.

Royal Society of Edinburgh : New Fellows

THE following were elected fellows of the Royal Society of Edinburgh at the ordinary meeting held on March 7 : Dr. Charlotte Auerbach, 9 Fountainhall Road, Edinburgh 9 ; Dr. R. S. Barclay, statistician to the West Highland Survey ; Dr. W. Black, principal scientific officer to the Scottish Society for Research in Plant Breeding ; John Cameron, sheriff of Inverness, Moray, Nairn, Ross and Cromarty ; Prof. W. H. J. Childs, Physics Department, Heriot-Watt College, Edinburgh ; Dr. Ethel D. Currie, University of Glasgow ; Dr. D. P. Cuthbertson, director of the Rowett Research Institute, Bucksburn, Aberdeen ; Dr. A. M. Gillespie, 135 Craiglea Drive, Edinburgh 10 ; Mr. D. Grant, 19 Falcon Road West, Edinburgh 10 ; Dr. F. Gross, Zoology Department, University of Edinburgh ; Mr. J. Jack, Mayfield, Monktonhall, Musselburgh, Midlothian ; Prof. R. V. Jones, Natural Philosophy Department, University of Aberdeen ; Dr. Sheina M. Marshall, principal scientific officer, Scottish Marine Biological Association Laboratory, Millport ; Mr. N. G. Matthew, 126 West Savile Terrace, Edinburgh 9 ; Dr. Christina C. Miller, Chemistry Department, University of Edinburgh ; Mr. H. C. Pawson, assistant director and senior tutor in agriculture, King's College (University of Durham), Newcastle-upon-Tyne ; Dr. I. A. Preece, 7 Blinkbonny Road, Edinburgh 4 ; Dr. Doris L. Reynolds, 7 West Mains Road, Edinburgh 9 ; Dr. H. O. W. Richardson, Natural Philosophy Department, University of Edinburgh ; Dr. H. Sington, London ; Dr. J. Smart, Zoology Department, University of Cambridge ; Dr. R. H. A. Swain, Bacteriological Department, University of Edinburgh ; Mr. G. Waterston, Harestanes, Longniddry, East Lothian ; Mr. R. G. White, director of the Animal Breeding and Research Organisation, Agricultural Research Council ; Dr. F. N. Woodward, director of the Scottish Seaweed Research Association.

Use of the Term 'Coliform'

THE term 'coliform' has for some time had an obscure meaning, and it has become increasingly clear that a definition is desirable. Those interested in medical and veterinary bacteriology have used it to embrace only the morphological characters of many species, not of *Bacterium coli* alone, but also of the dysentery bacteria, the salmonella and other Gram-negative rods similar to *Bacterium coli*. On the other hand, the term 'coliform' is restricted by many water and dairy bacteriologists to those organisms which are not only morphologically similar to *Bacterium coli* but which also resemble it in its cultural and biochemical characteristics ; some have even regarded it as being synonymous with *Bacterium coli* of fæcal origin. Because of this confusion and also because there is now a closer liaison between all those who study bacteria from whatever aspect, a committee of nine representing this variety of interests was appointed by the Society for General Microbiology and by the Society for Applied Bacteriology. This committee met on several occasions to discuss various aspects of the matter, and it is hoped that bacteriologists in general will be able to agree upon the meaning of the term 'coliform' which has been put forward.

Dr. Reginald Lovell (for the Society for General Microbiology), Royal Veterinary College, London, N.W.1, and Dr. C. B. Taylor (for the Society for Applied Bacteriology), c/o Messrs. Lever Brothers and Unilever, Ltd., Port Sunlight, Cheshire, have forwarded the following relevant portions of the committee's report : "(1) The term 'coliform' means 'like *Bacterium coli*', or 'coli-like'. (2) 'Coliform' is an adjective, and as such has no generic or ecological significance. (3) It is proposed that the term 'coliform' should refer to Gram-negative rods resembling *Bacterium coli* in morphology and staining reactions, but not necessarily in cultural and biochemical characteristics. (4) That the widest publicity should be given to this definition to prevent the term being employed to define different specific types by different workers, or to restrict the term to particular branches of bacteriology. The committee is convinced that the proposed definition is the only one satisfactory to all interests in bacteriology and is opposed to any definition based on ecology or biochemical reactions. Existing systems allow for classification of organisms grouped under the wide term now proposed."

University of Birmingham

AT the annual meeting of the Court of Governors of the University of Birmingham, the Pro-Chancellor, Mr. Sydney Vernon, announced that the progress of building at the University would be accelerated in the present year by an increase in the available supplies of material and labour. Among the first requirements to be met is the extension of the students' union. At present a part of the new engineering building is well advanced, and it is hoped that a further portion will be undertaken very shortly. The estimated cost of the much-needed halls of residence is such as to postpone indefinitely their realization. Present needs have been met to some extent by the erection of a number of prefabricated huts which are regarded as temporary, though they appear to be more durable than the old wooden Army huts erected in 1919, some of which are still in use. The doubling of the University population during the ten years following the War was regarded as being in the national interest ; but Birmingham has already more than achieved this aim, the present number of students being between 3,250 and 3,500, a figure at which the Vice-Chancellor considers it might well be stabilized.

Among experiments aimed at broadening the education of the undergraduate, mention was made of the action in the Department of Electrical Engineering, where Prof. A. Tustin has eliminated much detail from third- and fourth-year honours courses to make room for lectures and discussions on philosophy, literature, economics, and the impact of the natural sciences on society. The students are expected to write a substantial essay each session on some topic outside their professional syllabus, and a departmental library of books on non-technical subjects has been provided. The results so far appear highly satisfactory. The problem of staff salaries has been accentuated by the recommendations of the Spens Report. Whatever solution is found, the effect on university welfare will be profound. The problem is not one of standard of living but of competition for the best human material, without which the costly measures being taken to give university education to a greater proportion of the best of the youth of Great Britain will not produce the results they should.

University of Natal

The University of Natal is celebrating at Pietermaritzburg on March 15 and Durban on March 19 the granting of a charter to the University which became effective at the beginning of this year. Sir Raymond Priestley, vice-chancellor of the University of Birmingham, Lord Eustace Percy, vice-chancellor of the University of Durham, and Prof. J. Dover Wilson, formerly regius professor of rhetoric and English literature in the University of Edinburgh, are visiting South Africa for these celebrations. They are travelling under the Commonwealth University Interchange Scheme initiated by the British Council as a result of recommendations made at the Congress of Universities of the British Commonwealth last July. Under the scheme the Council will award travel grants to university teachers travelling on recognized study leave; distinguished scholars invited for short visits; and postgraduate research workers holding research grants. The grants are made on the recommendation of a committee representing the Association of Universities of the British Commonwealth, the Committee of Vice-Chancellors and Principals of the United Kingdom, and the Universities Advisory Committee of the British Council.

Exchequer Grants for Universities in Britain

Sir Stafford Cripps, Chancellor of the Exchequer, in a written answer in the House of Commons on March 1, stated: "I am providing £12,814,500 for recurrent grants to universities. This amount includes provision for the additional expenditure which universities will incur in bringing into operation the revised scales of payment for teachers in the medical and dental schools. . . . The progress of the universities' scheme for physical expansion necessitates an increase in the amount required for non-recurrent grants, and I am providing £4¾ million for this purpose as against £2,600,000 this year."

Effects of the Mild Winter

The unusually mild weather over the greater part of the winter of 1948–49 in England and Wales has not only produced many remarkably interesting phenological observations, but also substantially contradicted the various theories and averages upon which amateur and professional meteorological observers forecast a probably severe winter for this period. Indeed, one London wild-life quarterly produced in the winter of 1948–49 a paragraph: "Nature-wise observers predict an unusually severe winter". Their reasons were: "(1) There has been an unusually heavy crop of wild berries. (2) Squirrels have been noticeably active in gathering and storing nuts. (3) Flocks of wild geese from Iceland and Russia have arrived earlier than usual. (4) Wild swans are arriving in considerable flocks. . . . (5) In the Highlands the deer have left their mountain fastnesses a month earlier. . . ." In each case the oft-quoted forecast had been disproved even so recently as the mild winter of 1947–48, which followed an abundant berry crop—the result of a previously good growing season. Very large flocks of pintail and wigeon have been recorded on the Cheshire Dee despite the mild winter.

January was free from the cold and snowy conditions usually prevailing at this time of the year. On January 24 a mallard duck was reported with a nest of four eggs in a hollow tree at Worcester College, Oxford, and it had increased its clutch to seven by January 27. In North Wales the lesser celandine was in flower from January 9 at Llanarmon, as was the water-crowfoot, and by the third week dog's mercury, hazel and barren strawberry were in flower. The coltsfoot was first reported flowering in Cheshire on January 16, compared with the thirty-five years average date of March 3. Hazel catkin flowers appeared seventeen days earlier than the thirty-five years average. The chiffchaff has been reported wintering in southern England. In Shropshire the chaffinch was first heard in song on January 31 compared with February 6 in 1948, February 5 in 1944, and February 7 in 1943. The Merseyside Naturalists' Association recorded forty species of plant in flower by March 1, 1949, compared with April 1, 1948.

The Eyasi Skull

The June 1946 issue of the *Journal of the East Africa Natural History Society* contains two articles, one by Dr. L. S. B. Leakey entitled "Report on a visit to the site of the Eyasi skull found by Kohl-Larsen", and the other by W. H. Reeve on "A geological report on the site of Dr. Kohl-Larsen's discovery of a fossil human skull, Lake Eyasi, Tanganyika Territory". In the course of an expedition to the region of Lake Eyasi in Tanganyika Territory during 1934–36, Dr. Kohl-Larsen discovered there parts of three human skulls, together with some artefacts and fossil mammalian remains. The actual site is situated on the flats bordering the lake, and is approximately at the level to which the water rises during the wet seasons. The fossil human skull came from the so-called bone bed, a deposit of slightly consolidated sand. As the Eyasi deposits have not been disturbed, they must be subsequent to the earth movements which immediately followed the Middle Pleistocene in those regions. There seems, however, no reason, either on archæological or geological grounds, to question their late Pleistocene age, a date assigned to them by Dr. Kohl-Larsen. It may be added that the Eyasi strata contain minerals often found in Olduvai Bed 5, which also belongs to the same period.

Archæology in the Vaal River Basin

The Archæological Survey of the Union of South Africa has recently published a pamphlet entitled "Early Man in the Vaal River Basin" (Archæological Series, No. 6. Pretoria: Government Printer, 1948. 5*s*.). This interesting paper includes an article by Prof. H. Breuil on the earlier stone-age finds in the

Vaal River area; a second by Dr. C. van Riet Lowe on the older gravels of the Vaal, their industrial contents and the relationships with successive pluvial and interpluvial periods, while a third, by Dr. A. L. du Toit, is a note on the older gravels of the Vaal between Barkley West and Windsorton. Much important work is being done just now in South Africa not only in correlating the various cultural stone-age levels with the successive climate changes, but also in the intensive typological and technological study of industries made mainly from non-flint material. The raw material occurs in large blocks; and the frequent occurrence in Stellenbosch industries of the so-called Clacton platform would seem to show that this method of breaking up large blocks of raw material is in no sense typical of any particular culture, but was used freely when fashioning a nucleus from large lumps of refractory material. The diagram correlating the various phases of the Stellenbosch culture and the middle and later stone ages with the climate changes will especially interest students and give rise to some earnest thought. Dr. du Toit's note is purely geological and is concerned with the actual formation of the various gravels. This series of pamphlets issued by the Survey is always interesting; but to those concerned with correlations and the earlier industries this number is of very considerable importance.

Mortality of Adult and Young Mallards

A RECENT examination by E. O. Höhn of the recovery data of mallards (*Anas p. platyrhynca*) ringed under the *British Birds* marking scheme shows an interesting difference in length of survival of birds ringed as adults as compared with those ringed as young (*British Birds*, 41, No. 8; August 1948). Ringing recoveries of 305 adult mallards showed that 65·3 per cent died during the first year after ringing, 23·9 per cent during the second year, 6·6 per cent during the third year and 4·2 per cent during subsequent years. The average length of further survival from the date of ringing was one year and two months. Of 828 mallards ringed as young, 89 per cent died during the first year after ringing, 9·6 per cent during the second year, 0·6 per cent during the third year and 0·8 per cent during succeeding years. The average period of survival was 4·5 months after ringing. The mortality recorded by Höhn is almost entirely due to shooting.

Photometric Elements of a Binary Star

A PAPER by R. L. Baglow (*Mon. Not. Roy. Ast. Soc.*, 108, No. 4; 1948) on "The Photometric Elements of *RS* Sagittarii" is based on R. O. Redman's observations of the star, a description of which has already been published (*Mon. Not. Roy. Ast. Soc.*, 105, 212; 1945). Redman's measurements were made photographically by the Fabry method and refer to an effective wave-length of 4400 A.; these are shown in two figures together with a theoretical curve for both minima, computed by Baglow. Tables were calculated for various degrees of darkening, utilizing those given by Russell and Shapley, and elements were finally computed for an assumed coefficient of limb-darkening u equal to 0·4. The spectral type of the brighter star is given as *B*5, but that of the fainter one has not yet been observed. For the purpose of calculating the correction for reflexion it was assumed to be of type *A*0; but until its spectrum has been observed the absolute dimensions of the system cannot be accurately determined, nor can the observed ellipticity of the components be compared with theoretical expectations. Table 3 of the paper shows the dimensions of the system for three different assumptions of the mass ratio, 1·0, 0·5 and 0·2, leading to the radii of the relative orbits as 4·7, 7·0 and 14 million km., respectively. It is believed that *RS* Sagittarii is a normal eclipsing binary with a circular orbit, the secondary star being considerably less massive than the primary but comparable in size with it. Suitable spectroscopic observations of the system could greatly reduce the large uncertainties in the photometric results.

Board of Greenkeeping Research: St. Ives Station, Bingley

AT the annual meeting of the Board of Greenkeeping Research in Leeds on February 11, 1949, the director of the St. Ives Research Station, Mr. R. B. Dawson, presented his report on the Station's activities during 1948. In spite of a shortage of staff, the work has increased, and research has continued on many of the old experiments put down early in the Station's history. New work has been done on soil stabilization with bitumen, seeds mixtures, growth substances for the control of weeds, and worm control. The advisory work carried out during the year has been very heavy. Visits to subscribing clubs, the Station's postal advisory service and the number of samples from clubs which were handled by the laboratory, all showed substantial increases in the 1948 figures as compared with 1947. In addition to the pH, lime requirement and the phosphate status, the reports of the laboratory analyses of club samples now include the potash status. Golf clubs in Great Britain have continued their support, and there has been a marked increase in the support from municipalities and clubs. Educational work has been kept up in that many lectures have been given to outside bodies, and six courses of instruction for groundsmen have been arranged at the Station.

British Commonwealth Specialist Agricultural Conference in Australia

IN accordance with the resolution of the 1946 British Commonwealth Scientific Official Conference, a Specialist Conference in Agriculture will be held in Australia during August 22–September 15, 1949. The theme of the Conference is "Plant and Animal Nutrition in Relation to Soil and Climatic Factors", with emphasis on 'nutrition' interpreted broadly as well-being, and it is intended that the meeting shall consist of informal discussions between workers actively engaged in this field. The Conference, which is being organised by the Australian Council for Scientific and Industrial Research, will commence in Adelaide, South Australia, for the period August 22–31, when sessions *A*, *B*, *C* and *D* will be held. This will be followed by an official twelve-day tour through southern South Australia, Victoria and southern New South Wales, and the final sessions, *E* and *F*, and winding-up will be at Canberra during September 13–15. Official invitations have been made to each member country of the British Commonwealth, and some fifty delegates will be nominated. In addition, some invited contributors from other countries, from the United States, for example, will be attending. Travelling expenses and subsistence of the delegates will be borne by their respective countries; but the Australian Government is financing the twelve-day tour. The papers for the Conference will fall into three main groups: (*a*) officially invited papers; (*b*) contributed papers, which may be submitted without invitation and must not exceed 2,000 words; (*c*) summaries or abstracts, which are the same as (*b*) except that the limit is 500 words. Papers will not be read, but will be circulated in advance; and to facilitate printing, copies should be sent to the author's national committee immediately. Full details may be had on communication to the Secretary, Conference Committee, Specialist Agricultural Conference, c/o Council for Scientific and Industrial Research, 314 Albert Street, East Melbourne, Australia. The telegraphic address is: Coresearch, Melbourne.

Conference of Industrial Research Directors

A CONFERENCE of Directors of Industrial Research is being held during March 11–14 at Ashorne Hill, Leamington Spa, Warwickshire, under the auspices of the Industrial Research Committee of the Federation of British Industries. The chairman of the Research Committee, Sir Wallace Akers, is presiding. The subjects under discussion include relationship between the research department and management and other departments of the industrial organisation; finance and costing, laboratory administration and scientific staff, research programmes and their formulation; application of results of research to production; publications, publicity, information and intelligence; and relationship with research associations, the Department of Scientific and Industrial Research and other Government departments, and universities.

Lectures in Lausanne on the Tubercle Bacillus

A COURSE of lectures on current scientific research concerning the tubercle bacillus is being organised in Lausanne by Prof. P. Hauduroy, director of the Institute of Hygiene and Bacteriology of Lausanne, during April 21–23, 1949. The lecturers will include Prof. K. A. Jensen (Copenhagen), Prof. P. Hauduroy (Lausanne), Dr. Chain (Rome), Sir Howard Florey (Oxford) and Dr. J. Tréfouel (Pasteur Institute, Paris). The lectures will be given either in French or in English, and a summary in both languages will be distributed beforehand to members of the audience. Each lecture will be followed by a discussion. The enrolment fee is 15 Swiss francs. Particulars can be obtained from Prof. P. Hauduroy, 19 Avenue César Roux, Lausanne.

Colonial Service: Recent Appointments

THE following appointments in the Colonial Service have been announced: J. M. Hay, assistant chemist, Nigeria; C. H. Tack, forest engineer, Uganda; J. Greasley, veterinary officer, Tanganyika; P. T. Heath, veterinary officer, Uganda; G. J. Bell, professional assistant, Royal Observatory, Hong Kong; R. J. Garner, assistant meteorologist, Gold Coast; N. G. Lechmere-Guppy, assistant conservator of forests, British Guiana; A. P. Johnson, assistant meteorologist, Gambia; N. Kirby, deputy Government chemist, Jamaica; R. D. Pauwels, agricultural chemist, Kenya; J. K. Cox (agricultural officer, North Borneo), senior agricultural officer, North Borneo; J. Gordon (agricultural officer, Gold Coast), agricultural officer, North Borneo; R. D. Linton (senior agricultural officer, Tanganyika), deputy director of agriculture, Gold Coast; His Highness Tenghu Yaacob ibni al-marhum Sultan Abdul Hamid (principal agricultural officer, Federation of Malaya), State agricultural officer, Federation of Malaya; J. F. Hughes (assistant conservator of forests, Tanganyika), forest utilization officer, Tanganyika; M. S. Parry (assistant conservator of forests, Tanganyika), sylviculturist, Tanganyika; Dr. J. H. Strahan (malaria research officer, Federation of Malaya), professor of social medicine and hygiene, Singapore; L. F. Robertson (senior veterinary officer, Palestine), veterinary officer, Tanganyika; S. Simpson (senior veterinary officer, Gold Coast), director of veterinary services, Gold Coast; L. J. Chwatt (malariologist, Nigeria), senior malariologist, Nigeria; K. V. Nicholls (meteorological officer, Federation of Malaya), meteorologist, East African High Commission; G. K. Read (animal husbandry officer, Palestine), livestock officer, Tanganyika.

Announcements

H.R.H. The Princess Elizabeth, Duchess of Edinburgh, has been elected an honorary member of the Royal Institution.

SIR ROBERT ROBINSON, president of the Royal Society, has been elected an honorary member of the Parliamentary and Scientific Committee.

MR. HUGH LINSTEAD, M.P., secretary of the Pharmaceutical Society of Great Britain, has been elected a foreign corresponding member of the Academy of Medicine of France. The Academy, which is the premier medical society of France, was founded in 1820 by Louis XVIII, and its membership is limited to 270 French and 80 foreign members.

THE Bessemer Medal for 1949 of the Iron and Steel Institute has been awarded to Prof. J. H. Andrew, professor of metallurgy in the University of Sheffield.

THE University of Liverpool Chemical Society Medal for this year has been awarded to Prof. F. S. Spring, of the Royal Technical College, Glasgow. The presentation will take place at the annual open meeting of the Society, when Prof. Spring will deliver an address entitled "The Chemistry of Aspergillic Acid".

DR. J. F. DANIELLI has been appointed to the University chair of zoology tenable at King's College, London, as from October 1, 1949.

THE Rockefeller Foundation has made a grant of 15,000 dollars for the purchase, primarily, of infra-red spectroscopic equipment in the United States, for use in the University Chemical Laboratory, Cambridge, under the direction of Prof. A. R. Todd. The equipment is to be used in developing and furthering researches in that Laboratory on nucleotide and nucleic acid structure, and on other chemical investigations of biological importance.

THE second award of £50 of the Oliver Memorial Fund will be made to a British subject for a notable contribution to the research, organisation or donor aspect of blood transfusion. Applications and suggestions should be sent, before June 30, to Mr. F. W. Mills, National Provincial Bank, Ltd., Holborn Circus, London, E.C.1.

THE British Iron and Steel Research Association is to hold a conference during May 9–10, 1949, at Ashorne Hill, near Leamington Spa, to discuss the practical applications and essential theoretical treatments of phase-contrast microscopy, the multiple-beam interference technique, and the reflecting microscope. Application to attend and for accommodation at Ashorne Hill should be made to the Metallurgy Division, B.I.S.R.A., 11 Park Lane, London, W.1.

Role of Dislocations in Crystal Growth

THE theory of nucleation in the formation of liquid or solid phases from the vapour, the most detailed treatment of which in any published work is that by Becker and Döring[1,2], is in satisfactory quantitative agreement with experiment with regard to the primary nucleation of liquid droplets[1,3], which requires saturation ratios of from 3 to 6 in typical cases. The theory predicts further that the primary nucleation of a crystal from the vapour requires still larger saturation ratios, so that the critical conditions for nucleation of the liquid are reached first, unless working with very low vapour pressures far below the melting point. This is also in agreement with observation.

In the course of their treatment, Becker and Döring also deal with the two-dimensional nucleation of each new close-packed layer of molecules deposited on a crystal face, the importance of which was first stressed by Volmer. The theory indicates that just as the three-dimensional drop or crystal is far more likely to evaporate than to grow larger unless it exceeds a certain critical size, the same is true of a two-dimensional 'island' of new crystal layer on a completed crystal face, when this face is of a close-packed or 'saturated' character: for example, the (100) face of the Kossel model crystal made of cubic building blocks for which Becker and Döring made their calculations, or of sodium chloride; or the (111) face of a face-centred cubic crystal of argon.

No one seems to have noticed that the assumption that the growth of crystals from the vapour takes place in this way (by two-dimensional nucleation in the crystal surface) implies a rate of growth which is negligible at small supersaturations.

According to the theory developed by Volmer and Becker and Döring, the number of nuclei formed per second on 1 cm.^{2} of surface is

$$N \sim A \exp\{-\varphi^2/(kT)^2 \log \alpha\}, \qquad (1)$$

where A is of the order of 10^{20}, φ is the interaction energy between two molecules, and α is the saturation ratio, that is, the ratio of the concentration in the vapour to the equilibrium concentration. Experiments by Volmer and Schultze[4] in iodine at 0° C. indicate an observable rate of growth proportional to $\alpha - 1$ when $\alpha \geqslant 1{\cdot}01$. The value of φ/kT for iodine at 0° C. is about 6, so when $\alpha = 1{\cdot}01$, the exponent in (1) is about $-3{,}600$. In fact, the observed growth-rate exceeds the theoretical value by a factor of $e^{3,600}$.

Two of us (W. K. Burton and N. Cabrera)[5] have re-examined in detail the bases of the Becker–Döring theory. The most important refinement concerns the shape of the critical nucleus. Becker and Döring restricted their attention to rectangular nuclei, and found the critical one to be a square of side

$$l_0 = \varphi/kT \log \alpha \qquad (2)$$

measured in molecular spacings. We find, in fact, that it is a figure with rounded corners which can be inscribed in the same square (Fig. 1). The shape is independent of α but depends on φ/kT. Between two corners the shape is given by

$$y/l_0 = \log_e\{1-[\sinh^2(\varphi x/2kTl_0)]/\sinh^2(\varphi/4kT)\}. \qquad (3)$$

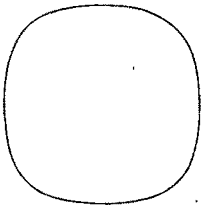

Fig. 1

The radius of curvature at the corner is given by

$$\rho/l_0 = -(\sqrt{2}kT/\varphi)\tanh^2(\varphi/2kT), \qquad (4)$$

so that the shape tends to a square in agreement with Becker and Döring at sufficiently low temperatures.

In the general case, (1) can be written

$$N \sim A \exp(F/2kT), \qquad (5)$$

where F is the edge free energy of the critical nucleus, valid for all shapes of nuclei. The effect of the correction is to reduce F in the same ratio as the area of the critical nucleus. This ratio cannot be smaller than $\pi/4$, and is, in fact, $0{\cdot}86$ when $\varphi/kT = 6$. Thus the discrepancy between theory and experiment is still about $e^{3,100}$. Other corrections, connected with the details of surface migration processes, are relatively small, and we do not believe that the estimate of the value of φ can be wrong in order of magnitude. We are forced to the conclusion that the theory, as amended, gives the true order of magnitude of the rate of growth of a perfect crystal, and it has been suggested by one of us (F. C. Frank)[6] that it can only be reconciled with the observed rate of growth of real crystals by recognizing that those which grow are not perfect.

It is believed from their mechanical behaviour that real crystals in general contain dislocations. Taylor's original conception of a dislocation has been generalized by Burgers[7] with the recognition that the unit displacement of the dislocation is not necessarily normal to the dislocation line, and may, in an extreme case, be parallel to it, in which case we have a Burgers 'screw' dislocation (Figs. 2 and 3*a*). Whenever a dislocation line which is wholly or partly screw terminates in the exposed face of a crystal, there is a permanently exposed 'cliff' of atoms in the surface, the addition of a new layer restores the initial situation, and the need for fresh two-dimensional nucleation is eliminated: with a single screw dislocation in the face, it can grow perpetually 'up a spiral staircase'. The exposed cliff now plays the part of the edge of the nucleus. In the case where there is a single dislocation in the face, if its distance l from the boundary exceeds l_0, growth will occur: if l is

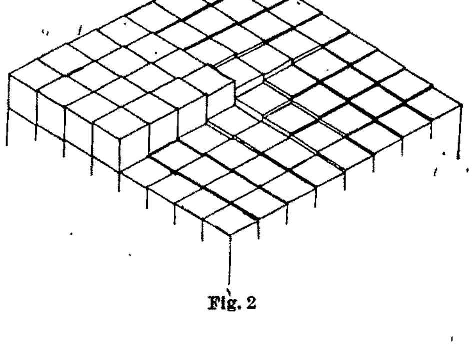

Fig. 2

less than l_0, evaporation will occur. Hence the smallest crystal which can grow by this mechanism must have a face of width greater than $2\,l_0$. This is also the critical size for three-dimensional nuclei in the classical theory. Two screw dislocations terminating in one crystal face give rise to the situation shown in Fig. 3*b*. Growth takes place freely if the distance apart of the dislocations and the distance of either of them from the edge of the face exceed l_0. The criterion $l > l_0$ for growth can be shown to be a sharp one, despite thermal fluctuations.

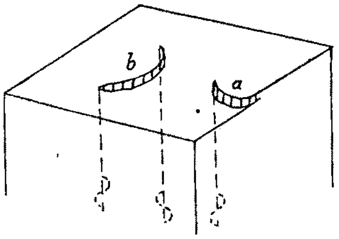

Fig. 3

We conclude that crystals do not grow at low supersaturations unless they contain dislocations. On the other hand, an excessive density of dislocations also inhibits growth, particularly at very low supersaturations: hence under these conditions we get the most nearly perfect, and yet never truly perfect, crystals. The growth of 'unsaturated' faces (for example, (111) faces of sodium chloride, or any faces of high index) is independent of dislocations or two-dimensional nucleation; but in the case of a crystal which has more than one family of relatively 'saturated' faces, which would need two-dimensional nucleation if it were perfect, it may be the dislocation structure which determines which are the slowest growing, that is, the habit faces.

Velocity of Sound in Liquid Hydrogen

In continuation of our previous measurements on the velocity of ultrasonics (frequency 523 kc.) in condensed gases at low temperatures[1], we have now measured the velocity of sound in liquid hydrogen under its saturated pressure as a function of temperature between 21° and 14° K. The experimental results are given in the accompanying table, and graphically in Fig. 1.

During the measurements, we observed a pronounced increase of the velocity of sound as a function of time. Those observations were followed specially at the boiling point, and are represented in Fig. 2. This phenomenon is not due to a temperature drift, but probably to a transformation of the normal hydrogen to para-hydrogen in the liquid phase. In connexion with this phenomenon, we observed that the values which were obtained on November 26 are larger than the earlier ones, so that we are of opinion that the later measurements correspond to a more complete transformation into para-hydrogen.

Recently, one measurement at 17 ± 1° K. on the velocity of sound by using the pulse technique has been published by Galt[2]. He found at this temperature, $v = 1{,}187$ m./sec., which is smaller than our values, so that we suppose that his measurements correspond to normal hydrogen. Pitt and Jackson[3] measured the velocity of sound at the boiling point of hydrogen; their value is also indicated in Fig. 1.

We take the opportunity to express our sincere thanks to the Fonds National de la Recherche Scientifique for financial help.

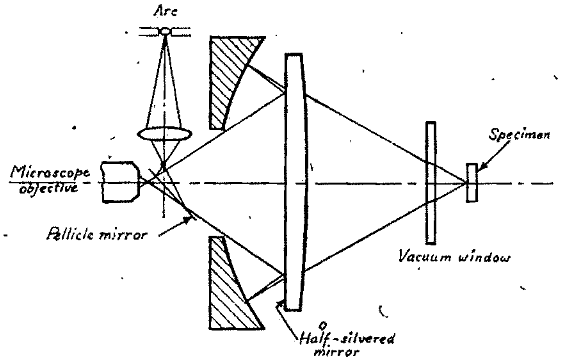
A Unit-Magnification Optical System with Long Working Distance for Microscopical Applications

Occasions frequently arise in microscopy where a working distance much greater than that given by conventional objectives for a given numerical aperture is required. This occurs in the microscopy of hot metallurgical specimens inside a vacuum furnace, the examination of electrode conditions inside a vacuum tube, various biological applications, and the examination of nuclear plates which may involve working through considerable thicknesses of glass and emulsion.



A system designed to meet the conditions of the metallurgical problem outlined above is illustrated in the accompanying diagram. A concave spherical mirror is placed so that the object is nearly at its centre of curvature. Light from the object passes through a half-silvered plane mirror and falls on the concave mirror nearly at normal incidence, is reflected back to an image nearly coincident with the object, and is reflected a second time by the half-silvered mirror to form an image behind the concave mirror, which is perforated to allow the image thus formed to be examined by a conventional microscope objective.

The side of the half-silvered mirror nearer the object is worked to a weak convex curvature which enables the spherical aberration due to the vacuum window and to the half-silvered mirror plate itself to be corrected without introducing significant coma. By this means a numerical aperture of 0·5 can be obtained, corresponding roughly to an 8 m./m. microscope objective.

An experimental system has been made giving approximately this aperture with a working distance of about 34 m./m., as against the 2 m./m. of an 8 m./m. objective. Due to parasitic reflexions, a vertical illuminator cannot be used in the observing microscope in the usual way. Vertical illumination can be obtained by placing a thin half-silvered pellicle mirror at 45° in the beam converging to the final image, and reflecting light into the system as shown. An unwanted image of the light source is formed by two reflexions at the half-silvered mirror and one at the concave mirror; the system is so disposed that this image is displaced about 3 m./m. along the axis away from the image of the specimen. The hole in the centre of the out-of-focus image of the light source, due to the perforation in the concave mirror, then occupies the whole field of the observing microscope, and the image of the specimen is not obscured.

An immersion system using the same principle, with the concave and plane mirrors formed on two sides of a glass block, has been designed for nuclear plate work. This uses a 4 m./m. objective and attains a numerical aperture of 0·75, enabling the examination of nuclear tracks through a quarter of an inch or so of glass. It is small enough to be used on a conventional microscope.

A water immersion system for biological applications has also been designed.

A fuller description of these systems, together with the theory of the corrections, will be published elsewhere.

Showers Generated in Lead by Mesons

The main source of secondary electrons produced by mesons at sea-level is the close ionizing collision in which considerable kinetic energy is transferred to the electron concerned, and from which a small cascade develops.

Many workers have observed such showers using a thickness of dense material greater than 30 cascade units in order to be sure that electrons coming from the air are excluded, and that equilibrium is reached between the meson beam and its electron secondaries[1,2]. The results obtained in this way generally agree; but with smaller collision layers, when the transition effects at the entry into the dense medium have not yet become stabilized, the agreement between different workers is not so satisfactory[3,4,5].

Clay and Venema[4] have measured the absorption of incident electrons but not the transition effect of the layer; Stuhlinger[3] has carried out correction measurements, the principle of which is certainly good, but which are not quantitatively comparable with his original data, since the area of the layer in

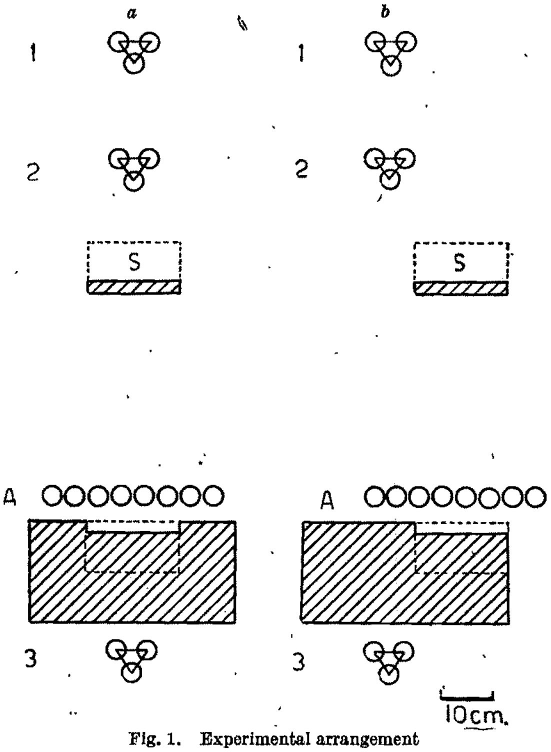

Fig. 1. Experimental arrangement

which mesons give rise to 'knock-on' electrons appears to be different from that used for the correction.

During a systematic research on showers produced by mesons, we have obtained a result which we think is of interest. The arrangement (Fig. 1) records, in addition to threefold coincidences 1, 2, 3, the number of counters triggered in the large tray *A*. Mesons give a threefold coincidence and may trigger one counter in *A*; accompanying showers may trigger further counters in *A*.

The circuit used will be described in a paper appearing shortly in *Nuovo Cimento*. The background-rate was measured using the method of Stuhlinger; but the arrangement is now changed so that the shower-generating layer is the same both for generation by mesons (Fig. 1*a*) and for the out-of-line experiment (Fig. 1*b*) which yields the correcting term. The correction can thus be applied directly.

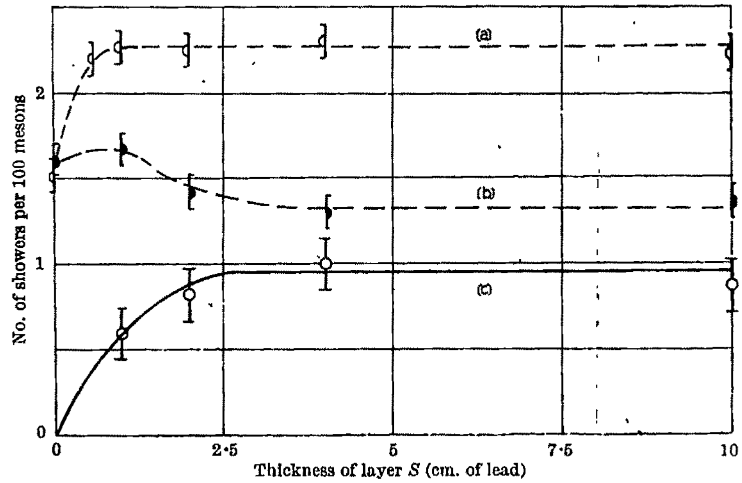

Fig. 2

In Fig. 2 we have plotted the number of showers recorded per hundred mesons as a function of the thickness *S* of the penetrating layer. Curve *a* corresponds to the arrangement of Fig. 1*a*, curve *b* to the arrangement of Fig. 1*b*, and curve *c* to the difference. Saturation is reached in curve *a* at about 1 cm. lead in agreement with the results of Stuhlinger[3] and Tongiorgi[5]. The maximum of curve *b* occurs also at the same position, as was observed by Stuhlinger. The corrected number of showers (curve *c*) is thus about 1 per cent of the number of mesons concerned.

Our arrangement is clearly insensitive to very low energy electrons, which will be very heavily scattered on leaving the lead plate. We estimate the cut-off energy to be appreciably greater than 10^7 eV. Our result is thus in general agreement with the result given by Nassar and Hazen[6], who used a cloud-chamber method to study these secondary showers.

The experiment is now being repeated using iron instead of lead.

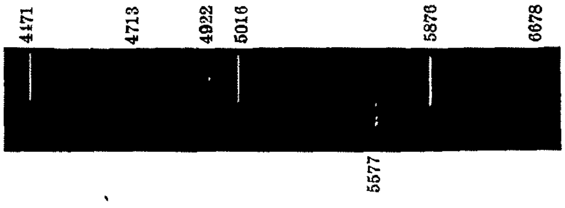
Afterglow Phenomena in Argon–Nitrogen Mixtures at Pressures Close to Atmospheric

In 1924, L. Vegard[1] directed attention to the occurrence of phosphorescent bands in the region of the auroral line at 5577·35 A. when a solidified mixture of nitrogen and argon or neon is exposed to cathode-ray excitation. In a recent communication, Vegard and Kvifte[2] report an observation of J. Nordhagen that pure argon at atmospheric pressure shows a green luminescence when excited by a Tesla transformer. Vegard and Kvifte suggest that the green band is a phosphorescent phenomenon initiated by the oxygen auroral line at 5577·35 A. They point out that increase in oxygen concentration above a certain value (not stated) suppresses the green phosphorescence.

Afterglow phenomena similar to those described by Vegard and Kvifte have frequently been observed by us when the argon–nitrogen filling of some tungsten filament lamps is excited by a Tesla transformer giving a discharge current of the order of 50 m.a. The gas-filling pressure in the lamps was 600 mm. o argon containing 8 per cent nitrogen. The accompanying spectrogram, taken in 1945, on an Ilford *HP* 3 plate shows the green oxygen line at 5577 A. and the band emission from the afterglow in the region 5600–5400 A. There is no trace on our photograph of the red band observed by Vegard in solidified gases.

It is known that the amount of oxygen in the lamps was certainly less than 4 p.p.m. of the gas filling. As little as 50 p.p.m. of oxygen or water vapour introduced into the lamp quenched the afterglow; hydrogen in similar amount had little or no effect. Burning the lamp for a hundred hours or so usually caused a gradual decrease in the intensity of the afterglow, and the optimum glow appears to occur at a concentration of oxygen probably considerably less than 1 p.p.m. Attempts to reproduce the afterglow in a lamp containing 'spectroscopically pure' argon under the same conditions have so far been unsuccessful, and our experiments show that nitrogen is a desirable, if not an essential, constituent of the gas filling.

In addition to the green afterglow we have sometimes observed in certain argon–nitrogen filled lamps afterglows lasting about a second of various colours from red to purple, the latter being indistinguishable in colour from that of the primary discharge. We have not as yet been able to record these afterglows photographically; but it is possible that the reddish



Tesla-discharge in an argon–nitrogen mixture, showing green auroral line and associated phosphorescent band (lower spectrum); discharge in helium (upper spectrum) glow is merely a rather feeble development of the well-known nitrogen afterglow.

Cathodo-Luminescence of Rare Earths in Coal Ash

BY cathodo-luminescence I have detected[1] the presence of rare earths in certain minerals in quantities too small to be detected by arc spectrographic analysis.

Samples of a number of Indian coals (from Darjeeling, Assam, Raniganj, Jharia and Hyderabad) were incinerated in thin layers in porcelain basins in an electric furnace at 400° C. The presence of rare earths in the ashes so obtained could not be detected by arc spectrographic analysis with a current of 10 amp. and 220 volts, with an E_1 quartz spectrograph using pure carbon rods. Cathodo-luminescence was then tried. The coal ashes as obtained did not show any luminescence when excited by the cathode rays. But after mixing the ash with a sufficient quantity of calcium oxide, the cathode rays induced bright luminescence. This was caused by the presence of manganese acting as an activator in the presence of calcium oxide. When rare earths were also present in the coal ash, the manganese band was suppressed by the activating action of the rare earths. It was found that the best condition for excitation of the specimen was at a potential of 4,000 volts, the current in the tube being kept at 4 milliamp. The luminescence was then so bright that the time of exposure required for taking a spectrogram was 3–7 min. with the direct-vision spectrograph and 5–12 min. with the Fuess quartz spectrograph. Urbain's data for the different systems for rare-earth oxide in calcium oxide were taken as reference in identifying the line-like bands of the luminescence spectra of the specimen.

The rare-earth activators for luminescence in coal-ash were samarium, dysprosium, europium, erbium and probably terbium and neodymium. It was found that the luminescence of the ash from only a few samples of coal from Darjeeling, Assam and Hyderabad was caused by the presence of rare earths. Luminescence of all the ashes from samples of coal from Raniganj and Jharia was caused only by manganese. Some of the samples of ash contained rare earths in sufficient quantity completely to suppress the luminescence spectrum of manganese in the visible region. With smaller quantities of rare earths, both the rare earths and the manganese behaved as activators for luminescence. Those rare earths with even atomic numbers (samarium 62, dysprosium 66) were found to be the chief activators for luminescence.

Thanks are due to Prof. P. B. Sarkar, for helpful discussions, to Prof. M. N. Saha, for allowing me to use the spectrograph, and to the Director of the Geological Survey of India, for supplying the samples of coals.

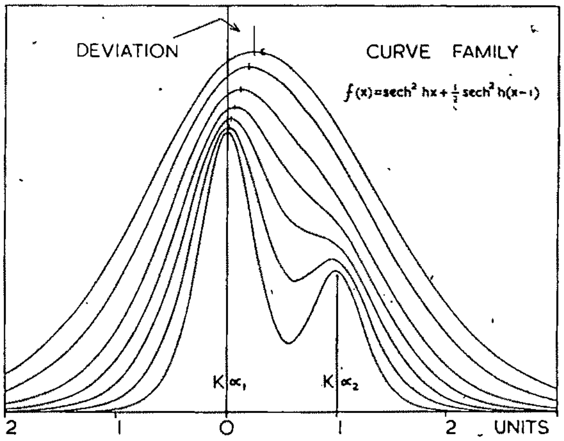
A Correction to the Diameter Measurement of Diffuse X-Ray Diffraction Rings

LATTICE parameter measurements of cold-worked metals are subject to an appreciable error if no provision is made for the lack of coincidence between the $K\alpha_1$ peak and the apparent peak, as measured, of the broadened doublet. This is indicated in the synthesized curves of the accompanying figure.



The geometrical subtraction method proving laborious, and in many cases uncertain, the following method of correction has been applied in recent work to obtain a better figure for lattice parameter. It depends upon a relationship determined between the width at half maximum intensity and the deviation between the $K\alpha_1$ and the apparent peak of the photometered doublet.

It was found that the practical doublets, when corrected for film response, approximated reasonably to the sum of two curves of the form

$$y = \text{sech}^2 hx,$$

the constant h being typical of a particular degree of broadening.

The $K\alpha$ doublet was synthesized from two such curves, having an intensity ratio of 2 : 1 and a unit $K\alpha_1 - K\alpha_2$ separation. This sum curve was defined by the following equation:

$$f(x) = \text{sech}^2 hx + \tfrac{1}{2}\,\text{sech}^2 h(x-1). \qquad (1)$$

Differentiation provided the condition for the maximum of this curve:

$$\text{sech}^2 hx.\ \tanh hx = -\tfrac{1}{2}\,\text{sech}^2 h(x-1).\ \tanh h(x-1). \qquad (2)$$

The sum curve (1) was plotted for a particular value of h, and the approximate abscissa for the peak estimated.

Open-scale plots were then made, for a small range of abscissa values about the approximate value, of $f'(x) = \text{sech}^2 hx.\ \tanh hx$ and $f''(x) = \frac{1}{2}\,\text{sech}^2 h(x-1).\ \tanh h(x-1)$. The intersection of these two lines gave the correct peak abscissa, with reference to the foot of the $K\alpha_1$ peak as origin. Substitution in equation (1) provided the corresponding ordinate.

To determine the half-width, an estimate of the positive and negative abscissa values was obtained from the plotted sum curve, and, using form (1),

$f(x)$ was plotted against x around each half value, to an open scale. The correct abscissæ were read from these plots at a value of $f(x)$ equal to half the peak ordinate already determined.

Repeating for various h values, chosen to cover the required field of broadening, a calibration was plotted of peak deviation against half-width of the sum curve. This calibration tended asymptotically towards deviation values of zero and of one third of the $K\alpha_1 - K\alpha_2$ peak separation. The accompanying figure shows a curve family for equation (1) for values of the constant h from 0·85 to 3·0.

The correction method can be modified to overcome the practical uncertainty of true film background level. Thus the practical background-level can be drawn to intersect the skirts of the doublet at some arbitrary distance on either side of the peak value. The correction curve is modified to a corresponding zero-ordinate level, which will vary with the degree of resolution of the doublet. The doublet width thus measured will not be the conventional half-width.

An error of about 15 per cent may be allowed in the correction method, as this compares favourably with the error in the peak estimation of diffuse doublets.

Applied to individual results, the method would prove tedious; but in cases where a large number of readings are to be analysed, or the use of a monochromator is impracticable, it will be found to provide rapidly an improved figure for lattice parameter.

Peak deviations found in recent experiments with steel tensile bars have amounted to the equivalent of 0·04 per cent in lattice parameter, of great significance in residual strain or similar determinations.

Department of Metallurgy,
University of Sheffield.

Plotting Electron Trajectories

A NEW method of tracing electron trajectories in electron optical systems has been developed in this Laboratory. The method consists essentially in the use of a differential analyser to integrate the equations of motion of an electron, the components of acceleration of which are continuously determined by automatic measurements in an electrolytic tank.

The present tank is of the type using half-section models of the electrode system under investigation, with the surface of the electrolyte corresponding to a plane of symmetry. The longitudinal and radial components of electric field are measured by the voltages between three suitably placed probes mounted on a movable carriage. These voltages have to be converted into proportional rotations to be suitable for feeding the differential analyser, and this is done by means of self-balancing linear potentiometers, embodying conventional follow-up servomechanisms. A third similar potentiometer is used to keep the probes at approximately earth potential.

The rotations are each fed into a pair of integrators of the differential analyser in cascade, the outputs from the first integrators of each pair representing velocities, and those from the second, displacements. The displacements are coupled back to the probe carriage so that the system continuously integrates the equations of motion of an electron and the probes move along an electron path.

Tests have been carried out on an electrostatic two-cylinder lens, and the results agree adequately with the theoretical ones available. The lens used had a gap-width of 0·8 radii. Numerical integration has been done by Goddard[1] for the case of zero and unity gap-widths, while calculations of the spherical aberration coefficient C are available for zero gap-width only[2]. For an acceleration lens of voltage ratio 4·9 we find:

Gap	f/R	C	
$0{\cdot}8\,R$	7·95	105	measured
0	7·85[1]	120[2]	calculated
R	8·25[1]	—	

The accuracy is estimated at 1 per cent for f and rather worse for C.

In addition to simple ray tracing, including skew paths, the machine appears to be suitable for solving more complicated problems, including the effect of space charge, both by exact and approximate methods, and tracing trajectories in time-varying fields. It is possible to allow exactly for relativity effects.

The differential analyser has already been described[3], and our thanks are due to the Director of the Cambridge University Mathematical Laboratory for making it available to us.

It is hoped to publish a detailed description of the apparatus at an early date.

Absolute Power Measurement at Microwave Frequencies

Nichols and Hull[1] have verified the Maxwell–Bartoli theory of radiation pressure experimentally to within 1–2 per cent by a torsion balance method, with a light beam carrying a power of about 0·1 watt.

Experiments are being made in the application of a similar technique to the absolute measurement of power at microwave frequencies. The power P to be measured is fed through a compensated waveguide T-junction[2] to a matched load. The third leg of the T-junction (preferably a circular guide supporting the H_{01}-mode) contains a movable short-circuiting plate so placed that no reflexion occurs at the junction. It can be shown that the force on the plate is $\frac{P}{2c} \cdot \frac{\lambda}{\lambda_g}$, where c is the velocity of light, λ the free space wave-length, and λ_g the guide wave-length in the third leg.

Measurement of this force is sufficient to determine P, knowing λ and λ_g.

Deformation of Single Crystals of Tin in Solutions of Oleic Acid

THE work of Rehbinder and his co-workers on the effect of surface-active substances on the strength of crystalline solids has been followed with considerable interest in this laboratory. In a paper published with Lichtman and Maslennikov, Rehbinder[1] reports a 50 per cent decrease in the yield value of single crystals of tin and zinc when immersed in a 0·2 per cent solution of oleic acid in a non-polar paraffin oil. He also reports a five-fold increase in the electrical resistance of a single crystal of tin when elongated almost to fracture in the same solution, in comparison with the resistance of a specimen of the same orientation similarly extended in air. These effects are ascribed to the opening and extension of the micro-cracks in the crystal by the 'wedging action' of a film of liquid drawn into the micro-cracks by an adsorbed layer of oleic acid molecules. This principle of 'adsorption reduction of hardness' has been widely applied in various processes for the mechanical destruction of brittle bodies[2].

Crystal No.	Condition	Peak stress (gm./mm.^{2})	Elongation at peak (%)	Angle between specimen axis and		Critical shear stress S (gm./mm.^{2})
				slip plane χ_0	slip direction λ_0	
4·10	As prepared (*a*)	123	2·6	43	46	58
	Clean (*b*)	132	2·4			63
	Clean in paraffin (*c*)	112	1·0			53
	Clean in solution of oleic acid (*d*)	125	4·1			59
3·5	As prepared (*a*)	124	1·3	48	49	61
	Clean (*b*)	119	1·9			58
	Clean in paraffin (*c*)	108	0·8			53
	Clean in solution of oleic acid (*d*)	111	1·1			54
3·7	As prepared (*a*)	136	0·8	30	30	59
	Clean (*b*)	124	1·8			54
	Clean in paraffin (*c*)	129	1·3			56
	Clean in solution of oleic acid (*d*)	134	0·5			58

This effect is obviously of considerable importance for the theory of metallic friction and boundary lubrication. It was therefore decided, as a prelude to further work on the effect of surface-active substances on metallic friction, to repeat Rehbinder's experiments, using so far as possible the technique described by him.

The specimens used were single crystals of tin (99·98 per cent pure) approximately 1 mm. in diameter and 13 cm. in length prepared by the Kapitza method[3]. Orientations were determined by X-ray rotation diagrams and in some cases checked by goniometer measurements of etch pits. Taking the slip system[4] as (110) [001], crystals were selected the orientations of which were near $\chi_0 = 45°$, since Rehbinder and Lichtman[5] report that the depression in yield value is a maximum at this orientation (χ_0 is the angle between specimen axis and the slip plane). Each crystal was then cut into six specimens, four for tensile tests, and two for electrical resistance measurements.

Tensile tests were carried out using a Polanyi-type apparatus[6], the four specimens of one crystal being tested under the following conditions: (*a*) in air, as prepared, with an oxidized surface; (*b*) in air, but cleaned for two minutes in *N* hydrochloric acid, washed in hot water, dipped in *N* ammonium hydroxide to neutralize any remaining acid, again dipped in very hot water and allowed to dry in air; (*c*) cleaned as in (*b*) and immersed in B.P. paraffin oil; (*d*) cleaned as in (*b*) and immersed in the same paraffin oil with 0·2 per cent oleic acid by weight added.

The absolute rate of extension was constant, and the rate of elongation of individual specimens, which depended on their initial length, varied from 0·2 to 0·35 per cent per minute.

The results of three typical tests are given in the accompanying table. All tensile curves showed a definite peak at approximately 2 per cent elongation. The critical shear stress in the (110) [001] slip system was calculated from this peak stress.

It will be seen that, under the conditions of these experiments, alteration of the surface condition produces no significant change in the critical shear stress.

Similar negative results were obtained with a series of crystals in which χ_0 varied from 30° to 60°, at rates of elongation of 0·2–4 per cent per minute.

In his paper, Rehbinder does not specify the particular paraffin used. Since it seemed possible that the viscosity of the solution might have some effect on the magnitude of the 'wedging action', the experiments were repeated using hexadecane and kerosene as solvents to provide a wide range of viscosities. Again no effect was observed.

The two remaining samples of crystals used in the tensile tests were then elongated almost to fracture (150–200 per cent elongation) in air and in the original oleic acid solution. For the same elongation, no significant difference in electrical resistance was observed.

In view of the very large effects reported by Rehbinder, and of their wide application, these negative results are put forward with some diffidence in the hope that workers in other fields may be able to offer some explanation. Further work is in progress with other metals and surface-active compounds.

This work forms part of the general research programme of the Division of Tribophysics, Council for Scientific and Industrial Research. My thanks are due to Dr. S. H. Bastow for directing my attention to the problem and to Dr. W. Boas for helpful discussions.

Oxalacetate Decarboxylation by Iron and Copper

The catalysis of oxalacetate decarboxylation by metallic ions constitutes a simple 'model' system, the properties of which may throw some light on the biological decarboxylation mechanisms. Kornberg, Ochoa and Mehler[1] have described the formation of an unstable complex between oxalacetate and aluminium ions, which possesses a characteristic ultra-violet absorption spectrum. Recent studies from this laboratory[2] have shown that iron and copper differ in many respects as regards their ability to accelerate the decomposition of oxalacetate.

The effects of iron and copper were therefore examined in the light of their ability to form complexes such as that with aluminium. A Beckman Model *DU* quartz spectrophotometer was used, measurements being made at room temperature in 1-cm. cells. The 100 per cent transmission blanks contained all the constituents of the experimental cells except oxalacetate.

The ultra-violet spectrum of oxalacetate depends intimately on *p*H. The light-absorbing constituent (that is, either the enol tautomer or possibly the oxalacetate ion) increases with increasing *p*H. It might be expected, therefore, that formation of complexes involving this form (as suggested to occur for aluminium ions by Ochoa's team) would be maximal at high *p*H values. This is found to be the case with cupric ions, *but not with ferric ions.*

In unbuffered solutions, the absorption spectra of the ferric and cupric complexes resemble each other closely, both possessing very marked bands with maxima at 270 mμ. The ferric complex, however, shows an additional faint band extending from 355 to 375 mμ. The copper complex decomposes much more readily than that of iron when the same metal concentration is used. Whereas the copper complex forms almost spontaneously (that is, in less than 30 sec.) at acid *p*H, the iron complex formation reaches a maximum only after 1–5 minutes (depending on the oxalacetate to ferric iron ratio).

Ferrous iron did *not* cause formation of a complex resembling the above two. This is unexpected, as manometrically ferrous iron has been shown to be an active oxalacetate-decomposing agent[3]. However, since that work was carried out at 38° C. in acetate buffer, and a strong oxygen uptake was observed, it may be assumed that conversion to ferric iron preceded the decomposition of oxalacetate. Results of the spectrophotometric examination suggest that ferrous iron as such may not be a catalyst for the decarboxylation of oxalacetate.

The effect of *p*H on the rates of formation and decomposition of the two metal-oxalacetate complexes shows that, in the case of iron, formation of the complex is maximal at the lowest *p*H. The decomposition-rate does not vary greatly from *p*H 1·1 to *p*H 3·2, but is much slower at *p*H 4·5. A steady rise in optical density at and above *p*H 6 was so unusual that the spectrum produced under those conditions was re-examined. It was found that the absorption peak at 270 mμ *was no longer formed*, and that the whole spectrum resembled that of oxalacetate alone. However, in the presence of ferric iron, the whole spectrum was of higher density. Thus, the effect of ferric iron at and above *p*H 6 seems to be to increase the amount of the light-absorbing form of oxalacetate without forming a complex.

In the case of copper, complex formation increases with increasing *p*H, and thus appears to be dependent on the amount of enol-oxalacetate or oxalacetate ions present. The decomposition-rate appeared to be maximal between *p*H 3·5 and *p*H 4·5, decreasing sharply on either side of that range.

These results confirm the differences between cuprous and ferric ions observed in the manometric work, and show once again the intimate connexion between catalytic effectiveness and *p*H. The investigation is being extended to the effect of buffers, and to the blood catalysis. Full details of this work will appear in the *Australian Journal of Experimental Biology and Medical Science.*

I wish to thank Mr. H. R. Marston for the use of the spectrophotometer, and M. L. Wellby for technical assistance.

This work was carried out as part of the programme towards elucidating the mechanism of oxalacetate decarboxylation by blood[4,3,5].

Effect of Acridine Compounds on the Respiration of the Brain of the Six-Day Chick Embryo

In relating the effect of certain acridines on mitosis to that on respiration, the inhibition of the oxygen consumption of the isolated brain of the six-day chick embryo by these compounds has been measured. It is thought that a note on these results would be of interest as a comparison with the results of Albert and Marshall[1] on chick red cells infected with *Plasmodium gallinaceum.*

Compound	Percentage inhibition of respiration of isolated chick brain at concentration of :			Concentration producing pycnosis of dividing cells
	1 : 12,000	1 : 6,000	1 : 3,000	
5-Aminoacridine hydrochloride	14	31	45	1 : 125,000
5-Amino-1-phenyl-10-methylacridinium bromide	nil	nil	nil	1 : 55,000
5-Amino-10-methyl-acridinium bromide	nil	nil	nil	1 : 140,000
5-Amino-2-trifluoromethyl-acridine hydrochloride	68	100	100	1 : 110,000

These results were obtained by a modification of the Cartesian diver micromanometer, using buffered Tyrode solution as a medium, and are interpolations from curves relating inhibition of oxygen consumption to concentration.

Exposure of the isolated brain tissue to the acridine compounds resulted, within two hours, in swelling and fusion of the chromosomes in dividing cells (pycnosis). The concentrations producing this change are recorded in the table; at such concentrations there was no measurable inhibition of respiration.

Properties of Branched Aliphatic Acids and their Behaviour in the Dog

In Fig. 1 are seen on the right the melting points and the tolerated amounts of alkylated succinic acids; on the left the behaviour of β-alkyl-adipic acids plotted in the same manner. Both pairs of curves demonstrate a curious concordance between the purely physical attributes of melting point and the biological behaviour in the dog. We have also studied the properties of acids with longer side-chains, but have not plotted these values in the figures. The curves differ more as the number of carbon atoms in the side-chains increases, the melting points ascending more slowly than the tolerated amounts. The concordance of the curves, we conclude, is connected with the steric hindrance of the short side-chain, which renders the growth of crystals more difficult, as well as the apposition to oxidative enzymes.

In order to learn more about the steric and energetic behaviour of such branched acids, we prepared α-alkylated stearic acids with 1–12 carbon atoms in the side-chain.

In Fig. 2 the melting points are shown; oscillation between the odd- and even-numbered branches is clearly seen. Only substrates of a very high degree of purity can be used for these studies; the usual alkyls of natural occurrence have, therefore, been replaced by substrate successively synthesized from short alkyl bromides and ethylene oxide.

The minimal areas of each acid according to the monomolecular film method of Langmuir (monolayers on water) are seen in Fig. 3. These areas, 19·5 A.^{2} for normal stearic acid, quickly increase from methyl to butyl; the areas increase more slowly from pentyl to heptyl, and they remain unchanged from octyl upwards. The curve of the *maximal* areas obtained for all acids under the same conditions has the same direction. From these results we conclude that the short alkyl groups, up to and including butyl, lie crosswise to the main chain, from pentyl to heptyl are mobile, and from octyl upwards the branched groups are bent back on themselves to lie parallel to the main chain.

The methylated higher acids are biologically important in respect to their occurrence in steroids, isoprene derivatives and in lipids of acid-fast bacteria. The acids we have synthesized are shown in the table.

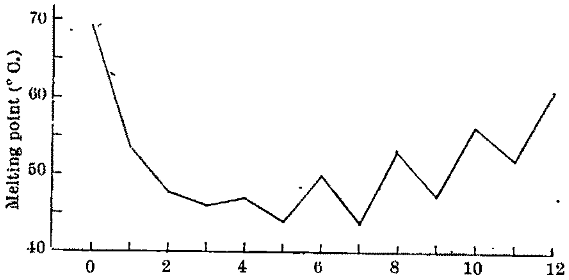

Fig. 2. α-*n*-Alkyl-stearic acids. Melting points

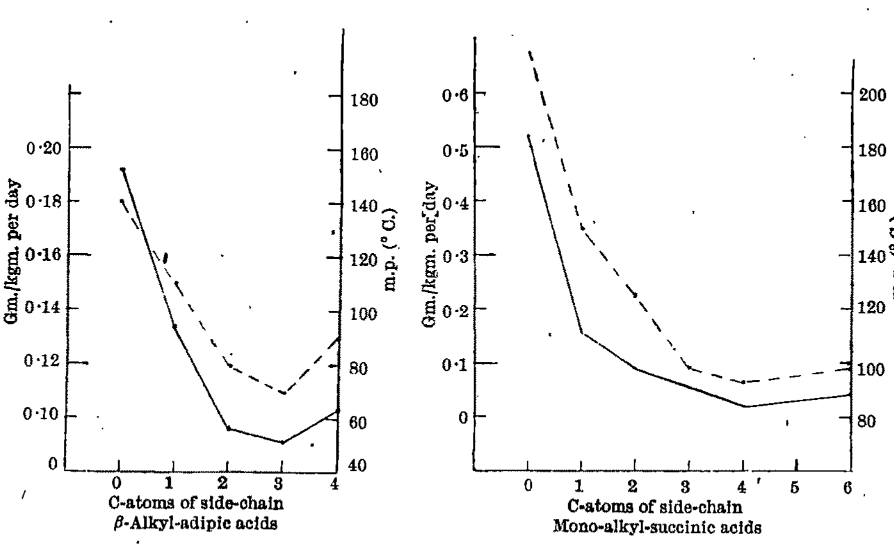
Branched-chain fatty acids used

Main-chain		M.p.
C_{18}	α-Methyl-stearic acid	54°
C_{18}	β-Methyl-stearic acid	49°
C_{18}	γ-Methyl-stearic acid	50·5°
C_{19}	β-Methyl-nonadecanic acid	48°
C_{18}	α-γ-Dimethyl-stearic acid	39°
C_{17}	α-β-Dimethyl-margaric acid	43°
C_{18}	α-Ethyl-stearic acid	48°
C_{16}	3,7,11,15-Tetramethyl-palmitic acid (= phytanic acid)	liquid at room temp.
C_{12}	α-Methyl-dodecanic acid	,, ,, ,, ,,
C_{12}	3,7,11-Trimethyl-dodecanic acid	,, ,, ,, ,,

We studied the behaviour of all acids in the same two dogs, *S* and *T*; our results are shown in Fig. 4.

Each dog was fed in each experiment with the same amount, namely, 25 gm., of the respective acid at the beginning of the first day. The urines of the first and the following three days were collected separately, acidified and extracted with ether; the extracts were separated as steam volatiles containing mainly monobasic acids, and as ether solubles, but not as steam volatiles containing mainly dibasic acids. In Fig. 4 the height of the columns indicates milli-equivalents acid in the total urine for four days; the blank values over the same space of time lie between 4·0 and 6·4 milli-equivalents. It is seen that monomethylated acids are freely oxidized, no residues appearing in the respective urines. The same is the case with repeated methylated acids; from which it may be anticipated that the methyl groups are not in the α-β-position, but farther apart, in the α-, γ, or α-, δ-positions. If that is so, as in phytanic acid, the even 4 methyl groups in one molecule are totally tolerated. Ethyl in the α-position hinders the oxidation, but only partially. We fed 25 gm., or 76·4 milli-equivalents, of it, and obtained only 4–6 milli-equivalents residues, or 5–8 per cent. Two neighbouring methyl groups in the α-, β-position hinder the oxidation considerably more, as already said, but not completely: from 76·4 milli-equivalents, or 12 per cent,



C-atoms of side-chain

Mono-alkyl-succinic acids

Fig. 1. Melting points and tolerance

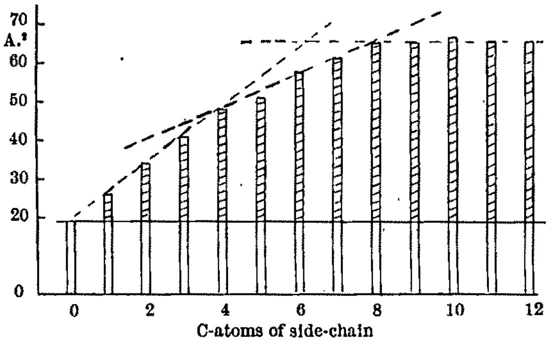

Fig. 3. α-n-Alkyl-stearic acids. Minimal areas

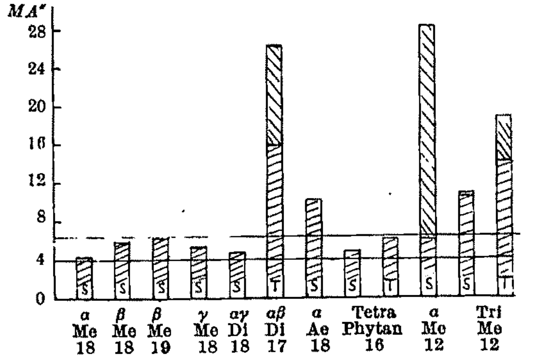
in the non-volatile fraction, and in addition the same level in the volatile fraction.

We found, further, that the totally consumed main-chain must be composed of at least sixteen carbon atoms or more; shorter chains, as in dodecanic acid, will not be oxidized so freely; one methyl alone attached to C-atom 2 hindered oxidation more than three methyl groups in the 3, 7, 11-positions to the carboxyl. We believe that the higher acids form better solid films in the lipids of the cell than they do spread out on a water-air interface. Equally they are held more firmly by the oxidative enzymes, and therefore they are better tolerated in the body.



4–6, 4 *MA″* = Normal excretion, 4 days.
Upwards shading = Ether solubles, not steam-volatile acids
Downwards shading = Ether solubles, and steam-volatile acids.

Biological Deacetylation of Acetamido Compounds and Formation of Benzoxazolone

IN a recent paper, Smith and Williams[1] discuss the fact observed by Jaffé and Hilbert[2] that acetanilide is hydroxylated by the dog mainly in the *ortho* position and by the rabbit only in the *para* position. They postulate that this difference may be due to the different degrees of deacetylation which take place in the two animals. The dog is known to be much less efficient than the rabbit in acetylating the aromatic amino group[3,4], although it is able to acetylate aliphatic amino groups, as in the formation of mercapturic acids[5]. The deacetylation of acetanilide in the dog does not appear to have been reported upon but we have observed, in agreement with Smith and Williams, that the rabbit deacetylates it to only a slight extent (not more than 2–3 per cent). The deacetylation of acetylsulphamezathine by the dog and rabbit has been studied by Krebs, Sykes and Bartley[6], who found that the former deacetylates about 29 per cent of an injected dose whereas the latter deacetylates only 1 per cent in the same time. It would therefore be expected that considerable deacetylation of acetanilide would occur in the dog.

The preliminary results of an investigation in progress in this laboratory have an indirect bearing on this problem. Jaffé and Hilbert reported the isolation of benzoxazolone as a metabolite of acetanilide in the dog, but not in the rabbit; and although it has frequently been suggested that this was an artefact, so far as we are aware no clear experimental evidence to this effect has been presented. We have now shown that if normal rabbit urine to which *o*-aminophenol has been added is treated by the procedure used by Jaffé and Hilbert (namely, evaporation to dryness, extraction of the residue with alcohol and treatment of the alcohol-soluble material with boiling 2*N* hydrochloric acid, followed by extraction with ether) benzoxazolone can be isolated as its monohydrate (m.p. 95°). This was characterized as its benzoate, m.p. 171°. If, however, *o*-acetamidophenol is used instead, benzoxazolone cannot be detected. This result, therefore, suggests that if no deacetylation of acetanilide occurred in the dog, the procedure employed by Jaffé and Hilbert would not have resulted in the formation of benzoxazolone, which appears to take place during the preliminary evaporation of the urine.

We are also engaged upon a study of the deacetylation process *in vitro*. This has shown that dog liver is much more active in deacetylating acetanilide than is rabbit liver, the average percentages hydrolysis in twenty hours under comparable conditions being 76 and 26 respectively. Although the exact relationship between *in vitro* and *in vivo* deacetylation cannot be assessed, it is probable that our *in vitro* results reflect the process in the intact animal. Our experiments have, moreover, provided evidence for the existence of different deacetylases for aliphatic and aromatic acetamido compounds. Dog liver deacetylates acetanilide readily (76 per cent in twenty hours) but acetylglycine only slightly (11 per cent in the same time). With rabbit liver, however, the converse is true, acetanilide being hydrolysed to an extent of 18 per cent in twenty hours and acetylglycine 98 per cent. In this tissue, drying by acetone results in the destruction of the 'aromatic' deacetylase whereas the 'aliphatic' deacetylase activity is unimpaired. These results may be interpreted as lending support to the suggestion put forward by Stekol[5], which has been substantiated by the results of work by Bloch and Rittenberg[7], that the biological processes for acetylating aliphatic and aromatic amines are separate processes.

A fuller report of this investigation is in preparation for publication.

Role of Hydroxylamine in Biological Fixation of Nitrogen

The position of hydroxylamine as an intermediate in the nitrogen fixation process has become increasingly doubtful as a result of recent studies[1,2]. No direct attempts have been made, however, to find the effect of hydroxylamine on nitrogen fixation. An application of the isotope tracer method to this problem is being made in these laboratories, using nitrogen containing 30 per cent nitrogen-15. A large 18-hour-old culture of *Azotobacter vinelandii* in a nitrogen-free mannitol medium was aseptically subdivided into equal 100-ml. portions, and 1 ml. of suitable dilutions of buffered hydroxylamine added to give the concentrations required for inhibition measurements. The cultures were then aerated in parallel with an atmosphere containing nitrogen (partial pressure, 0·25 atm.), and oxygen (partial pressure, 0·2 atm.)—the nitrogen being 'heavy'—in a thermostat at 29° C. After a four-hour period of aeration, the cells were collected, and nitrogen samples prepared for isotope analysis. The following analyses were obtained:

$[NH_2OH]$	0	10^{-4} *M*	10^{-3} *M*	10^{-2} *M*.
% N^{15} excess over normal	1·14	0·427	0·003	0·001

This represents 63 per cent inhibition of nitrogen uptake at 10^{-4} *M*, and virtually 100 per cent inhibition at 10^{-3} *M* and higher. Hydroxylamine is well known to be a powerful respiratory inhibitor[3], and since nitrogen fixation is an endothermic process, it should be inhibited also[1]. If hydroxylamine is an intermediate in the fixation process, it can be expected to replace molecular nitrogen in the metabolism of the bacteria, and this effect will, therefore, be reflected in greater inhibition of nitrogen fixation than respiration, for a given concentration of hydroxylamine. A provisional comparison may be made with the results of respiration experiments of other workers. Wilson and Wilson[3] report 90–100 per cent inhibition at 10^{-3} *M*, and 90 per cent at 10^{-4} *M*, with *Azotobacter vinelandii* in a succinate medium. Endres[4] reports approximately 60 per cent inhibition at 10^{-4} *M*, and 90 per cent at 10^{-3}, with *Azotobacter chroococcum* in a glucose medium. The inhibition of nitrogen fixation, therefore, does not appear to be greater than the inhibition of respiration, although a final comparison cannot be made until experiments designed to permit this, and proceeding here, have been completed with the strain of *Azotobacter* available.

Parallel experiments are being made to find the effect of hydroxylamine on the growth of *Azotobacter* on gaseous nitrogen. The organisms were cultured in various concentrations of hydroxylamine, and growth measured by direct counting. Growth was supported indefinitely in a solution of initial concentration 10^{-4} *M*, for one subculture only at 10^{-3} *M*, and not at all at 10^{-2} *M*. Long lag phases were observed, however, growth being apparently delayed until the concentration of hydroxylamine had decreased to less than 5×10^{-5} *M* in the first subculture, which agrees with the observations of Novak and Wilson[2]. The lag increased from a few hours in the first subculture at 10^{-4} *M*, to three days at the sixth. Further experiments, which are being continued, indicate that the rate of removal of hydroxylamine from a culture medium is independent of the presence of the bacteria, even with six previous subcultures at 10^{-4} *M* (comparing with Lewis and Hinshelwood's observations[5]). Experiments here have shown that the levels of ammonia in culture solutions of *Azotobacter* supplied with hydroxylamine were higher than those not similarly supplied. This, together with the above observations on the rates of removal of hydroxylamine from such solution, suggests the liberation of nitrogenous materials from the cells in the presence of hydroxylamine, rather than the reduction of the latter, as postulated for the symbiotic system by Virtanen[6]. The liberation of nitrogenous substances was confirmed by Kjeldahl analyses.

The results of these studies support those from the isotope-tracing experiment above in suggesting that hydroxylamine is unlikely to be one of the stable intermediates of nitrogen fixation by *Azotobacter*.

The isotope abundance measurements were made by one of us (E. R. S. W.) on a Nier-type, 60° sector mass spectrometer, with electronic circuits described by Graham *et al.*[7]. We wish to express our indebtedness to Dr. S. E. Jacobs for his continued interest and advice.

Effect of *p*H on the Activity of some Respiratory Inhibitors

Changes of *p*H have been shown to influence the activity of certain respiratory inhibitors, for example, iodoacetate[1], azide[2], fluoride[3] and malonate[4]. We have been led to a detailed investigation of the effects of *p*H change on some of these inhibitors since they are all the salts of weak acids, and one of us (E. W. S.) has recently examined the influence of *p*H on the fungistatic action of weak acids allied to phenol[5].

The Warburg manometric technique was used to measure the rates of oxygen uptake by suspensions of

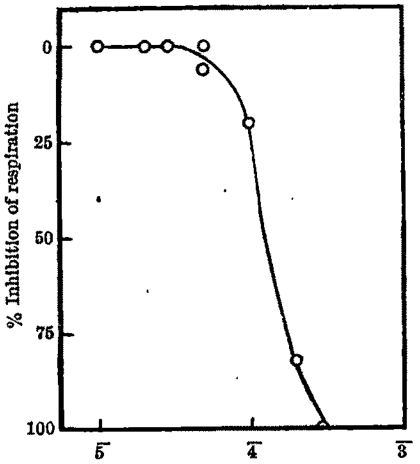

Fig. 1. Inhibition of yeast respiration by sodium iodoacetate at *p*H 4·8

baker's yeast in *M*/15 phosphate buffers containing *M*/5 glucose. In a typical experiment, each vessel contained 2 ml. 0·5 per cent yeast suspension at one *p*H level (measured colorimetrically) and 0·5 ml. of the respiratory inhibitor at the desired concentration. The experiments with sodium iodoacetate were carried out at 30° C. and the (constant) rates of oxygen uptake were measured after twenty-one hours.

Fig. 1 shows the effect of increasing concentrations of iodoacetate on the respiration-rate of yeast at *p*H 4·8. Concentrations below 5×10^{-5} *M* have no inhibiting effect, but at higher values the curve falls sharply and at 3×10^{-4} *M* inhibition is complete. We have obtained equally steep sigmoid curves from experiments at various *p*H values between 2·3 and 7·8. To find the effect of change of *p*H on the activity of the inhibitor, we have determined the concentration of inhibitor required to give 50 per cent reduction of the respiration-rate at several *p*H-levels. From Fig. 1 it can be seen that the concentration required to halve the respiration-rate at *p*H 4·8 is $1 \cdot 3 \times 10^{-4}$ *M*. The logarithm of this value and of the corresponding equi-effective concentrations at other *p*H-levels are plotted against *p*H as the continuous line in Fig. 2. It is evident that greater concentrations of iodoacetate are needed to halve the respiration-rate at the higher *p*H levels. Thus at *p*H 3·5 the necessary concentration is 3×10^{-5} *M*, but at *p*H 7·5 the concentration needed to produce the same effect is one hundred times greater (3×10^{-3} *M*). It is therefore possible to find a concentration of inhibitor which will have no effect on respiration at one *p*H and yet will inhibit it completely at a lower *p*H.

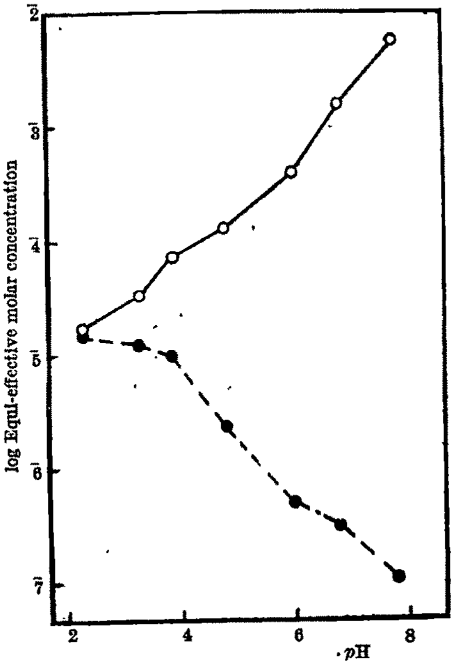

Fig. 2. Effect of *p*H on the concentration of sodium iodoacetate required to inhibit yeast respiration by 50 per cent. Full line, total concentration (A + HA); broken line, concentration of undissociated molecules (HA)

Iodoacetic acid is a weak acid with a *p*K of 3·1, and for any given concentration the amount of undissociated acid in the solution will decrease rapidly as the solution is made more alkaline according to the equation

$$pH = pK + \log \frac{[\text{dissociated acid, } (A')]}{[\text{undissociated, } (HA)]}.$$

To test the hypothesis that HA is the only active inhibiting agent[2,3], the amounts of HA at the equi-effective concentrations have been calculated and plotted for each *p*H (Fig. 2). It is seen that the concentration of HA does not remain the same (as it would if HA alone were active) but decreases at the higher *p*H-levels. The same is true for the effect of *p*H on the toxicity of many weak acids to a wide variety of plant and animal organisms[5]. The concentration of HA in the external solution is an important factor in determining the extent of inhibition, but it is clearly not the only one. The relationships shown in Fig. 2 have been interpreted[5] on the supposition that only HA penetrates into the cell but that local *p*H conditions inside the cell also determine the response by their influence on the extent of dissociation of the acid within the cell.

Experiments on the effect of sodium azide on yeast respiration have yielded curves similar to Figs. 1 and 2.

Our results emphasize the importance of control of *p*H during *in vivo* studies with inhibitors which are weak acids. The possibility is being examined that *p*H changes induced by carbon dioxide when yeast is fermenting in nitrogen in a closed Warburg vessel are instrumental in bringing about a form of the Lundsgaard 'differentiating' effect of iodoacetate[6]. We have, in fact, already shown that the inhibition of fermentation brought about by 10^{-3} *M* iodoacetate (which has no effect on respiration at the same initial *p*H—6·8) can be prevented if the carbon dioxide produced during treatment with the inhibitor is absorbed by potassium hydroxide.

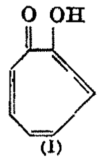
Synthesis of 3 : 4-Benztropolone

DEWAR[1] has interpreted the chemistry of the mould metabolite, stipitatic acid, and of colchiceine (the methyl ether of which is the alkaloid colchicine) by postulating that they are derived from the hypothetical *cyclo*heptatrienolone (I). This he termed 'tropolone', and he attributed to it quasi-aromatic character. This interesting suggestion, for which no tangible evidence was advanced[2], has acquired more plausibility from the recent demonstration of Haworth, Moore and Pauson[3] that purpurogallin is a trihydroxybenztropolone, as earlier suggested by Barltrop and Nicholson[4], and from the finding of Erdtman and Gripenberg[5] that the cedar-wood constituent γ-thujaplicin is an *iso*propyltropolone. Hitherto, a synthetic tropolone of established constitution has not been prepared, and the properties ascribed to such a structure have been based largely on speculation.

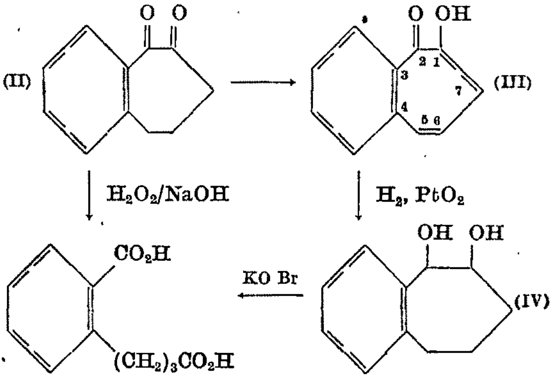
We have now synthesized one of the two possible benztropolones, namely, 3 : 4-benztropolone (III), and have made a preliminary survey of its properties. 2 : 3-Benz-1-suberone[6] was oxidized by selenium dioxide in boiling ethanol to 3 : 4-benzsuberan-1 : 2-dione (II), a deep yellow liquid, b.p. 128–132°/0·4 mm., which gave a mono-2 : 4-dinitrophenylhydrazone, m.p. 230–232° (found: C, 57·5; H, 3·95; N, 15·8. $C_{17}H_{14}O_5N_4$ requires C, 57·6; H, 4·0; N, 15·8 per cent) and a semicarbazone, m.p. 190–192°. The diketone (II) was dehydrogenated to 3 : 4-benztropolone (III) by bromine in acetic acid at 100°. The tropolone, obtained by this method in small yield, crystallized from *cyclo*hexane in pale yellow needles, m.p. 85–86° (found: C, 76·3, 77·0; H, 4·7, 4·6. *M* (Rast), 186. $C_{11}H_8O_2$ requires C, 76·7; H, 4·7 per cent. *M*, 172). Better results were obtained when the dehydrogenation was effected with 10 per cent palladized charcoal in boiling trichlorobenzene, under nitrogen (5 hours). The benztropolone was isolated in 10 per cent yield from the fraction of the products soluble in dilute sodium hydroxide solution. Two other products, not yet investigated, were also isolated. After the crude trichlorobenzene solution was diluted with benzene, shaking with sodium bicarbonate solution extracted a small amount of a compound which, after reprecipitation with acid, crystallized from light petroleum in yellow needles, m.p. 128–130°. Addition of sodium hydroxide solution to the benzene-trichlorobenzene liquors gave a buff-coloured neutral crystalline solid, m.p. 265–268°, the benztropolone being afterwards liberated by acidification of the alkaline liquors.

Benztropolone, of which purpurogallin is a trihydroxy derivative, had in most respects the chemical properties which would be expected from its structure and from the behaviour of natural products thought to be tropolone derivatives. Although, unexpectedly, not sufficiently acidic to undergo salt formation with sodium bicarbonate, it dissolved readily in sodium hydroxide solution. By fusion with 80 per cent potash at 180–185°, it was almost quantitatively converted into α-naphthoic acid.

The presence of a seven-membered ring, indicated by the method of synthesis, was confirmed by hydrogenation of benztropolone over Adams's catalyst to the diol (IV), which gave a yellow-green colour with Criegee's potassium tetramethylosmate reagent[7], was unaffected by alkaline hydrogen peroxide, but was oxidized by potassium hypobromite to γ-2-carboxyphenylbutyric acid (V), obtained also by oxidation of benzsuberone with 2 per cent nitric acid[8]. Benztropolone showed no carbonyl reactivity, but was hydrogenated over palladized charcoal to a resinous product which gave an immediate precipitate with 2 : 4-dinitrophenylhydrazine and was oxidized by alkaline hydrogen peroxide to the acid (V), as also was benzsuberandione (II). Microhydrogenation of benztropolone using palladium-black led to absorption of three molecules of hydrogen. Haworth, Moore and Pauson[3] recorded a similar behaviour in the hydrogenation of a methyltropolone, which they prepared by degradation of purpurogallin.



(I)



Benztropolone gave a brownish-red colour with ferric chloride, and dissolved in concentrated hydrochloric acid to a bright yellow solution. On dilution, the colour was destroyed and the benztropolone was precipitated. Benztropolone coupled with *p*-tolyldiazonium chloride to give a crimson precipitate.

Details of this work, which is being extended, will be published elsewhere.

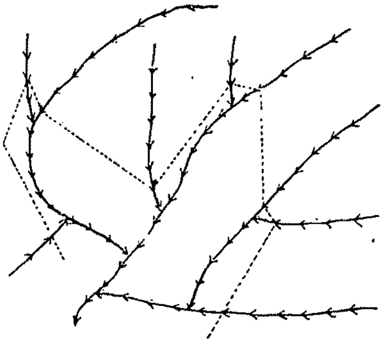
Amylopectin and Glycogen: Products of Irreversible and Reversible Synthesis

IT is assumed that the molecules of amylopectin and glycogen have a ramified structure, the glucose residues being united by α-glucosidic 1,4- or 1,6-linkages, the latter representing the branching points. By β, the 'degree of ramification', we shall denote the ratio between the number of 1,6-linkages and the total number of glucose residues. For amylopectin, β ~ 0·056; for glycogen, β ~ 0·09.

The biological synthesis of the polysaccharides is effected by two phosphorylases, one synthesizing 1,4-linkages, the other 1,6-linkages, the starting material being in both cases glucose-1-phosphate[1,2]. The first enzyme, studied by Hanes and others, when acting alone, synthesizes unbranched saccharides of the amylose type. This enzyme is called the '*P*-enzyme' by Haworth. Bernfeld, Meyer and their co-workers use the designation 'phosphorylase', whereas the enzyme synthesizing 1,6-linkages is termed 'isophosphorylase'. This enzyme seems, on the whole, to be identical with the '*Q*-enzyme' of Haworth and the 'branching factor' of Cori.



Part of a ramified molecule of the amylopectin–glycogen type. Parts outside dotted line are split off as maltose by β-amylase

When a polysaccharide is formed through the simultaneous action of both enzymes, one may imagine two extreme cases: one which has been emphasized by Bernfeld[3], Meyer[4] *et al.* is that of *reversible* synthesis, when the macromolecule is in contact with the enzymes for so long a time that its final state is one of equilibrium; the other extreme is a completely *irreversible* synthesis, where the growth of the molecules is so rapid that the reverse reaction is negligible.

We believe it possible to decide which of these two possibilities is most closely approached by studying the action of β-amylase on the macromolecules. This enzyme attacks only end chains, splitting off glucose units in pairs as maltose[5]. Now the fraction of the total number of glucose residues that can be split off by β-amylase is a quantity characteristic of the polysaccharide and can be experimentally determined; we shall denote it as ζ.

A few years ago[6], we derived a relation between ζ and β that should hold for the case of irreversible synthesis, supposing that the β-amylase cuts off as much as possible from the end chains without breaking any 1,6-links:

$$\zeta_{2(\mathrm{irr})} = 0\cdot 6557 - 1\cdot 4371\,\beta + 0\cdot 3151\,\beta^2 + 0\cdot 3154\,\beta^3 + \ldots \qquad (1)$$

Now we have derived the corresponding formula for the case of a macromolecule in its equilibrium state (reversible synthesis):

$$\zeta_{2(\mathrm{rev.})} = 0\cdot 5 - 1\cdot 25\,\beta + 0\cdot 625\,\beta^2 + 0\cdot 3125\,\beta^3 + \ldots \qquad (2)$$

In both cases it has been assumed that there is no serious steric hindrance, so the probabilities for the formation (or breaking) of 1,4- and 1,6-links have the same ratio in all parts of the molecule.

If these formulæ are applied to amylopectin with $\beta = 0\cdot 065$ we find $\zeta_{2(\mathrm{irr.})} = 0\cdot 58$ and $\zeta_{2(\mathrm{rev.})} = 0\cdot 43$, whereas the experimental values range between 0·55 and 0·62. On the other hand, for glycogen with $\beta = 0\cdot 09$ we find $\zeta_{2(\mathrm{irr.})} = 0\cdot 53$ and $\zeta_{2(\mathrm{rev.})} = 0\cdot 39$, whereas $\zeta_{\mathrm{exp}} = 0\cdot 35$–$0\cdot 45$. (A higher value which was occasionally found by Meyer may be due to degradation because of the rough pretreatment of the sample.)

Thus it appears that amylopectin is certainly not in an equilibrium state of the type assumed by Bernfeld and Meyer, although this might be approximately true for glycogen. Starch seems to be formed chiefly by a one-way process and is stored in the plant for a long time, whereas glycogen is formed as a reserve for short times of delivery and is continuously changing its amount in the animal (and yeast) organisms.

It seems possible that, under certain conditions, the organisms can form glycogen so rapidly that there is no time for equilibrium. In such samples of glycogen, the relation between β and ζ would deviate from (2) and tend toward (1).

Details of these calculations will be published in *Acta Chemica Scandinavica*.

Cephalopods from Local Waters at the University of Istanbul

Through the kindly co-operation of the British Council, I have been enabled to examine the local collection of Cephalopods of the University of Istanbul, which was sent to me by Prof. Curt Kosswig, of the University's Zoological Department.

It comprises eleven specimens, preserved in formalin solution:

Name	Overall length
Eledone moschata (Lamarck)	34 cm. 33 ,, 19 ,,
* *Sepietta neglecta ?* (Naef)	101 mm. 93 ,,
Sepia elegans (Orbigny)	158 mm.
Alloteuthis media (Linné)	205 mm. 185 ,, 181 ,, 179 ,,
† *Octopodoteuthis sicula* (Rüppell)	133 mm.

* Probably *S. neglecta*.

† Both fins had had about a third of the area farthest from the body cut off.

Of these five species, my regional records of the distribution of Cephalopods mention, as having been encountered in this region, only *Octopodoteuthis sicula* (Rüppell); locality, east of Rhodes.

NEW OPTICAL GLASSES

By R. KINGSLAKE and P. F. DePAOLIS
Kodak Research Laboratories, Rochester, New York

BEFORE 1880 the only types of optical glass available to lens designers were the flint-crown series, in which the addition of progressively increasing amounts of lead oxide led to a progressive increase in both refractive index and dispersive power, so that in effect there was a fixed relation between the dispersive power and refractive index of all available glasses (Fig. 1).

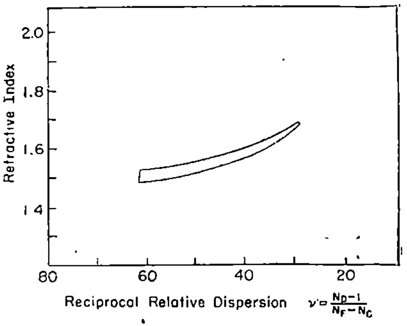

Fig. 1. Optical glasses (prior to 1880)

In order to achromatize any lens, the positive elements must be of lower dispersive power than the negative elements, and in those days this meant that the refractive index of the positive elements had to be low, and that of the negative elements high. This had two very adverse effects: on one hand, it tended to make the Petzval sum large, giving a strongly inward-curving field; and, on the other hand, it made the surfaces of the positive elements strong and those of the negative elements relatively weak. As the lens on the whole is positive, this resulted in considerable amounts of zonal spherical aberration, and also indirectly in large residuals of all the other aberrations.

For two reasons, then, a crown glass was needed with low dispersion and high refractive index, and also, if possible, a flint glass of high dispersion and low refractive index. The invention of barium crown glass in the 1880's by Abbe and Schott helped greatly to meet the first requirement, but the problem of the low-index flint was not solved at that time. (Incidentally, plastics, crystals and liquids mostly tend to have higher dispersion for their index than glasses, but these materials are generally undesirable for other reasons.)

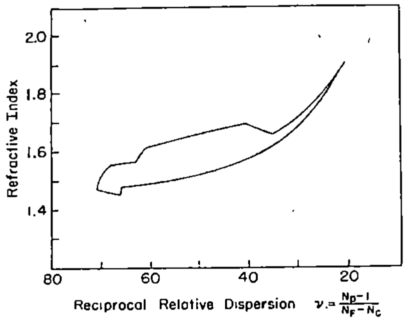

Fig. 2. Optical glasses (prior to 1934)

With the introduction of barium crown glass, many new types of photographic lens became possible, the first to be developed being cemented triplets of the 'Dagor' type, in which the three glasses are common crown, light flint, and dense barium crown in that order. Barium crown glass also greatly improved all lenses of the air-spaced type (the Cooke triplet and the 'Celor', for example) by weakening the surfaces of the crown elements and enabling the designer to shorten the lens without adversely affecting the Petzval sum. To be sure, some successful lenses of the meniscus type, for example, the 'Omnar', were designed without using barium crown; but these were the exceptions, and they did not become very popular.

The refractive index of barium crown glasses was raised slowly and steadily by Schott until the early 1930's (Fig. 2). At that time they introduced *SK*-16 and *SK*-18, which marked the upper limit of the ordinary barium–soda–lime silica types. These glasses are chemically unstable and present difficulties in lens manufacture because of their susceptibility to acid staining, and because of their brittleness.

Following the First World War, G. W. Morey, who had done work of great value in connexion with the production of optical glass for military purposes, discussed the advances which could be made in optical glasses with C. W. Frederick, chief of the lens designing bureau of the Eastman Kodak Company. Frederick suggested that what was wanted was a very high refractive index with low dispersive power and that even a small production on a laboratory scale would be useful. Morey undertook to study the optical properties of glasses in relation to chemical composition especially with a view to the production of high refractive index crown glasses. To this end all high atomic-number cations were chosen for systematic study in silicate, borate and phosphate glasses. Small melts of twenty to forty grams were made to indicate the field of glass formation. The more promising ones were repeated in larger melts of fifty to one hundred grams.

By 1933, the work had progressed to the point where silicon and phosphorus were discarded as glass-forming elements. Boric oxide had by now proved to be by far the best fluxing agent. Oxides of elements such as lanthanum and thorium found in the rare earths, and columbium, tantalum, tungsten, titanium, zirconium and strontium were used in major portions up to 80 per cent by weight, with or without the usual barium, zinc, magnesium and aluminium.

In 1934, samples of unusual glasses with characteristics n_D in the region of 1·85 and ν, the reciprocal relative dispersion, of 47·0 were in existence, and their properties well measured. About this time the work was expanded to a larger scale by the Kodak Research Laboratories. Under the direction of S. E. Sheppard, L. W. Eberlin and P. F. DePaolis made a systematic study of the solubility of the rare elements in boric acid and the limits of glass formation. The results of the combined work were revealed in patents by Morey[1] and by Eberlin and DePaolis[2].

Lanthanum is very soluble in boric acid, and its contribution to higher refractivity without increase of dispersion is remarkable. The oxides of tantalum, thorium and tungsten are soluble in the lanthanum borate base glass in amounts up to 35 per cent. These new borate glasses are very stable and fairly hard. They are harder than flints, suitably stable to the atmosphere, and amenable to optical shop practices of moulding, grinding and polishing.

Early in the development work it was found that the new rare-element borate glasses were extremely corrosive to all known pot refractories. A decision was therefore made to use platinum for the actual production of these glasses. This was justified on the basis that no platinum would be lost by contamination, and that the glass, once homogenized, could be poured in its entirety, free from striæ, into a single slab or into cast shapes without striæ, seed, bubbles or other defects usually attending a glass made in a refractory pot.

The first of the new glasses to be made had a refractive index of 1·7445 and a reciprocal relative dispersion of 45·8. The glass was slightly yellow, but further work established the origin of the yellow colour, and finally glasses were produced as colourless and homogeneous as any other ordinary optical glass.

Pilot-plant operation began in September 1937, and the first commercial glass was delivered in June 1939. Production increased rapidly, and more than 125,000 lb. of rare-element glass were produced during the Second World War (1942–45). Much of the success of the enterprise was due not only to the platinum equipment but also to the Kodak method of using all-electric heating and a small-pot, 'multi-pot–multi-stage' process.

Under sustained production conditions during the War, the yield of finished usable glass in a cast form was 95 per cent of the theoretical glass available in the batch.

Electric heating was retained in a plant that was erected during the War and operated from December 1942 to September 1945 on a continuous basis of approximately 5,000 lb. of finished glass a month. The process consisted of feeding thirty-two 10-lb. platinum-lined pots every twenty-four hours, starting one every three-quarters of an hour, and progressively moving these pots through the various stages of the glass-making process.

Since 1940 the types of these glasses in production have been extended, and at the present time the following seven types are being made:

	n_D	ν		n_D	ν
EK–110	1·69680	56·2	*EK*–330	1·75510	47·2
–210	1·73400	51·2	–450	1·80370	41·8
–310	1·74500	46·4	–448	1·88040	41·1
–320	1·74450	45·8			

All these glasses contain thorium, and in the case of folding cameras, in which the lens may rest for a long time in close proximity to film, the radioactivity of the thorium may be a disadvantage. A thorium-free equivalent of *EK*-320 is available.

The new glasses were first used in lens design in 1934; actual production of lenses began a few years later, and to-day many of the Eastman Kodak 'Ektar' lenses contain the high-index glass. The versatility of these glasses is evidenced by the large number of lens patents which specify such glasses.

After the transfer of the production of the new glasses to the factory, the Kodak Research Laboratories continued their study of optical glasses. Theoretical considerations by M. L. Huggins and K. H. Sun predicted the possibilities of further new glasses, and their predictions have proved correct. Of the glass systems of this type which were worked out by Sun, the most useful were flint glasses containing titanium oxide and using fluorine in addition to silica.

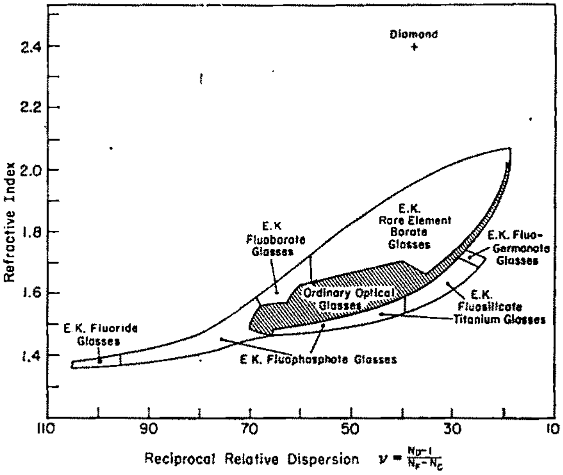

Fig. 3

These unusual glasses lie well below the ordinary flint line (Fig. 3). For a given index, the dispersion is appreciably greater than that of ordinary flints. In this sense the glasses may be termed super-flints. The best glasses lie in the region 45 per cent silica, 28 per cent titanium oxide, 27 per cent sodium fluoride, ranging in optical properties from n_D 1·65/ν29 to n_D 1·58/ν36·6. The glasses can be moulded, are very resistant to tarnish, and are easily fabricated by the usual optical methods.

The fluosilicate flints are almost as useful to the optical designer as the high-index glasses, since they extend the possible difference between crown and flint refractive index and between crown and flint dispersion. With these glasses, three-element lenses have been designed to give even better performance than the usual four-element types. K. H. Sun succeeded in producing novel mixtures in some twenty quite different glass fields, including fluo-borate, fluo-germanate[3] and fluo-phosphate systems.

A most interesting group of glasses suggested by Sun are those containing no oxides and composed entirely of fluorides. These glasses show the characteristic low refractive index and extremely low dispersion previously available only in fluoride minerals. The refractive index in most of the glasses is approximately 1·38–1·39 and the ν-value, 100. Moreover, the glasses are transparent to below 300 mμ in the ultra-violet and to 5 μ in the infra-red, so that they may be very useful in the making of instruments requiring optical transparency over a wide range of wave-lengths. Difficulties have been met in the production of these all-fluoride glasses, but it is possible that these difficulties may be overcome in the near future.

The extension of the frontiers of optical glass by this work is illustrated in Fig. 3. In this figure the range of optical glasses known before 1934 is shown shaded, while the larger area shows the glasses that can be made at the present time.

ACTIVITY COEFFICIENTS IN CONCENTRATED SOLUTIONS CONTAINING SEVERAL ELECTROLYTES

By Dr. E. GLUECKAUF

Atomic Energy Research Establishment, Harwell, Berks

In problems connected with concentrated solutions involving several electrolytes, it is necessary to have a knowledge of the activity coefficients of the separate salts. The determination of these activities in mixtures is usually a major experimental difficulty, and it is desirable to have a method for their calculation.

An important step in this direction was made by Guggenheim[1] in 1935, who derived the following equation for the activity coefficient $f^{\overset{X_1Y_1}{(X_2Y_2)}}$ of an electrolyte X_1Y_1, in the presence of another electrolyte X_2Y_2 (in different notation)

$$\log_{10} f^{\overset{X_1Y_1}{(X_2Y_2)}} = \frac{-0{\cdot}5\, x_1y_1}{(1 + I^{-1/2})} + \frac{x_1}{x_1 + y_1} \sum_X \lambda_{XY_1}[X] + \frac{y_1}{x_1 + y_1} \sum_Y \lambda_{X_1Y}[Y], \qquad (1)$$

where x and y are the ionic charges of X and Y, taken positive irrespective of sign, $[X]$, $[Y]$ are the molar concentrations of the ions, I is ionic strength $= \frac{1}{2}\Sigma(x^2[X] + y^2[Y])$, and λ_{XY} are constants. The subscripts 1 and 2 refer to the solutes X_1Y_1 and X_2Y_2, respectively.

As shown by Guggenheim, this equation with a suitable choice of constants gives excellent agreement with the observations up to an ionic strength of about 0·3 mol./l., but does not apply at higher concentrations.

An analysis of the properties of Guggenheim's equation shows that its application is restricted mainly by the assumption that the 'specific' part of the activity coefficient, represented by the λ terms, is linear in the concentrations.

However, if we assume that the λ's are not constant, but are functions of the ionic strength I, then a much wider range of application is possible. We can now eliminate the λ's from the known values of the activity coefficients of the pure solutes at this ionic strength. This leads to a relationship between the activity coefficients in a mixed solution $\left(f^{\overset{X_1Y_1}{(X_2Y_2)}}\right)$ and those of the pure solutes ($f^{X_1Y_1}$, $f^{X_2Y_2}$, etc.) at the total ionic strength I of the solution.

In the most interesting case, that of two ionic solutes with a common ion, we obtain the simple relationship :

$$\log_{10} f^{\overset{X_1Y}{(X_2Y)}} = \log_{10} f^{X_1Y} - \frac{[X_2]}{4I}\left[K_1 \log_{10} f^{X_1Y} - K_2 \log_{10} f^{X_2Y} - \frac{K_3}{(1 + I^{-1/2})}\right], \qquad (2)$$

where $K_1 = x_2(2x_2 - x_1 + y)$, $K_2 = x_1(x_2 + y)^2(x_1 + y)^{-1}$, $K_3 = \frac{1}{2}x_1x_2y(x_1 - x_2)^2(x_1 + y)^{-1}$, which permits the calculation of activity coefficients in mixed solutions if those of the pure solutes are known.

Similar equations can be obtained for solutions in which all the ions are different, and for more than two solutes ; and it should be emphasized that none of these equations contains freely adjustable constants.

Within the limits of the experimental error, equation 2 is obeyed equally well if used with the 'practical' activity coefficients (γ, for use with molalities), instead of the 'rational' ones (*f*, for use with mole-fractions).

The agreement of equation 2 with the experimental data is shown by the example of the activity coefficients of hydrochloric acid for mixtures of 0·01 *M* acid and barium chloride (0·03–3 molar ionic strength), representing the influence of a 2 : 1 electrolyte on the activity of a 1 : 1 electrolyte (see Table 1).

Table 1. Activity coefficients of hydrochloric acid in the presence of barium chloride at 25° C.

Ionic strength (molal) I	$\left[\gamma^{\mathrm{HCl}}_{(\mathrm{BaCl_2})}\right]_{m_{\mathrm{HCl}} = 0{\cdot}01}$		$\gamma\mathrm{HCl}$[2]	$\gamma\mathrm{BaCl_2}$[3]

The knowledge of activity coefficients in the presence of multiple solutes renders possible the application of mass-law equations to the solubilities of highly soluble electrolytes. Table 2 shows the constancy of the solubility product of barium chloride in the presence of hydrochloric acid, if use is made of the activity coefficients calculated by equation 2. It speaks for the correctness of the theory that the same solubility product (2·1 ± 0·05) is obtained if sodium chloride is used as a salting-out agent. These examples represent the influence of 1 : 1 electrolytes on the activity of a 2 : 1 salt.

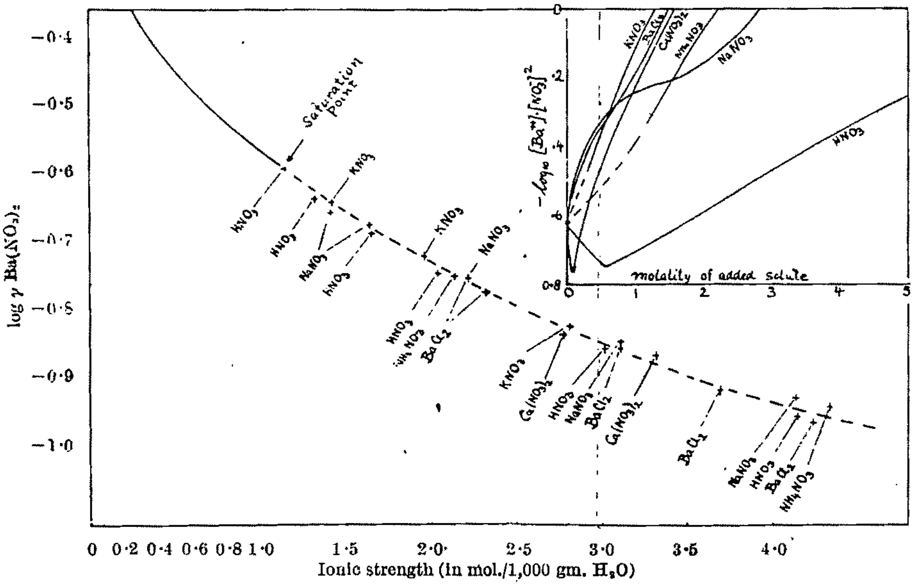
4·410	0·110	0·890	2·1
5·30	0·650	1·620	2·1

Another important application of the theory consists in the use of equation 2 for the calculation of activity coefficients of pure solutes in very greatly supersaturated solutions. After obtaining $\gamma^{\overset{X_1Y}{(X_2Y)}}$ from solubility products in the presence of a second solute, equation 2 can be solved for the activity coefficients of the pure solute (γ^{X_1Y}) at the ionic strengths of the mixed solutions, which are often greater than the saturation strength I of the pure salt X_1Y. As the activity coefficients so obtained must be independent of the nature of the second solute, agreement of the values of γ^{X_1Y} obtained from different combinations of solutes provides a very stringent test for the theory.

The accompanying diagram shows the activity coefficients of supersaturated solutions of pure barium nitrate calculated from its solubility data in the presence of barium chloride, potassium, sodium, calcium and ammonium nitrates, and nitric acid[5], all of which agree perfectly in spite of the greatly differing effect of these solutes on the solubility of barium nitrate. The method is particularly suitable for the calculation of activity coefficients in supersaturated solutions of salts of medium and low solubility, and it promises a considerable extension of our knowledge of activity coefficients by the application of equation (2) to the enormous mass of existing solubility data.



Activity coefficients of pure Ba(NO$_3$)$_2$ in supersaturated solutions calculated from solubilities in the presence of other solutes. Inset: solubility product of Ba(NO$_3$)$_2$ in mixed solutions

This extension of the theory to high concentrations does not, of course, improve other shortcomings which are inherent in the basic assumptions employed in the derivation of Guggenheim's equation, in particular the Brönsted[6] assumption: "that ions are 'specifically' influenced only by ions of opposite sign"; and in a number of cases equation (2) is only very imperfectly obeyed and apparently requires the introduction of an additional term. But in those cases where Brönsted's postulate is fulfilled, the new assumptions lead to equations which fully represent the 'specific' ion effects and cover the whole range up to and beyond the saturation concentrations.

Further details, including applications and critical discussion, will be published in due course.

RIVER-FLOW SURVEY AND RECORDS

A GEOPHYSICAL Discussion on the subject of "River-Flow Survey and Records" was held by the Royal Astronomical Society in its rooms at Burlington House, London, W.1, on January 28, 1949, with Sir Roger Hetherington in the chair.

Mr. H. J. F. Gourley opened the discussion. He said that rivers have always played a very important part in the life of the community. In Great Britain the upland tributaries, which are free of contamination, form the chief source of water supply. The larger tributaries and main streams determine the sites of villages and towns and provide the necessary water for industrial development. Thus, quite apart from its scientific interest, an accurate knowledge of river flow is of great importance. The minimum flow is of special significance, for it determines the amount of water available for industrial processes such as cooling, and limits the amount of effluent which may be discharged without excessive contamination. In areas liable to flooding, the maximum flow is also of obvious importance.

The Land Drainage Act of 1930 made no provision for Government grants towards the expenses involved in gauging the flow in British rivers, but the River Boards Act (1947) has now remedied this. It also empowers the Ministry of Health to make recommendations to the various river boards. At present, the Thames is the only river in Great Britain for which day-to-day records exist. In other cases, the Meteorological Office provides good estimates of the rainfall, but lack of knowledge of evaporation and storage makes estimates of run-off somewhat uncertain. They form the principal data from which the engineer can work, and provide a valuable means of obtaining advance information of floods. Nevertheless, they cannot replace accurate gauging, and it is to be hoped that the Ministry of Health will, in future, give every encouragement to this type of work.

Dr. J. Glasspoole, of the Meteorological Office, described how estimates of river flow can be made from rainfall data. Great Britain is remarkably well equipped with rain gauges, and analysis of the records from these has led to a good understanding of the effect of topography on the distribution of rainfall. The actual precipitation over a given basin can usually be determined to within a few per cent, but to derive the run-off in the river requires, in addition, a knowledge of storage and evaporation. Neither is accurately known, but, even so, the correlation coefficient between rainfall and run-off is 0·9, indicating that 80 per cent of the observed fluctuations in river flow can be accounted for by precipitation. To obtain better results there must be close collaboration between meteorology and hydrology. Further information is required on snowfall and its rate of melting. The factors affecting evaporation are very complex, and although considerable work has been done on this problem, it seems unlikely that reliable estimates can be made at present. River flow records are therefore an essential factor, not only for determining the actual run-off but also as a means of finding out about storage and evaporation.

The technical problems involved in gauging the flow of a river were described by Capt. W. N. McClean. When measurements are required, it is seldom practical to construct a special weir or flume, and in these circumstances the best method is to select a stable reach and measure the flow through this with a current meter. Readings must be taken over the whole cross-section area and integrated to give the total flow. Means of locating the current meter quickly and accurately are of great practical importance, and some details were given of a suitable cableway which could be stretched across the river and from which the meter could be lowered at any selected point to the required depth. Measurements of flow have been made for several rivers in Scotland, and fifteen years of continuous records for five of these have been published in tabular form by Capt. McClean. But much more work is required. Water is a very valuable asset, more valuable even than coal, and yet there is no Inland Water Survey in Great Britain. Recent flood damage on the main railway line north of Berwick might well have been averted had there been adequate rainfall and run-off data available to the engineers who designed the line. The silting up of estuaries and the design of hydro-electric schemes are also problems for which river flow records are essential. There is a great need for an organised survey, calling for close co-operation between the Ministry of Health, the Ordnance Survey, the Meteorological Office, the Ministry of Agriculture and Fisheries, and the various river boards and water supply authorities.

Mr. W. Allard, of the Ministry of Health, explained how it is that in the past so little attention has been given in Great Britain to river flow recording. Water supplies are abundant, and there has been no difficulty in meeting the small requirements. In the case of the Thames, very complete data exist; records of the flow at Teddington weir go back as far as 1883. In due course, no doubt, the various river boards will put forward their own suggestions for surveys. Both graphical and tabular methods of recording river flow were considered by Mr. Allard, and it was shown how such data could be used to predict floods and to estimate the changes in flow which would result from a given precipitation.

A lively discussion followed in which all agreed that a more complete survey of river flow is most desirable. Mr. E. Gold pointed out that the average flow gave little useful information and that it was important to know the fluctuations. The Zambesi Falls were given as an example. Here the average annual ratio of maximum to minimum run-off is about 30 to 1, which makes the falls almost useless as a source of hydro-electric power. There were, however, considerable differences of opinion as to the best method of making the measurements. Mr. R. V. Stock, of the Thames Conservancy, described the system of weirs in use at Teddington and explained how it was intended to extend and improve them, to obtain greater accuracy especially at times of minimum flow. Sir Claud Inglis stated that weirs and throated flumes gave the best accuracy, but Capt. McClean maintained that the propeller type of current meter could give excellent results, and, further, could be used on any stable reach of a river without the need for special constructional work. Mr. J. F. Francis, however, doubted if the latter could provide measurements accurate to better than a few per cent; for very low rates of flow, propeller gauges are not reliable.

COMMONWEALTH COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

THE twenty-first annual report of the Council for Scientific and Industrial Research*, Commonwealth of Australia, covering the year ended June 30, 1947, states that consideration was being given to the establishment of two divisions for textile research, one for fundamental work on the chemistry and physics of the wool fibre, and the other to concentrate on the technology of the spinning and utilization of wool. It was hoped at an early stage to commence some work on the degreasing of wool with hydrocarbon solvents as distinct from the normal soap and water scours, and that university research workers will be encouraged to study the fundamental structure and properties of the wool fibre. Other new developments include the appointment of an officer to take charge of the Meteorological Physics Section, where work for a few years will centre on the detailed examination of the atmospheric conditions over a small area. Arrangements have also been made by the Council for a small co-operative section of metallurgy to be accommodated at the University of Melbourne. The initial programme of work will include studies of the properties of metals at high temperatures, the preparation of metal compacts from metal powders and the application of X-rays to studies of metals and alloys. A small team of engineers and chemists has been collected to study the utilization of atomic energy for industrial purposes; this team will work at Harwell, England, and arrangements have also been made for a co-operative programme of research in nuclear physics at the University of Melbourne. A Tracer Element Research Committee has been appointed to advise the Council in work with radioactive isotopes.

Reports have indicated that much of the trouble existing in Australian coal mines could be alleviated by applying established methods of dust prevention, and it has also been recommended that a more detailed survey should be made of the conditions in the mines and into the best means of measuring dust concentrations; and as a result of the visit of the late Prof. T. David Jones, the Council has established a Coal Dust Research Advisory Committee to advise on a programme of research. Attention was also given to the scientific aspects of plans for the Australian Expedition to the Antarctic during 1947–48. The Expedition was expected to pay particular attention to geophysical problems, including meteorology, the earth's magnetism, cosmic rays and, possibly, radio propagation. The scheme for overseas training is now in full operation, and twenty-five officers were abroad during 1946–47. Special emphasis is also laid in the report on the increasing help given to the Council by the universities.

---

* Commonwealth of Australia. Twenty-first Annual Report of the Council for Scientific and Industrial Research for the year ended 30th June, 1947. Pp. 139. (Canberra: Commonwealth Government Printer, 1948.) 6s.

The work of the Division of Plant Industry has continued on similar lines to those described in the previous report. Work on weeds has now been divided into two sub-sections—physiology and ecology. The former is concerned with the physiology and biochemistry of plants as related to the penetration and translocation of plant poisons and with the development of more efficient herbicides. The ecology sub-section is concerned with the determination of the ecological factors pertaining to the invasion and establishment of weeds, particularly in grassland, including the testing of herbicides in the field. The search for native plants as sources of supply for medicinal drugs and insecticides has continued, and a list of publications of the Division during the year is appended.

In the Division of Economic Entomology, the most important development during the year has been the change in the cattle-tick situation as a result of the thorough establishment during the year of the practicability and efficacy of using a water-miscible preparation of D.D.T. in dipping-vats. This preparation was developed in June 1946 by a team of the Division's workers in Queensland.

Much of the work of the Division on the chemical control of insect pests has been concerned with the use of D.D.T. and 'Gammexane', very promising results being obtained in Western Australia with these dusts against the red-legged earth mite. Biological-control investigations form a major part of the Division's activities and have progressed very satisfactorily. The introduced insect enemies of St. John's wort continue to clear land of the weed at an undiminished rate, and new projects which have been initiated include: the introduction and breeding of parasites of the cabbage moth; a biological study of the Dawson River sandfly; laboratory studies of factors controlling the levels of insect populations; and ecological studies of cockchafer beetles. A meeting of the Codling Moth Committee, at which all the State Departments of Agriculture were represented, as well as the Waite Agricultural Research Institute and the Division itself, was convened at Canberra in May 1947. The Division of Animal Health and Production continued its work on the usual lines, but difficulties arose in all branches of the work, mainly through the shortage of accommodation, supplies and staff. Plans for the development of the work on animal breeding, genetics and animal production, however, were advanced during the year, and in the Department of Biochemistry and General Nutrition increased attention has been given to research on more fundamental spheres of the nutritional physiology of sheep.

Soils investigations have again largely been concerned with areas intended for land-settlement schemes for returned servicemen and especially those areas in which a major change in the use of the land is contemplated, such as from dry farming to irrigation or from native vegetation to seeded pastures. Studies on soils associated with toxæmic jaundice of sheep have continued, while, besides the investigation of methods of determining phosphates in soil, a new method has been developed for the determination of molybdenum in plant materials. The principles underlying retention of water in soils have been further studied, and investigations, which were commenced for the Building Materials Section, on soil as a foundation material for houses, have continued.

Considerable progress is reported in forest products investigations, and fundamental studies on wood chemistry and pulp and paper problems have been continued in co-operation with the pulp and paper industry. With the object of accumulating the requisite background and information for an examination of saw-mill design, saw-mill studies have been carried out in Queensland in co-operation with the Queensland Sub-Department of Forestry and the Queensland Timber Stabilization Board, and in Victoria with the Victorian Saw-millers' Association. Work on the thermal conductivity of wood and on creep in initially green beams has continued, and an attempt was made to standardize the methods of electrical strain-gauge manufacture and to improve the technique of the manufacturing process. Other work, on the seasoning and the preservation of timber, particularly the preservative treatment of the tree-wood of eucalypts of lower durability for railway sleepers, has yielded important results; and work on the latter problem has indicated that a study of the diffusion of electrolytes into timber offers a possible approach to fundamental aspects of the physical chemistry of wood.

Besides the changes in food-preservation investigations recorded in last year's report, the Physics and Transport Section has commenced a major investigation of the transport of frozen produce in insulated railway vans, and more attention has been given to several long-term chemical and biological studies. Investigations of the volatile organic substances from Granny Smith apples, the mechanism of catalytic oxidation of ascorbic acid by metals, and the stability of dehydroascorbic acid were carried out; the anti-bacterial properties of cationic detergents, the maturation or tenderizing of beef, the damage to beef casings by *Dermestes vulpinus*, and skin coatings for apples also received attention; and the programmes of work on fruit canning and the dehydration of fruit and vegetables have been carried out. Further progress is reported in the development of the schedule of fisheries research, but, although all sections of the freshwater, estuaries and inshore programme were extended, deep-sea investigations on pelagic fish occurrences with the motor vessel *Warren* could not be resumed until January 1947. During 1947–48 it was hoped to extend the exploratory and survey work to tropical waters. An exceptionally interesting report records progress in survey work or investigations on pilchards, sprats, anchovies, whitebait, trawl fish, Australian salmon, mullet, shellfish, marine crayfish, etc., as well as in hydrological and seaweed investigations.

The Division of Metrology reports increased attention to the maintenance of standards and associated research, including the measurement both of mass and length and associated quantities. The Division of Electrotechnology has likewise been able to give more attention to fundamental research and is developing its research activities mainly on the electrical and magnetic properties of materials and mathematical instruments; work in the former direction has been so far confined to dielectrics, including the treatment of glass, steatite and other siliceous compounds to improve their electrical insulation resistance to moist atmospheric conditions, and the relation between molecular structure and dielectric properties of insulating materials. A more balanced programme of work has been possible in the Division of Physics, where about half the time of the scientific staff is now available for research. Three new major projects have been commenced: the setting up of equipment for research at very low temperatures; laboratory investigations on the artificial production of rain; and the absolute measurement of ultra-violet spectral energy distributions with the view of determining solar energy distributions. Advice has been given on special devices for temperature measurement and control, and work is also reported on the physical phenomena involved in the formation of ice crystals, on the physics of solids, photometric standards and evaporation plant.

In the Division of Aeronautics greater concentration on the fundamental and long-term projects was also possible, and, while the Australian Council for Aeronautics was disbanded during the year and will be replaced by a research committee, the relations of the Division with the Universities of Sydney and of Melbourne have already been strengthened. Reference is made in the report to work on such varying topics as the stability of plates and shells, the life of aircraft and effect of temperature on their strength, fatigue of metals, properties of alloys, powder metallurgy, high-speed subsonic and transsonic flow, the use of suction to increase efficiency at moderate speeds, piston-ring lubrication and the elimination of wear due to dust. In the Division of Industrial Chemistry progress is reported in the inauguration of ceramic research, but the work of the Biochemistry and Organic Sections has been handicapped by absence of proper accommodation. Construction of a new building was expected, and in the meantime the work of the Division has continued much on the lines described in the last report. Collaboration with the Division of Physics in studies of the structure of the wool fibre continued, and theoretical and experimental investigations have been conducted on luminescent materials used in the lamp and radio-valve industries.

Work in the Division of Radiophysics has led to fuller knowledge of the radiations emitted at radio frequencies from the sun and in the universe. This Division has opened up a promising new avenue of research which should provide basic information on the physics of cloud formation and may lead to the practical possibility of stimulating rainfall by artificial means and to the completion and successful demonstration of new radar aids to civil aviation. The Section of Tribophysics has confined its work on lubrication mainly to a study of the frictional properties of molecular layers of lubricating substances. Wear is being studied by mechanical and metallurgical methods as well as with a radioactive tracer technique. The group dealing with the mechanical properties of metals is endeavouring to obtain a better knowledge of the properties of metallic crystals and the way the mechanical properties in particular are changed by heat. The work on explosives has already made substantial contributions to knowledge of the mechanism of explosion in liquids.

The work of both the Building Materials Research Laboratory and of the Flax Research Laboratory has been seriously handicapped by limited accommodation and, for the former, by the further difficulty in recruiting staff. Nevertheless, weathering studies have proceeded, as well as investigations on concrete, masonry, surfacing materials, building boards and insulating materials, adhesives, etc. The Dairy Research Section, which has now incorporated the Dairy Section of the Division of Industrial Chemistry, has studied the advantage of eliminating the washing of buttermilk from the butter granules, weed taint in butter and the utilization of the solids of skim milk. Among miscellaneous investigations is included an account of the study of the growth and rubber content of the guayule plant under Australian conditions at the Waite Institute, Adelaide, which was commenced five years ago and which is now approaching a stage when interesting and important comparisons will be possible.

DESIGN OF RADIO AERIALS

THE number and diversity of the radio communication services now in operation in an overcrowded spectrum demands that the utmost efficiency must be obtained in the design and operation of both sending and receiving stations. At the transmitting end it is necessary that the minimum power be used and the radiation be concentrated in the desired direction; while at the receiving end aerials of high directivity are also required in order to ensure that the incoming field produces a satisfactory signal, to the exclusion of any unwanted noise or radiation coming from some other direction.

Thus, in point-to-point communication it is desirable to make the two aerial systems as directional as possible. At fixed frequencies high directivity can be obtained by using aerial-array, long-wire, or rhombic aerial systems, but if several frequencies are to be used with the same system, aerial arrays are unsuitable.

A report which will help the engineer in designing a radio communication service for maximum efficiency has recently been published*. It presents in a convenient form a generalized analytical method of calculating the polar diagram of any long-wire aerial system over a wide band of frequencies. The analysis is also applied to the determination of the polar diagrams of horizontal rhombic aerials.

The object of the paper is to describe the simple theory of long-wire aerials in such a manner that the physical principles involved may be readily understood and the results applied to special or new systems. Methods are developed whereby the probable polar diagrams of long-wire systems may be rapidly estimated for a wide range of operating frequencies or for changes in other parameters. These may be used to reduce the work involved in calculating an accurate polar diagram in which allowance is made for second-order effects; the technique is to sketch the approximate polar diagram given by the simplest theory applicable to the problem, and then to calculate the exact values for the important maxima and minima. The results of the analysis are presented in the form of design charts with such information as: families of contour curves of constant directivity against angle of azimuth and elevation for a constant frequency; or as curves giving the position and relative amplitude of the main lobes in the vertical plane through the aerial against angle of elevation and frequency. A similar treatment is

* Department of Scientific and Industrial Research. Radio Research Special Report No. 16. A Method of Determining the Polar Diagrams of Long-Wire and Horizontal Rhombic Aerials. By W. R. Piggott. Pp. iv+39. (London: H.M. Stationery Office, 1948.) 9*d*. net.

followed for the case of the horizontal rhombic aerial. The methods described may easily be applied to other types of long-wire aerial, or to linear arrays of aerials having constant input amplitude in each aerial, and constant relative phase shift between aerials.

The approximate methods described are particularly useful when calculating coverage areas obtained by reflexion from the E- or F-regions in the ionosphere. It is unnecessary to know the polar diagram shapes exactly as the movements of the reflecting layers from day to day cause appreciable changes in the exact zone covered, and the approximate results are therefore of great practical value.

MIDDLE DEVONIAN OSTEOLEPID FISHES OF SCOTLAND

FOR more than a century, since the days of the pioneer workers on the Old Red Sandstone, the osteolepid fishes have proved a source of difficulty to vertebrate palæontologists, and even more so to stratigraphers. One has only to glance at the restorations of the whole fishes on p. 103 of Dr. E. Jarvik's recent monograph* and of the heads of the various forms dealt with to understand why. For so uniform in general are their characters that unless the bodies are well enough preserved to show the details and the disposition of the fins it is almost impossible to be certain even of the genus, and if the skull-roof is not clearly shown then the species is more often than not in doubt; and finely preserved bodies and clearly detailed heads are not so very common in these ancient strata, laid down 300 million years ago. The long historical accounts of each of the three genera and seven species described clearly indicate the confusion that has arisen in the past, and even Dr. Jarvik's exhaustive investigations leave some loose ends for future workers to tie up.

The group is a most important one, anatomically by reason of its close relationship to the fishes from which the land vertebrates sprang, and geologically as one of the dominant types present in these complicated stratal series. This fine volume is a worthy addition to the classical series of exhaustive and luxuriant memoirs on the early fossil Vertebrata that have issued in an endless stream from the Stockholm school under the guiding genius of Prof. Stensiö, and in it Dr. Jarvik gives a full account of the external anatomy of this difficult group and of its systematics, which will long remain a standard on the subject, even if one cannot accept all his conclusions. The long-fought controversy regarding the identity of the external bones of the skull, upon which their nomenclature, of course, depends, is again gone over, and Dr. Jarvik has decided definitely in favour of the 'Fusionist' or Swedish school of thought as against the 'Replacement' or Anglo-American school. Yet Dr. Jarvik himself makes some admissions and expresses some doubts, though of a minor nature, as to the completely universal application of his conclusions—much depends on analogies with similar structures in modern fishes; and the evidence of analogies is not always conclusive, especially as no living fishes are closely related to the archaic osteolepids. We may perhaps be pardoned, therefore, for hesitating to believe that the final word on the subject has been written.

The stratigraphical results are important, but before full advantage can be taken much new collecting would be necessary—and that, unfortunately will not be possible in all cases. The early collectors of fossils, and not only of Old Red fishes, either did not appreciate the need for exact localization, or deliberately omitted details from labels in order to keep to themselves the whereabouts of 'rich strikes', and so the source of many of the specimens is uncertain.

Finally, Dr. Jarvik is not quite clear on the rules of systematic nomenclature. In naming a group of the genus *Osteolepis* which Pander had apparently wrongly referred to Agassiz's uncertain species *O. microlepidotus*, he calls it *O. panderi* (Pander). Pander may have properly defined this group for the first time, but a name cannot be attributed to a man who died decades before it was invented (and anyway, why in brackets? Pander at least put it in the right genus); and the species, if valid, must be known as *Osteolepis panderi* Jarvik. This is a minor point, and it is, perhaps, ungrateful to mention it in reviewing a work of this importance; but whatever one may think about the subject of systematic nomenclature, it has a proper function and should be used correctly, especially when the author makes some show of taking the matter seriously by quoting rules and opinions, and particularly in a volume that is likely to remain the standard work of reference on the subject for some time to come. Errol White

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 14

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Mr. O. G. S. Crawford: "Some Mediaeval Theories about the Nile Basin".

University of London (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m.—Mr. T. G. Ridling: "The Translation of Technical Education".*

Chemical Society, Eire Section (joint meeting with the University College of Dublin Chemical Society and the Werner Society, in the Department of Chemistry, Trinity College, Dublin), at 7.45 p.m.—Prof. T. S. Wheeler: "The Development of the Periodic Table".

Tuesday, March 15

Chemical Society, Leeds Section (joint meeting with the University Chemical Society, in the Chemistry Lecture Theatre, The University, Leeds), at 5 p.m.—Display of Scientific Films; at 6.30 p.m.—Prof. E. L. Hirst, F.R.S.: "Structural Relationships amongst the Polysaccharides".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. H. J. Emeléus, F.R.S.: "Some Recent Advances in Radiochemistry". (Further Lectures on March 22 and March 29.)

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. G. P. Tyrer: "Outline of the History and Development of the Beet Sugar Industry in Great Britain".

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.30 p.m.—Prof. K. de B. Codrington: "Cultivated Cereals and Early Civilizations".* (Further Lecture on March 22.)

Society of Chemical Industry, Plastics Group (at the Royal Society of Tropical Medicine, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Mr. D. L. Clarkson and Mr. N. D. MacLeod: "Polyvinyl Chloride Pastes".

Institution of the Rubber Industry, London and District Section (at Caxton Hall, Caxton Street, London, S.W.1), at 7 p.m.—Mr. W. H. Reece: "Continuous Vulcanisation Processes".

Institution of the Rubber Industry, Scottish Section (at the Institution of Engineers and Shipbuilders, 39 Elmbank Crescent, Glasgow), at 7.30 p.m.—Annual General Meeting; Dr. W. J. S. Naunton and Mr. J. M. Buist: "Rubber to Metal Bonding".

Wednesday, March 16

Association of Applied Biologists (in the large Physics Theatre, Imperial College of Science and Technology, Imperial Institute Road (morning session), and the Metallurgy Lecture Theatre, Prince Consort Road (afternoon session), London, S.W.7), at 11.45 a.m. and 2.15 p.m.—Papers on "Growth-promoting Substances in Agriculture and Horticulture".

Royal Institute of Chemistry, London and S.E. Counties Section (joint meeting with the London Branch of the Institute of Physics, at the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m.—Prof. F. J. M. Stratton, F.R.S., and Mr. F. Hoyle: "The Chemistry and Physics of Hot Stars".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Charles Reid and Dr. William Reid: "The Reconstruction of the British Mining Industry" (Cadman Memorial Lecture).

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Discussion on "Meteorology in Agriculture" (to be opened by Dr. H. L. Penman and Mr. R. W. Gloyne).*

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Prof. Gerhard Tintner: "Foundations of Probability and Statistical Inference".

Manchester Literary and Philosophical Society, Social Philosophy Section (at the Portico Library, Mosley Street, Manchester), at 5.30 p.m.—Mr. Michael Oakeshott: "What is Political Philosophy ?"*

Royal Microscopical Society (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. I. M. Dawson: "The Electron Microscopy of Animal Viruses".

Royal Statistical Society, North-Eastern Group of the Industrial Applications Section (at the Chemical Industries Club, 18 Lovain Place, Newcastle-upon-Tyne), at 6.30 p.m.—Mr. W. J. Jennett: "The Integration of Elementary and More Advanced Statistical Methods in the Control of Processes".

Thursday, March 17

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. M. Bruckshaw: "Geophysics and Economic Geology".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. H. Zassenhaus: "The Theory of Space Groups".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Lawrence Bragg, F.R.S.: "The Physics of the Solid State". (Further Lectures on March 24, March 31 and April 7.)

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. J. Mullin and Mr. C. G. I. Gardiner: "The Design of Propellers".

Society of Chemical Industry, Road and Building Materials Group (joint meeting with the London Group of the Industrial Applications Section of the Royal Statistical Society, at Gas Industry House, 1 Grosvenor Place, London, S.W.1), at 6 p.m.—Mr. F. Garwood: "The Use of Statistical Methods in Road Research Problems".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.15 p.m.—Discussion on "Aspects of Heterogeneous Catalysis" (arranged by Dr. R. Holroyd).

Chemical Society, Edinburgh Section (joint meeting with the Royal Institute of Chemistry and the Society of Chemical Industry, in the North British Station Hotel, Edinburgh), at 7.30 p.m.—Dr. F. N. Woodward: "Recent Trends in the Industrial Utilization of Agricultural Products in North America".

British Institute of Radiology (at 32 Welbeck Street, London, W.1), at 8 p.m.—Mackenzie Davidson Memorial Lecture.

Friday, March 18

Physical Society, Acoustics Group (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Annual General Meeting; at 3 p.m.—Ir. E. W. van Heuven: "The Acoustics of Bells".

Chemical Society, Birmingham Section (joint meeting with the University Chemical Society, in the Main Chemistry Lecture Theatre, The University, Birmingham), at 4.30 p.m.—Dr. F. G. Mann, F.R.S.: "Some Aspects of Stereochemistry".

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5 p.m.—Mr. K. A. B. Gilfillan: "The Use of Radar Beacons".

Imperial College of Science and Technology (at the City and Guilds College, South Kensington, London, S.W.7), at 5.30 p.m.—Dr. Jean Laurent: "Reduced Scale Models in Hydraulics and in the Construction of Sea Ports—some Novel Observations".

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 6.30 p.m.—Annual General Meeting; at 7 p.m.—Dr. W. F. Berg: "Recent Views on the Theory of the Photographic Latent Image".

Society of Instrument Technology, Midland Section (at the Arden Hotel, New Street, Birmingham), at 7 p.m.—Mr. W. Wilson: "The Microscope in Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Kathleen Lonsdale, F.R.S.: "Neutron Diffraction by Crystals".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Analyst, Mineral Nutrition of Plants and Soils—The Secretary, Long Ashton Research Station, Long Ashton, Bristol (March 19).

Lecturer in Rayon Technology, and a Senior Assistant with suitable qualifications in economics, industrial administration and management, in the Bradford Technical College—The Director of Education, Town Hall, Bradford (March 19).

Principal of the Municipal Technical College—The Chief Education Officer, West House, Halifax (March 19).

Research Assistant in the Department of Anæsthetics in the Medical School—The Registrar, King's College, Newcastle-upon-Tyne (March 19).

Senior Fellowships (2) and Junior Fellowships (3) in the Research Laboratory for Nuclear Physics, Lahore, Pakistan—The Educational Attaché, High Commissioner for Pakistan, 14 Fitzhardinge Street, London, W.1 (March 21).

Lecturer in Bacteriology and Research Assistant—The Secretary, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (March 21).

Warden (who will be the Chief Administrative Officer) of the Liverpool Institute of Education—Dr. J. F. Mountford, The University, Liverpool (March 21).

Chair of Engineering—The Registrar, The University, Nottingham (March 22).

Assistant Keeper in the Department of Natural History, and a Keeper of the proposed Technical and Science Museum—The Director, City Museum and Art Gallery, Birmingham 3 (March 23).

Laboratory Workshop Officer in Electrical Engineering, a Laboratory Workshop Officer in Radar and Telecommunications, and an Officer-in-Charge of Mechanical Engineering Workshops, at the Military College of Science, Shrivenham, Swindon—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, S.W.1, quoting No. 2438 (March 24).

Deputy Director, an Engineering Geologist, and Field Geologists, in the Burma Geological Department—The Burmese Embassy, 19a Charles Street, London, W.1, quoting No. 3AP49 (March 25).

Principal Scientific Officer (microbiologist, pathologist or physiologist with research experience), a Senior Scientific Officer (physicist with a special knowledge of electronics and research experience), and a Senior Scientific Officer (chemist with research or works experience), in the War Office—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2454 (March 26).

Scientific Officers (with a good honours degree in a biological science or in chemistry), and Experimental Officers (with a minimum of 3 years' laboratory experience in pathology, bacteriology, biochemistry or physiology), at Ministry of Supply Research and Development Establishment in Wilts and Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.550/48 (March 26).

University Lecturers in Agricultural Botany, Farm Machinery, and the History and Economics of Agriculture, and a University Demonstrator in Agriculture—The Secretary, School of Agriculture, Cambridge (March 31).

Physicist in the Magnetic Survey, Christchurch—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (April 1).

Beit Fellowships for Scientific Research—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7 (April 2).

Senior Technician and a Technician—The Dean, Postgraduate Medical School of London, Ducane Road, London, W.12 (April 12).

Senior Lecturer (Grade I) in the Department of Physics—The Registrar, The University, Liverpool (May 1).

Lecturer in Mathematical Statistics, and an Assistant Lecturer in Applied Mathematics—The Registrar, The University, Liverpool (May 1).

Beit Memorial Fellowships for Medical Research—The Secretary, Beit Memorial Fellowships for Medical Research, Lister Institute, Chelsea Bridge Road, London, S.W.1 (May 14).

Assistant Water Engineer in the Colonial Geological Survey Service, Cyprus—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27079/35.

Plant Geneticist in the Agricultural Department, Government of Tanganyika—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Economic Botanist in the Department of Agriculture, British Guiana—The Director of Recruitment, Colonial Service, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Senior Lecturer in the Department of Aircraft Propulsion—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks.

Lecturer in Mathematics—The Principal, Guildford Technical College, Stoke Park, Guildford.

Senior Assistant in the Department of Civil and Mechanical Engineering—The Principal, Technical College, Queen Street South, Huddersfield.

Technical Assistant in the Research Physics Department—The Secretary, South Manchester Hospital Management Committee, Christie Hospital and Holt Radium Institute, Manchester 20.

Lecturer in Biology—The Principal, Medway Technical College, Gillingham, Kent.

Physicist in the Biochemical and Endocrinological Research Department, and a Senior Biochemist—The Medical Superintendent, Bristol Mental Hospitals, Barrow Hospital, Barrow Gurney, near Bristol.

Senior Scientific Officers and Scientific Officers in Government Departments throughout Great Britain—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2351.

Mathematician (with interest both in mathematical solution of engineering and physical problems and in statistical treatment of research data) in the Scientific Research Department, Derby—The Scientific Research Manager, Railway Executive, London Midland Region, Euston Station, London, N.W.1.

Research Physicist—The Director of Research, British Scientific Instrument Research Association, Sira, Southill, Chislehurst, Kent.

Senior Laboratory Technician for Department of Neuropathology—The Secretary, Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5.

Lecturer in Anatomy—The Secretary, The University, Aberdeen.

SCIENTIFIC AND CULTURAL CO-OPERATION

ONE factor which has hindered constructive discussion in Great Britain of the United Nations Educational, Scientific and Cultural Organisation is the comparative inaccessibility of many of the official documents. Although reports of the Beirut Conference last year do not yet appear to be available, the publication of Dr. Julian Huxley's second report as director-general (see p. 457), covering the activities of the Organisation during 1948, has made possible a fresh appreciation of the value and prospects of the Organisation. Together with a debate in the House of Lords on January 26, it serves to correct some ill-informed criticisms, and indicates both some of the achievements to the credit of Unesco and some weaknesses that require attention.

Reference was made to this report in the House of Lords debate, notably by the Bishop of Chichester; but this reference gave no idea of the value and scope of Dr. Huxley's valedictory message. Even more valuable than his detailed account of activities, which on some points of presentation is open to criticism, is the general survey which precedes the detailed report. In this survey Dr. Huxley picks out for emphasis special features of the work of the Organisation which he regards as specially important or noteworthy. He then indicates certain difficulties inherent in the early years of a young organisation and some achievements which warrant confidence in its future. Next he deals with some current criticism of its activities, and, suggesting that the unifying idea behind all the activities of Unesco is the advance of world civilization, he records finally some of the conclusions which he has reached as a result of the three years he has spent with the Organisation.

Before examining Dr. Huxley's conclusions, it is as well to note that both the report and speakers in the House of Lords debate clearly distinguished between the administrative weaknesses and the character as well as the execution of the programme of the United Nations Educational, Cultural and Scientific Organisation. These two aspects have been much confused in current criticism, and it should be noted that, as Lord Addison pointed out, in replying to the debate on behalf of the Government, great improvements have already been made on the administrative side in the financial control. The statement on this point made by the auditors, which Lord Addison quoted, is explicit and re-assuring. While the laxity in the expenditure of public money in 1946 cannot be condoned, there can be little room for doubt that the Organisation is outgrowing some of those administrative difficulties inherent in any body which is staffed by several nationalities.

Policy, however, or the general programme of the Organisation, is another matter from accounts or day-to-day administration, and it is here that much criticism appears to be unsound and sometimes badly misplaced. Dr. Huxley's report should help to put matters into a true perspective and to stimulate constructive criticism at the points where it is most needed and where it can be most effective. The general approval of the central idea of promoting a better understanding between the peoples of the whole world which lies behind all the activities of Unesco has not prevented a considerable amount of criticism of the general policy and tendencies of the Organisation; and the one main criticism which Dr. Huxley is disposed to admit is that greater attention should be given to the formulation of a central idea or aim which the ordinary citizen can understand and appreciate. It is for this reason that, as already indicated, he suggests that the underlying idea is the advance of world civilization. The advance of civilization on a world basis is regarded by him as both practical and concrete, the summation of a series of definite and limited tasks, without introducing a note of ideological theory. It commends itself immediately to the educated portion of the world's population and can be readily made intelligible and desirable to the rest. It can readily be fitted into the broader concept of evolutionary progress but is quite independent of it.

Dr. Huxley does not attempt to formulate a detailed definition, but directs attention to the large area of common agreement as to the meaning of his terms. The advancement of civilization clearly implies the better cultivation of the arts of peace; the advance of knowledge and the exploration of new outlets for creative activity and expression; the emergence of new enjoyments and new possibilities of individual and social development; and, in terms of Unesco's competence, although it demands an increasingly complex material basis and social organisation as its foundation, it is primarily concerned with science and culture and with education as the method of transmitting them. In arguing thus, Dr. Huxley does not over-stress the place of science and scientific technique, the dominance of which was deplored in the House of Lords debate by the Bishop of Chichester, who stoutly challenged the view that science by itself could do much to improve the world, and pleaded eloquently that in the future development of the Organisation special attention should be paid to culture in all the richness of the meaning of that word. This speech, although a protest against excessive preoccupation with the material aspects of civilization, clearly recognized that science itself is one of the cultural elements in human life. Dr. Huxley similarly suggests that the advance of civilization consists essentially in the development of the higher activities of the human mind and spirit which can be shared without being destroyed or divided quantitatively. The idea of world civilization, moreover, transcends both nationalism and the collaboration of separate sovereign nations, and one suggestion put forward by Dr. Huxley for consideration is that Unesco should delegate an important part of its work to private individuals chosen, not as official delegates of Governments, but as leaders of civilization—outstanding thinkers, artists, writers and men of science, owning their allegiance not to nations but to humanity—representatives of departments of the human mind. Such private individuals would be in a position, Dr. Huxley believes, to give a lead to a unitary world civilization on many subjects where official delegates would be restrained; and in particular that only to such individuals could be entrusted the task of defining the phrase 'world civilization' and of describing what Unesco should do for its advancement. He visualizes the growth in this way of another international non-governmental organisation which would possibly act as a general spearhead for the Organisation.

This outlook is probably too optimistic, as is also the theme that the advance of world civilization necessarily excludes ideological differences. It is the totalitarian systems that represent the greatest obstacle, far greater than ascetic philosophy; for they deny the human freedoms on which creative activity depends, and they would render sterile and ineffective the participation of individuals, however eminent, in such an organisation as is suggested. They deny the loyalty to a world civilization which is presupposed, and require subscription to new dogmas which may not be scrutinized by the free spirit of scientific inquiry.

That obstacle has to be recognized; but nevertheless it is right to advocate increasing delegation of discussion in particular fields to the unofficial and individual level. Much of Unesco's most valuable work has, in fact, been done in this way. Already, the International Scientific Unions are functioning more effectively because of the help given to them by the Organisation, which has contributed during 1947 and 1948 about half a million dollars in grants-in-aid to the Unions, and has been instrumental in the formation of a new International Union for the Protection of Nature.

The wisdom of using existing organisations in this way cannot be challenged, and with its fellowship programme, facilitating the interchange of men of science and other scholars and its work in the reconstruction and rehabilitation of learned institutions, the Organisation has solid achievements to its credit.

Two of these spheres of work should find a permanent place in the programme of the Organisation, even when the reconstruction and rehabilitation work is completed and the "Book of Needs" no longer issued. Moreover, it will be noted that totalitarian regimes such as Soviet Russia have taken no more part in such activities than they have in Unesco itself, a fact that in itself demonstrates how far we have yet to go before we can speak with any sense of universality of a 'world civilization'. That, however, constitutes the real challenge to the creative and constructive thinking that should precede both criticism of Unesco's present programme and the formulation of alternative plans for achieving human understanding.

The very existence of the United Nations Educational, Scientific and Cultural Organisation is a challenge to men of science, philosophers, artists, writers, teachers and thinkers everywhere. To achieve a deeper sense of intellectual and moral solidarity between the nations of the world is an exacting task, but may be a condition of the survival of mankind. The methods by which it is to be achieved may still require discovery, and the task is far too large and important to be left to the permanent officials and delegations of the Organisation alone. It is already clear that American men of science are making a real attempt at such constructive thinking, as are shown by Dr. Bok's article "Unesco and the Physical Sciences" in a recent issue of the *Bulletin of the Atomic Scientists* and the replies received to the inquiry on "Science and the Maintenance of Peace" initiated last June by the Committee on Science and its Social Relations of the International Council of Scientific Unions. British scientific workers and other men of learning will have to co-operate more fully with their American and other colleagues to enable the purposes of Unesco to be achieved and its projects stripped of the vagueness of which Lord Simon in particular commented in the House of Lords.

Certain other points in Dr. Huxley's report should help in such thinking. He stresses, for example, the need for giving closer attention to the raising of education, science and culture to the international plane ; and, indeed, beyond that to a plane where they can be treated as aspects of the welfare of humanity as a whole. For support he looks to a *rapprochement* between scientific method and empirical practice in the higher reaches of human psychology. The social sciences have also important contributions to make to the solution of such problems as the mobilization of leaders of thought and creative expression throughout the world to carry forward the idea of a world civilization ; they assist both governments and peoples to comprehend the importance of the arts and of the æsthetic and emotional, as well as the scientific and intellectual, foundations of a world civilization.

The comparative neglect of art by Unesco is recognized by Dr. Huxley ; but here, as in the field of culture generally, great care and constant scrutiny by creative, practical minds will be needed to see that projects do not become vaguely idealistic. Last but not least, what he has to say about Unesco's contribution to world peace deserves attention. The programme of the Organisation is, it is true, in large part designed to lay the foundations for a more united and peaceful world ; but this should not be taken to mean that all its activities must be directly and immediately relevant to the preservation of peace. Some of its effort must be directed towards setting up the mechanism required for the existence of a truly peaceful world ; but that mechanism in itself is no guarantee of peace and could even in certain circumstances be turned against peace.

To provide a clearing house of information, a common pool of information on which all nations can draw in solving their own immediate educational, scientific and cultural problems, to assist the more efficient organisation of research in the natural and the human and social sciences so as to facilitate the solution of the problems of humans as a whole—these are recognized as essential elements in the function of adapting knowledge for the common good. No less important is that of distributing grants in aid of approved projects, whether their execution is entrusted to Unesco itself or to other bodies, and the need for careful scrutiny and constructive criticism of such projects ; nevertheless, Dr. Huxley is right in pointing out that concentration on three or four projects would not suffice to achieve the real purpose of Unesco, and to secure that men in all nations recognized and accepted a new and compelling loyalty.

We can, in fact, only be content that Unesco should concentrate for the present on a short-term programme provided that the creative thinking that must form the basis for long-term schemes is proceeding. We are only on the threshold of learning how to treat tensions affecting international understanding, and there is little to guide us along sound lines of approach. Professional associations, not only of scientific workers but also of teachers, writers, artists and many others, can make a vital contribution to the work of the Organisation in such matters. Dr. Huxley's report contains much material to stimulate the thought which will be required. British men of learning will surely not fail to follow the outstanding lead already given in the United States, and take a worthy part in the elaboration of an adequate programme and also in ascertaining the philosophical foundations for it.

MODERN RESEARCH IN RETINAL PHYSIOLOGY

Sensory Mechanisms of the Retina

With an Appendix on Electroretinography. By Dr. Ragnar Granit. Pp. xxiii+412. (London, New York and Toronto : Oxford University Press, 1947.) 35*s*. net.

THIS book is not a general treatise on vision, but deals in detail with some additions to visual physiology in the last fifteen years that have been derived from the study of action potentials of the retina and the optic nerve, and particularly with work in this field with which the author has been closely associated and in which his laboratory has been notably active. It has been possible in many types of visual sense organ to record nerve impulse discharges set up by the stimulus of light ; in work on a simple eye (*Limulus*), Hartline showed that visual sense cells, like other sensory nerve endings that have been investigated, set up impulses of frequency related to the strength of the stimulus, and Hartline later confirmed this for single optic-nerve fibres from the frog's retina. But here the response was complicated by fibres responding when the light was extinguished—the well-known off-discharge found by Adrian and R. Matthews in the eel's optic nerve. Granit's work has extended this investigation to mammalian eyes ; and the response in single optic-nerve fibres in many eyes has been studied and related to the wave-length of the light evoking it.

The author's dominator-modulator theory of colour vision is considered in detail, though the elaborate transformations to which the experimental results are subjected in order to yield the modulator curves are scarcely sufficiently stressed, nor are the many assumptions implicit in these transformations considered. Hartline has given clear evidence in the frog's retina of the large number of retinal elements converging on to a single optic-nerve ganglion cell. Granit's work has shown that both rods and cones converge on a common final path. It seems to the reviewer that Granit's observations have not demonstrated the presence of distinct pathways for the clearly distinguished modalities required to fit any of the existing colour-vision theories. As the existence for specific colour pathways has not been clearly demonstrated, if animals possess wave-length discrimination, it must be considered whether it is possible that the modalities can be transmitted by a single fibre by the pattern of impulses occurring in the final common path. There is some evidence in Granit's work, briefly mentioned, that the relative proportions of the on- and off-discharge of a single fibre are greatly influenced by the wave-length of incident light; this observation would appear to merit much more consideration than it has yet been given, and more detailed experimental exploration. It certainly suggests an escape from the present impasse produced by many observations that all the receptors present appear to converge on similar final common paths in the optic nerve; and it is difficult, therefore, to see how the higher centres can be informed of the particular receptors stimulated except by the patterns of nerve impulses occurring.

The book contains a wealth of interesting matter from the author's own experimental work taken from his many recent papers; but as a review of recent advances in retinal physiology it is a pity that more rigid selection was not used to reduce the excess of detail so that general principles would be more clearly defined. This makes the book more valuable to the specialist than to the student; unfortunately, much of the detail given is in deduction from experiment without the experimental observations from which alternative treatments of the data might be tested.

The wealth of detail in the present volume shows clearly that visual physiology is in a state of rapid advance and almost embarrassed by the wealth of observation that has yet to be fitted into the theory; for the theory has not yet advanced sufficiently to accommodate all the newer observations, which sometimes, therefore, appear to be conflicting.

The volume is well produced with nearly two hundred illustrations and a large bibliography.

B. H. C. MATTHEWS

PHYSICAL CHEMISTRY OF HIGH-POLYMERIC SYSTEMS

The Chemistry of High-Polymers

By Prof. C. E. H. Bawn. Pp. x+249. (London: Butterworth's Scientific Publications, Ltd., 1948.) 17*s.* 6*d.* net.

NOTABLE advances in our knowledge of the physical chemistry of high-polymeric systems have been made by British chemists. This is particularly true of those parts of this subject concerned with the mechanism and kinetics of addition polymerization of vinyl compounds, the thermodynamics of solutions of rubber, the application of physical methods to the elucidation of structure, and the behaviour of high polymers under applied stresses. It is therefore the more surprising that the book under review is the first on this subject to be published in Great Britain. If such a volume has been long overdue, Prof. C. E. H. Bawn's book has been well worth waiting for and, in the reviewer's opinion, deserves, and will probably secure, a much wider range of readers than that for which it was written.

The complete study of a single high-polymeric system is especially instructive because it illustrates such a variety of chemical principles and problems. First comes the preparation, in the desired degree of purity, of the basic material to be polymerized. This, largely organic, aspect is omitted by Prof. Bawn, and it might therefore be argued that his title should read "The *Physical* Chemistry of High-Polymers". Next, the chemical route must be discovered by which the monomer is transformed to the polymer. Accordingly, the early chapters are accounts of the kinetics of the rate of formation, and the molecular size distributions, of the product. Two major routes are distinguished: polycondensation and addition polymerization. The former is much the simpler kinetically and involves the consideration of only one velocity constant. Addition polymerization processes have all the complexity of chain reactions and involve the following: initiation processes, which may be stimulated by catalysts or radiation or both, and suppressed by inhibitors; propagation reactions and their reverse; chain transfer; and termination by a variety of methods. Such complexity makes clarity of presentation at once essential and difficult to attain without loss of continuity, and the author is to be congratulated on the large measure in which he has succeeded. Minor corrections and omissions are bound to arise. For example, on p. 55 a mechanism for destruction of diradicals by *p*-benzoquinone is presented which is contrary to Melville's findings, and the expression at the bottom of p. 15 for photochemical initiation must surely be f(IM).

Polymer molecules are the very antithesis of the idealized collision-theory concept of an incompressible sphere. Their size and shape can be determined by very varied observations on solutions of polymers. These methods are critically discussed, and the author is careful to emphasize that owing to the flexibility of the chains the results obtained only refer to the condition of the polymer in the particular solvent concerned. The gross disparity between the size of an extended polymer-chain and a solvent molecule implies that the entropy of dilution is far from ideal. If the interactions between polymer pairs, solvent pairs and polymer-solvent pairs are also widely different, appreciable heats of solution may be expected. Both these factors must be disentangled and their origins understood if the colligative and other properties of polymer solutions are to be significant. Chapters 4–5 are models of clear elementary expositions of these topics.

The author next considers what can be discovered concerning the finer structure, that is to say, the molecular architecture, of polymers. The mechanism of formation is often suggestive, and chemical analysis may provide an answer of partial validity; but the least ambiguous methods are the analyses of the absorption spectra and X-ray diffraction patterns. The latter tool is particularly valuable also for the clues which it can provide as to the degree of crystallinity of a solid polymer.

Many lecture audiences will have seen 'bouncing putty', which typifies the unusual physical properties that a polymer may display. Appreciable progress towards the understanding of the causes of the various types of response to applied mechanical and electrical constraints has been made in the last ten years, and the author has given a lucid account of these researches.

In such a vast field, any author of an elementary text must be selective, and any reviewer must resist the temptation to complain if his hobby-horses are not ridden, provided the book fulfils the purpose for which it was written. Prof. Bawn has achieved his object brilliantly, and there can be little doubt that his book will rapidly and deservedly become a standard university text.

The publishers of the book have departed from the usual English scientific book practice in certain respects. *Times* New Roman type has been employed, and this contributes greatly to the ease of reading. The same cannot be said of the other features. There is no author index, and the subject index is both incomplete and badly cross-referenced. Where subdivisions of sentences or paragraphs occur, brackets are rarely placed round the number or letter. This makes for difficult reading even when the letters are italicized. On p. 46, brackets are employed, and the pleasing contrast with the earlier part of the same paragraph where they are omitted is most noticeable.

F. S. DAINTON

MOHENJO-DARO AND HARAPPA

Early Indus Civilizations

By Dr. Ernest Mackay. Second edition, revised and enlarged by Dorothy Mackay. Pp. xiv + 169 + 30 plates. (London: Luzac and Co., Ltd., 1948.) Stiff paper, 15*s.*; cloth, 17*s.* 6*d.*

STUDENTS of Indian archæology will welcome this second edition of Dr. E. Mackay's useful text-book on the Indus civilizations. The magnificent volume of Sir John Marshall on "Mohenjo-daro and the Indus Civilization" is far too expensive for the average archæologist, and the other publications of the Archæological Survey of India are also expensive and not easily accessible. In this new edition the illustrations have been enlarged and increased in number; but it is a pity that the amulets referred to on pages 59–60 are not included in the additional illustrations

Interpolations have also been made in the text to bring it up to date in accordance with the results of field-work carried out since the first edition was published, and an addendum at the end gives a general view of the conclusions to be drawn from this later work. Thus the linking up of Harappa material with Sumerian and Babylonian chronology involves a consequential change in Harappa dating which would nearly, if not quite, bridge the gap between the Indus civilization and the invasion of the Aryan-speakers. This implies a very long period at Harappa with a remarkably slow rate of change. There is nothing inherently improbable in this, and a parallel can be found in the continuing culture of Atchama-Alalakh which was reported by Sir Leonard Woolley in 1947. Other examples can be provided from Arabia, and such a slow rate of change is probably typical of India. It is not impossible that the cities and wealth of the Dasyus, Nagas, etc., mentioned in the Rigveda and the early epics, have reference to the Indus civilization, and that the tradition which describes the Dasyus as black and noseless may have been taken over from a race of previous invaders and interpreted in the course of time as referring to the immediate precursors of the Aryan-speakers.

The graphs on the seals are also discussed, but it is unlikely that these inscriptions will be deciphered until some bilingual record with a second character has been discovered.

The index has been extended, and there have been added an air photograph of the Mohenjo-daro site and plans of the city. The number of plates has been doubled, but the absence of scale is a serious drawback; for example, there is nothing on the plate to tell the student that the steatite bust depicted on Plate 16 is not life-size, instead of being, as it is, on a miniature scale; one may be permitted to hope that the next edition will give not only scales to the illustrations, but also some reference to the relative pages of the text.

J. H. HUTTON

BEQUEST TO BIRD-LOVERS

Birds in Britain

By Frances Pitt. Pp. viii+576+17 plates. (London: Macmillan and Co., Ltd., 1948.) 25*s.* net.

DURING the Second World War the amount of bird-watching and the number of bird-lovers in Britain increased considerably. This has led to a steady stream of books on birds and their behaviour, to cater both for the experienced bird-watcher and for the enthusiastic beginner. But no apologia need be made for the appearance of yet another book on birds, since "Birds in Britain" is the fourth of the now well-established "in Britain" series which have been enthusiastically received by many readers. Previous issues in the series have dealt with flowers, trees and dogs, and now comes Miss Frances Pitt with her long experience and discerning eye. In her book are found not only scientific accounts of wild and domestic birds in Britain but also personal anecdotes which enliven the text and captivate the reader. Her experiences have been gathered in many parts of the British Isles and have given her an 'understanding' of birds which, by description, she successfully transmits to her readers. These descriptions are supplemented in many instances by well-chosen and apt literary references both from the classics and lesser-known works.

Nor is the text the only delightful feature of this book. The frontispiece consists of a painting by Winifred Austen on which it would be hard to improve either in the original or as a reproduction. Roland Green has painted a series of sixteen plates which, because of their natural effects, are a joint tribute to artist and publishers. Miss Pitt herself has contributed a number of clear, explanatory line drawings, and the book is also provided with a large number of black-and-white photographs drawn from the rich store of our leading bird photographers. The reproduction of some of these is probably the only blemish in a book which will be of value to the specialist, and generate enthusiasm with the not so learned. For the specialist better accounts of certain topics like "Birdsong", "Migration" and "Territorial Behaviour" may be found elsewhere; but it is probable that of all works on birds this book comes nearest to providing something of interest both for the specialist and the novitiate. There is evidence that its predecessors have helped to kindle the enthusiasm of many beginners in the study of trees and flowers, and it will not be surprising to learn later that "Birds in Britain" has increased the number and knowledge of bird-lovers in Britain.

T. H. HAWKINS

Symposium on Methods of Penicillin Assay

Their Purpose, Scope and Validity. (The Society of Public Analysts and Other Analytical Chemists: Physical Methods Group and Biological Methods Group.) Pp. iv + 34. (Cambridge: W. Heffer and Sons, Ltd., 1948.) 3*s.* 6*d.* net.

MUCH of the value of scientific symposia and conferences is apt to be lost in these days of publication difficulties. For example, the papers read at the International Congress of Pure and Applied Chemistry some eighteen months ago remain unpublished, except as abstracts on bits of common paper. It is therefore especially commendable that the Society of Public Analysts and Other Analytical Chemists (like the Biochemical Society also) has achieved relatively prompt publication of symposium papers. The symposium on "Methods of Penicillin Assay" was held on January 29, 1948, and was reported in *Nature* of February 21, p. 285. The papers and discussion were published in the April and May issues of *The Analyst*, and have since been reprinted as a handy stiff-covered booklet, uniform with reports of previous symposia on polarography, chromatography and spectroscopic analysis. The report can probably claim to cover every known method (about forty in all) for assaying total penicillin or individual penicillins, by chemical, physical or biological means. Its importance lies not only in this completeness, but also in the fact that some of these methods have not been published previously, except in war-time reports of limited availability. It is unfortunate that some important methods are mentioned only in the introductory surveys, and therefore briefly, while there are full papers on others of less importance. However, this kind of uneven weighting is inevitable at any symposium.

Working Plans for Estate Woodlands

By N. D. G. James. Pp. ix+93. (Oxford: Basil Blackwell, 1948.) 6*s.* 6*d.* net.

IN the past it was not so much the owners of estates as their factors and agents who were against the 'working plans' for woodlands. It is all to the good that Mr. N. D. G. James emphasizes in a book of considerable merit the importance of the necessity for making plans for small woodlands. He explains clearly enough the form the plan should take, and how information and statistics should be collected. This is all good, concise and clear. He correctly insists on the formation of compartments and other allotments or divisions of the areas, but a serious omission is that nothing is said about yield calculation; this title is even omitted from the headings given of the plan. The intention is expressed of not wishing to frighten owners with complexities and unnecessary technicalities, but one cannot call the calculation of the yield either the one or the other, for the necessity is obvious.

I am unable to follow the author in his divisions of the 'working plan' into three under the titles of a "Full Plan", an "Intermediate Plan" and a "Short Plan". The 'working plan' remains as such whether made for (1) a large area of forest with at present only a small demand for its produce and thus requiring only a simple plan; (2) a large area of forest under intensive management requiring detailed plans; or (3) an area of simple coppice requiring only a simple prescription. The main headings of the 'working plan' are the same for all, and any modifications required can be made in the prescriptions, such as planting, natural regeneration, felling proposals and so forth. It is suggested that pages 6–15 dealing with the headings of the three types of plan are likely to prove intimidating to the owner. Altogether this book is quite a good piece of work in many of its parts; the omission of any methods of calculating the yield is a pity. In his fear of becoming complicated and complex in items of management, the author seems to have unnecessarily complicated simplicity.

E. P. STEBBING

Poudres et explosifs

Par Henri Muraour. (Que sais-je ?, les points des connaissances actuelles, No. 259.) Pp. 136. (Paris: Presses universitaires de France, 1947.) n.p.

THE author of this volume has had unusual experience in writing about his subject; the present work is mainly addressed to those with some scientific background who wish to have a brief but broad account of the nature, classification and testing of organic explosives, and of their future military uses as propellants, in minefields, and for demolition purposes. The format somewhat resembles that of the 'Penguin' series.

For those with some acquaintance with the subject, interest will centre on the chapter on the decomposition process, which includes records of work by the author and his colleagues. The detonation of initiators *in vacuo* is explained by a chain mechanism in which activated decomposition-products bring about further reaction by 'resonance' with unchanged molecules. The *brisant* nature of initiators may be annulled if they are ignited in a high-pressure gas; this phenomenon is left unexplained, pending further investigation.

For high-explosives, the hydrodynamic theory, as elaborated by Schmidt, Jouguet and others, is adopted. Here the experiments of Muraour have included studies of the luminosities of shock waves in monatomic gases; the higher figures found in argon as compared with helium are explained as being due to the higher atomic weight. Vassy found that four millilitres of a mixture of tetranitromethane and toluene, when detonated in argon, gave an intensity of four hundred million candle-power in a flash, lasting four millionths of a second. Comparison of these shock-wave intensities with those produced by meteors promises to give interesting results.

W. E. BATTY

Directory of Museums and Art Galleries in the British Isles

Compiled by Major S. F. Markham. Pp. viii+392. (London: Museums Association, 1948.) n.p.

ALTHOUGH much of the information contained in this directory is also available in the Libraries, Museums and Art Galleries Yearbook, 1948, those who are not chiefly requiring information about libraries or about overseas institutions will probably find the directory the more convenient to use. The information given is slightly fuller, and some details are supplied of museums closed through lack of local interest or of financial support, those destroyed or damaged by enemy action and those occupied by Government departments. Museums closed at December 1947 are listed in an appendix, with remarks on the situation and prospects of re-opening. Although the volume includes no index, the alphabetical arrangement by towns and villages is adequate for most purposes, and the book is well printed and produced.

R. B.

NINTH INTERNATIONAL CONFERENCE OF WEIGHTS AND MEASURES

THE ninth International Conference of Weights and Measures was held in Paris in October last. Under the terms of the international treaty known as the Convention du Mètre, these Conferences should be held every six years. But on this occasion the Conference which should have taken place in the autumn of 1939 had had to be deferred, owing to the Second World War, until 1948, with the result that the normal interval was increased to fifteen years.

In the meantime the International Bureau of Weights and Measures at Sèvres had pursued its activities, though not without difficulties both financial and technical, due to the abnormal conditions of the times. In particular, the International Committee which governs the Bureau under the general authority of the Conference was also unable to meet between 1937 and 1945. It will be appreciated that, in these circumstances, many changes had occurred in the interval, and the 1948 Conference had before it an unusually heavy agenda.

The opening session took place in the Salon d'Horloge at the Ministry of Foreign Affairs in Paris, under the presidency of the French Foreign Minister, M. Robert Schuman. Subsequent meetings were held at the International Bureau under the presidency of M. Henri Villat, the president, or his deputy, M. Louis de Broglie, the permanent secretary of the Paris Academy of Sciences. The members were also entertained by M. Vincent Auriol, the French President, at an informal reception at the Elysée.

The Conference was attended by fifty-five representatives of twenty-eight States adhering to the Convention. Only five States were unable to send delegates: two of them, Germany and Japan, because, at the time, they were without autonomous Governments. Great Britain was represented by Sir Charles Darwin, director of the National Physical Laboratory, Mr. H. Barrell, the official delegate, and Mr. J. E. Sears, president of the International Committee, which was in session concurrently with the Conference and functioned in an advisory capacity. It will doubtless be remembered that the International Committee itself enjoys the assistance of three technical consultative committees, for electricity, for photometry and for thermometry and calorimetry.

The first session was purely formal, being confined to a speech of welcome by M. Schuman, and replies by Mr. Sears and M. Villat. The first business at the second session was the establishment of the credentials of the official Government delegates who held the right of vote for their respective States. At this stage there was an intervention by the Russian delegation, who objected to the presence of Spanish representatives at the Conference; they directed attention to the refusal of the United Nations to admit Spain to membership. It was pointed out that the Convention du Mètre had no connexion with U.N.O., that its functions were entirely non-political, and that each contracting State, having paid its subscription, was equally entitled to participate in the proceedings of the Conference. Although the Russian delegation formally reserved the right to revert to this question, it was not, in fact, raised again.

The Conference then proceeded to the consideration of the various items on its agenda. Mr. Sears reported on the activities of the Bureau since the previous Conference, in 1933, and asked for formal sanction to the results of comparisons made, during the past fifteen years, of various national copies of the metre and kilogram. These results were highly satisfactory. With the exception of two kilograms, the masses of which were known to have diminished owing to wear, the new values, both for the metres and the kilograms, agreed, within quantities small enough to be accounted for by the combined errors of the two determinations, with those obtained when the standards were first authorized in 1889. Incidentally, it was reported that the historical Kilogramme des Archives, also included as a matter of interest in the recent re-comparisons, showed a diminution of mass of 0·4 mgm. This caused no surprise, as the material of construction of this old weight is known to be inferior to that of the international standards. It may be remarked that the British Standard Pound, the material of which may be supposed to be similar to that of the Kilogramme des Archives, has exhibited a similar loss relative to the current metric standards.

Consideration was next given to the possibility of the eventual replacement of the material prototype standard of the metre, in platinum-iridium, by a definition of the unit of length based on the wave-length of light. This is an old proposal which has received a considerable impetus in recent years as a result of the separation of sensible quantities of isotopic materials—in particular of krypton-84 in Germany and of mercury-198 in the United States. These isotopic elements provide sources of even more homogeneous radiations than the red line of cadmium which has hitherto been accepted as the standard of reference for spectroscopic measurements, and open up the possibility of a new definition of the unit of length, free from the objections hitherto urged against the use of a wave-length of light for this purpose, which would afford the prospect of a clear advance in precision. The Conference voted a resolution recognizing these facts and inviting the principal national laboratories and the Bureau International to pursue the study of these new sources with the eventual object of establishing such a definition.

The next subject to be considered was the value of the acceleration due to gravity. Determinations at the National Physical Laboratory, Teddington, and at the National Bureau of Standards, Washington, have indicated that the accepted reference value for standard gravity, derived from the earlier Potsdam determinations, is appreciably in error. All these values result from pendulum observations. Experiments have already been initiated with the approval of the Committee at the Bureau International with a view to a new determination by direct observation of the movement of a body (a graduated line standard) falling *in vacuo*, using modern techniques for the precise measurement of times and displacements. Recommendations in nearly similar terms were submitted to the Conference by the Russian and Spanish delegations urging the desirability of further gravity determinations. After discussion, the Conference voted a resolution recognizing the interest of the work already in hand at the Bureau, and inviting other laboratories which may be in a position to do so to undertake comparable measurements.

On the subjects of electric and photometric units, the Conference had little to do except to take note of, and confirm, the decision already taken by the International Committee, in pursuance of the instructions of the previous Conference, that the new units should come into force as from January 1, 1948. It may be worth while to recall that the relationship of the old to the new (absolute) electric units is 1 mean international ohm, $\Omega_M = 1{\cdot}00049$ absolute ohm; 1 mean international volt $V_M = 1{\cdot}00034$ absolute volt; and that the new unit of candle-power, which in future is to be designated 'candela', is defined as "such that the brightness of an integral (black body) radiator, at the temperature of solidification of platinum, equals 60 candela per square centimetre".

With regard to thermometry, the Conference accepted a revised text of the International Temperature Scale, recommended by the International Committee on the advice of its consultative committee. This is a very detailed statement. It may be useful to record that the primary fixed points of the scale are:

	Temperature 0° C.
Boiling point of oxygen	−182·970
Melting point of ice (fundamental point)	0
Boiling point of water (fundamental point)	100
Boiling point of sulphur	444·600
Solidification point of silver	960·8
Solidification point of gold	1063·0

Temperatures in the revised scale are to be quoted as °C. (Int. 1948). It should also be mentioned that, after discussion, it was unanimously agreed to describe temperatures in this scale as degrees "Celsius" instead of Centigrade or Centesimal. Objections were raised to both the latter on different grounds.

Turning to a more fundamental question, it was agreed that the thermodynamic scale should, in principle, be based on a single fixed point, namely, the triple point of pure water, which should have the value + 0·0100 degree, together with the absolute zero, the value of which should be fixed at a later date, when more precise measurements are available.

It was also agreed that the unit of heat should be the 'Joule', and it was remitted to the International Committee to establish a table relating the value of various 'calories' to the Joule, in accordance with the best available experimental data.

The Conference also referred to the Committee the task of instituting an inquiry among all the contracting States as to the opinions held with regard to the possible formulation of a common practical system of units of measurement suitable for adoption by all countries using the metric system, and of making recommendations.

Following an initiative of the International Union of Physics, the Conference adopted a table of nomenclature and symbols relating to a selected group of quantities which were held to come within its domain. It also approved a proposed recommendation that, so far as Europe is concerned, words ending in ". . . illion" should be accepted as referring to successive powers of 10^6.

Approval was given to a proposed agreement for mutual co-operation between the International Committee and the United Nations Educational, Scientific and Cultural Organisation on questions of common interest.

The Conference next addressed itself to the regulation of the scale of subscriptions for the various countries adhering to the Convention. Proposals for further extensions of the activities of the Bureau were put forward by the Russian delegation and referred to the Committee for study. A suggestion was made by the Swiss delegate that the Governments of the contracting States might be invited to supplement their statutory contributions by voluntary donations to facilitate such additional undertakings.

Finally, the Conference proceeded to the re-election of the International Committee. Many members of the Committee elected in 1933 have since died. In addition to seven former members who retain their seats, the following were elected, or re-elected after retirement by rule: L. de Broglie (French), G. Cassinis (Italian), E. C. Crittenden (American), M. Dehalu (Belgian), W. J. de Haas (Dutch), T. Isnardi (Argentine), H. Nagaoka (Japanese), Z. Rauszer (Polish), M. Siegbahn (Swedish).

The Conference passed in an atmosphere of friendly co-operation, and it will be seen that it accomplished successfully a large programme of work covering a very wide field.

EVOLUTION OF COLOUR VISION

A DISCUSSION of the evolution of colour vision took place at the general meeting of the Linnæan Society on February 24. Dr. R. J. Pumphrey, while disclaiming expert knowledge, said that it seemed fitting that a zoologist should have been invited to open the discussion rather than a specialist in human colour vision, however knowledgeable, since a zoological training enforces a historical outlook, which is essential for the ultimate understanding of the evolution of function. The evidence available from animals other than mammals, though extremely relevant, is still scanty; inferences from structure and physiology cannot be relied on. Colour vision can only be ascribed to an animal when the intact animal, either in the field or in a controlled experimental situation, has been shown to exercise a choice depending on colour discrimination. Such a test is always a matter of extreme technical difficulty, and is not applicable to any animal without restriction but only to those whose habits and motivation make them suitable subjects. In spite of these limitations, colour vision has been demonstrated beyond reasonable doubt in a number of insects, notably aculeate Hymenoptera, Diptera and Lepidoptera, and a number of vertebrates, notably teleost fish, reptiles, birds and primates.

This demonstration leads immediately to two obvious questions. To what extent is the fundamental mechanism of colour vision similar in these animals? And to what extent is it utilized in a similar way? To the first question, the best available answer comes from measurements of the least perceptible difference in wave-length ($\Delta\lambda$) of pure spectral colours as a function of wave-length. This function is of identical form for man (Wright), pigeon (Hamilton and Coleman) and minnow (Wolff). The maximum and minimum values of $\Delta\lambda$ occur at the same values of wave-length λ. For the bee the curve has the same general character but is displaced, one minimum value of $\Delta\lambda$ being in the ultra-violet near 3800 A. (Kühn). It is reasonable to conclude that in all these cases colour vision depends on the existence of three or more types of photoreceptor with different absorption spectra. None of these curves has the least resemblance to the discrimination curve of a human dichromat, although it has been suggested that dichromatism is an essential stage in the evolution of full colour vision.

It does not follow, however, that colour vision has the same character in all these animals. Kühn's work appears to show that the effect known as simultaneous colour contrast, which is of trivial importance in human vision, is dominant for the bee. If this be the case, no object of small angular subtense in the bee's visual field will be intrinsically coloured; its apparent hue will depend primarily on the background against which it is seen.

The human eye unaided cannot distinguish spectral green from a suitable mixture of spectral blue and yellow, but a match so made will no longer be a match when seen through a coloured filter. A proportion of the cones of a bird's retina contains red and yellow oil droplets each of which is a colour filter for its own cone. Hence it is obviously physically possible for a bird to distinguish impure colours which are indistinguishable to man without extraneous aids. These examples indicate that in spite of a fundamentally similar mechanism of colour vision in different animals, the quality and extent of the information about the environment which their eyes collect need not be the same or even similar.

The fact that colour vision appears to be demonstrable in just those animals whose habits lend it a particular importance suggests that the fundamental mechanism is an essential attribute of any highly organised eye, and one which may or may not be exercised in the direction of colour vision according to need. Hartline's and Granit's demonstration of receptors of different spectral sensitivities in the retinæ of a number of animals which are certainly colour-blind supports this conclusion.

Dr. E. N. Willmer said that, in spite of many attempts, colour vision had not been demonstrated in any mammal outside the primates. The primate stock was in all probability nocturnal in habits, with a retina dominated by rods, a rod being defined as a visual receptor cell containing rhodopsin and being maximally sensitive at 500 $\mu\mu$. A cone contains a pigment other than rhodopsin and is maximally sensitive at 570 $\mu\mu$. Histologically, although they are typically very different, they may in certain species and situations be difficult to distinguish. Moreover, rods themselves may differ widely in their power to accumulate rhodopsin, and Granit has demonstrated the existence of distinguishable groups of high- and low-threshold rods in cats and guinea pigs. It is probable that, in view of their evolutionary history, the mechanism of colour vision in mammals may be quite different from that of birds, which is probably wholly dependent on cones. Dr. Willmer said he would submit evidence that in primates colour vision depends on rods and cones; neither alone can produce the sensation of colour.

In the colour vision of primates, the most important part of the retina is the central part of the *macula lutea*, which is called the *fovea*, and subtends an angle of about 2°. Within the fovea is the central 'rod-free' area subtending less than 1°, with greatly diminished power of dark-adaptation and containing no low-threshold rods. The normal fovea in man is trichromatic and must contain at least three types of receptor elements with separate pathways to the colour-analysing centre of the brain. The rod-free area, however, behaves as a dichromatic system. Within it all spectral colours can be matched by mixtures of red and violet.

Subjects who confuse red and green (both protanopes and deuteranopes) are completely colour-blind in the rod-free area. Any spectral hue can here be matched to any other by altering its intensity only. They differ, however, in the spectral sensitivity of this area, protanopes being relatively insensitive to red and deuteranopes falling into two classes, normal (type I) and relatively insensitive to blue (type II), respectively. It is inferred that the sensitivity curves of the protanope and the deuteranope (type II) represent respectively the spectral sensitivity of the two elements normally present in the rod-free area. For the deuteranope (type II) the inference is strongly supported by the way in which the thresholds for red and violet light respectively are modified by previous exposure to high intensities of red or violet. The deuteranope of type I has normal sensitivity and adaptation, indicating that both 'red' and 'green' receptors are present in the central rod-free area; but he is colour-blind because their output is not recognized as distinct by the central analyser. The deuteranope (type II) is colour-blind in the central fovea because only the 'red' receptors are present. Further, the sensitivity curve of the 'red' receptors is not so unlike the absorption spectrum of iodopsin as to exclude the idea that the 'red' receptors are, in fact, cones in which iodopsin is the sensitive pigment. In spite of certain complications in the adaptation results, it is probable that the protanope is colour-blind in the rod-free area because only 'green' receptors are present.

Histologically, two trends are distinguishable in the evolution of the primate retina: the specialization of the rod + mop-bipolar system for dim-light vision and of the cone + midget bipolar in the centre of the retina for good acuity at higher illumination. These lead ultimately to the existence of three pathways in the eye as a whole and two in the central fovea. The pathways are formed by the mop-bipolars relaying from low-threshold rods (the 'blue' pathway), the flat bipolars relaying from high-threshold rods and cones (the 'green' pathway), and the midget bipolars relaying from cones only (the 'red' pathway).

Both histological evidence of the evolution of the retina in primates and the evidence from the examination of colour-defect in man, Dr. Willmer said, are consistent with the existence of three types of receptor only, namely, cones, high-threshold rods and low-threshold rods, the two first only being present in the 'rod-free' area.

Admiral T. P. H. Beamish stressed the continuing importance for the Services of research on colour vision, relating that his own yeoman of signals had been found to be colour-blind after thirteen years of service. Dr. L. C. Thomson pointed out that Dr. Willmer was relying heavily on the fact that protanopes are totally colour-blind in the rod-free area. In Dr. Thomson's experience, this was not altogether true and a time factor was involved. The subject is conscious of a colour sensation initially, which changes or vanishes on continued fixation.

Dr. H. J. A. Dartnall raised the question whether the absorption spectrum of iodopsin is sufficiently close to the sensitivity curve of the deuteranope, type II, to justify the assumption that human cones depend on iodopsin.

Prof. H. Hartridge said that he could confirm the old observation of Holmgren that a bright yellow point centrally fixated could be seen as red, white, green or yellow and a blue point as green, white, blue or violet. How was it possible to reconcile this observation with the existence of only two receptor types in the central fovea ?

Dr. M. H. L. Pirenne suggested that more use might be made of the opto-motor reaction in investigating the colour-vision of animals by a method similar to that used by Hecht in determining acuity.

Dr. Willmer, in reply to Dr. Thomson and Prof. Hartridge, said that it was not really relevant to argue about whether or not a colour sensation was aroused in the subject. The crucial question was whether the sensation, whatever its subjective nature, could be matched tri-, di- or mono-chromatically.

Dr. Pumphrey, in reply to Dr. Pirenne, said that the difficulties of the technique suggested, if not insuperable, were so formidable that suspicion might attach to the results. The method had, in fact, been tried by Birukow on the frog with results in conflict with those of other workers. R. J. P.

PHYSICAL AND PSYCHO-PHYSIOLOGICAL ASPECTS OF COLOUR

THE British Psychological Society and the Colour Group of the Physical Society held a joint meeting, their first, in the Hastings Hall, Tavistock House, London, on February 12, when a number of problems about colour were discussed. Mr. J. G. Holmes, chairman of the Colour Group, was in the chair. Three main topics were introduced by members of a panel consisting of Dr. L. C. Thomson (Vision Research Unit, Medical Research Council), Mr. R. C. Oldfield (Institute of Experimental Psychology, Oxford), Dr. R. W. Pickford (Department of Psychology, Glasgow), Dr. W. D. Wright (Department of Optics, Imperial College of Science and Technology, London) and Mr. W. A. Allen (Building Research Station, Department of Scientific and Industrial Research). General discussion of each subject followed the contributions of the panel.

Dr. Thomson spoke first, on "The Measurement and Meaning of the Luminosity Curve". He emphasized the difficulties of determining accurately the forms of this curve, and outlined the two principal methods, namely, (*a*) obtaining brightness matches for a series of monochromatic stimuli against a standard monochromatic stimulus ; (*b*) determining the absolute intensity-threshold for a series of wavelengths. By these methods the photopic and scotopic curves are obtained, and their form and relative position in the spectrum suggest a number of problems, of which Dr. Thomson detailed two. The first of these is that of the shift in the position of the luminosity curve as conditions are changed from scotopic to photopic, and in this connexion he made reference to Dartnall's suggestion that such a shift might be produced by selective absorption by increasing concentrations of the breakdown product of rhodopsin—indicator yellow—under increasing light intensities. Such a hypothesis would, he remarked, predict a limited shift of about the correct amount. The second problem about the luminosity curves raised by Dr. Thomson was that of the secondary maxima, or 'humps' found on the photopic curve. He pointed out that if these are connected with independent colour mechanisms, doubts must arise regarding that part of the Young–Helmholtz trichromatic theory which postulates that a sensation of white is the product of the activity of the three colour receptors alone, and of no other mechanism.

Mr. Oldfield referred briefly to some of the problems, physical and psychological, which arise concerning the position of the luminosity curve in the electromagnetic spectrum, and the biological utility of colour vision. He cited Wall's view that, since the vertebrate eye evolved in an aqueous environment, the absorption spectrum of water must be one of the factors determining the position and extent of the sensitivity curve of the eye. He mentioned other physical factors which impose similar limitations. On the question of the biological utility of colour vision, he referred to the difficulties of determining accurately its incidence among animal species, and remarked upon its somewhat odd occurrence. He suggested that its chief utility lies in the enormous variety of discriminable patterns of visual stimulation that it affords, compared to the resources offered by mere intensity discrimination. He asked whether the actual incidence of colour mechanisms might not be bound up with the food habits of the species concerned.

Dr. Pickford spoke next on "The Inadequacy of Existing Tests of Colour Vision". He remarked first that most tests are vitiated by the fact that they were devised with a theory of colour defect in mind. Indeed, he said, most would be quite useless if the phenomena of colour-blindness did not show marked discontinuities. The tests are satisfactory only in so far as they are responsive to distinctions between the colour-blind and the normal. They have little capacity to separate out the anomalies. He then briefly criticized a number of tests in common use. Holmgren's wool-test had been effectively disposed of by Edridge-Green, who showed that it failed in many cases to detect defects of occupational significance. Tests of the Stilling and Ishi-Hara type serve to reveal the chief discontinuous classes of colour defect, but scarcely do much to distinguish the protanope from the deuteranope. Edridge-Green's bead test depends on naming, and no test should depend on this alone ; further, its yellow-blue section is ineffective, and the test generally is too easily passed by defectives. Lantern tests such as those of Edridge-Green and Martin depend on naming, itself a complex function. They also suffer from extreme intricacy of procedure, if the instructions are fully complied with. Spectrometer tests, again, rely on the expression of discrimination in terms of names, and suffer from the disadvantage that they require an experienced worker to administer them. They are also unable to deal with the red-green anomalies. The anomaloscope, finally, is excellent for the detection and measurement of red-green anomalies, but is unsuitable for use on other types of defect.

Dr. Wright maintained that the available tests are not entirely unsatisfactory, provided they are used for purposes to which they are suited. In occupational testing it is important in the first place to pick out the grosser defects, and to select those subjects who require further testing of a more special character. The Ishi-Hara test and the anomaloscope together will achieve this. The more special tests should be devised so as to provide as close an imitation of the occupational working conditions as possible. Dr. Wright emphasized that, as an occupational problem, colour-blindness cannot be treated in terms of discontinuities. The appropriate borderline must be fixed in the light of each type of occupational requirement and circumstance. For the scientific investigation of colour defect, all that is required of the tests is that they should be able to pick out with reasonable reliability those individuals requiring more intense study by specialized laboratory methods. Existing tests such as the Ishi-Hara satisfy this requirement.

The discussion was then thrown open to the meeting, and a number of members took part. Several commented on the usefulness of the Ishi-Hara test in examining school-children, and the view was expressed that, if used in suitably defined and standardized conditions, especially as regards illumination, the test is an effective one. Some discussion took place on the relationship of intelligence to colour-vision test performance ; and the implications of supernormal colour discrimination were briefly examined, together with the part played by training and practice. A number of remarks were also made concerning the conditions and significance of binocular chromatic fusion.

Mr. Allen then spoke on "The Effect of Colourful Decoration and Lighting". He explained that these problems, which are of great importance to the architect, builder, and industrial manager, fall into two types. In the first place, colour effects can be used in factories and other places of work to promote, through broadly æsthetic channels, cheerful and pleasant states of mind conducive to efficient work and the avoidance of fatigue. In the second, there are more specific problems of promoting physiological well-being by such factors as the avoidance of glare, the production of a feeling of warmth, and so forth. The first, more æsthetic, group of effects allows considerable latitude in the choice of suitable colour schemes. But in the case of the second, choice is dictated by the particular problems to be solved. Mr. Allen gave examples in which such choice had been successfully made. In one case lighting conditions, and particularly the absence of glare, in recently built schools caused the teachers to insist that they felt markedly less strain in their work, while the children showed a smaller tendency to somnolence in the afternoons. Mr. Allen concluded by remarking that what had hitherto been done towards a solution of these problems had been upon a somewhat intuitive and *ad hoc* basis, and he appealed for an attempt to be made towards a scientific formulation of the necessary principles.

In the course of the subsequent discussion, attention was directed to the difficulties of investigation in this field. Mr. Oldfield emphasized the danger of drawing conclusions from short-term experiments. At the same time, he said, there is a natural hesitancy in embarking on long-term investigations involving great expenditure of time and effort where so little is known of the individual factors that may play a part. Mr. H. D. Murray expressed himself as disappointed with what the psychologists had at present to offer. He had hoped that some relatively simple indicator of the effect of these factors might be devised, though he acknowledged that those commonly used, such as output, minor accident-rates, etc., in investigation of the effects of more specific environmental conditions were inappropriate in this field. He said that any good suggestions, even if they afforded only partial solutions, would be very welcome to people in industry.

The chairman, in both his opening and closing remarks, stressed the importance of bringing psychologists, physicists and physiologists together for the common discussion of the problems of colour. He was sure, he said, that such contacts would be very fruitful in suggesting valuable and novel experiments.

R. C. OLDFIELD

THE ROYAL INSTITUTION AND SCIENTIFIC RESEARCH*

By PROF. E. K. RIDEAL, O.B.E., F.R.S.

THE free and unfettered pursuit of knowledge which Rumford and Davy laid down as the object of the Royal Institution has had surprising results. This is not the place to catalogue the vast list of scientific discoveries which have emanated from the laboratories and desks in this building from the time of Rumford to the time of Dale. We usually associate the names of workers in science with some particular achievement, because that particular piece of work has had a great influence either on modern philosophical thought, or on some modern branch of experimental or theoretical science, or again, in some field of technological endeavour ; but their other and less-known achievements in different fields are not to be ignored.

The spirit of freedom and of inquiry is like the wind which bloweth whithersoever it listeth, and it may be of interest to examine the contributions which workers in the Royal Institution have made to the subject of the physics and chemistry of surfaces and colloids, a field in which the laboratory is especially interested at the present time, and to compare the methods of experimental approach adopted by them with those now current.

We usually associate the name of Count Rumford himself with the concept of the mechanical equivalent of heat ; but we find that he was interested in surface tension, and held several classes on the subject. In a similar manner, Davy, associated by us with the discovery of the alkali metals by electrolysis, the definition of acidity and the physiological effects of nitrous oxide, was interested in the movement of crystals of potassium acetate on the surface of water, and remarked that their lively motion was retarded by a layer of oil.

Observing that small solid objects could float on a water surface and that it was generally attributed to air adhering to the surface, Rumford devised experiments to prove this was not the case. One simple experiment consisted in allowing a needle to fall on a water surface under ether, when the needle remained suspended at the ether–oil interface. He concluded that the particles of water adhere strongly to each other, forming, in consequence, a kind of pellicle at the upper surface. With this concept he interpreted the concavity of a water surface confined in a small vessel, the suspension of water in a capillary tube and the like. He inquired as to the form of the sessile drop and noted that the resulting film at the surface must be extremely thin.

Rumford observed that Laplace's attractive forces in that writer's theory of surface tension are to be identified with his adhesional forces. He commented on the great author of "Mécanique Céleste" as follows : "I must confess that I am not sufficiently well versed in higher geometry to understand fully the calculations of M. Laplace on this subject, and I shall take good care not to pass judgment on them . . . but I have such a high opinion of the talents of this man, that I am always inclined to receive his opinion in matters of science, as well as on every other subject, with the greatest deference".

---

* From a Friday Evening Discourse at the Royal Institution on March 4, in commemoration of its foundation on March 7, 1799.

It was doubtless Rumford's and Davy's work on surface tension that led Thomas Young to develop his well-known theory of cohesion and capillarity, which was singularly successful. Young was the first to deduce an estimate of molecular dimensions from data provided by that theory, to define exactly what is meant by the angle of contact, and interestingly enough, he examined the variation of that angle for metals amalgamated with mercury. He calculated the range of the cohesive forces to be 4×10^{-9} in., or one Angström. He developed the drop-weight method of measuring surface tension and took issue with Laplace on the origin of the surface forces, knowing, indeed, that repulsive, as well as attractive, forces were involved.

It is scarcely necessary to mention the contribution of Lord Rayleigh to the subject of surface tension—his method of measuring dynamic tension, which is now universal, and his estimation of the size of molecules by using Davy's experiment to determine the amount of oil required to stop the movements of camphor. He also investigated the theory of surface forces and showed how the theories of Laplace and of Young had to be supplemented by Gauss's hypothesis of surface potential-energy. Experimentally, he achieved a triumph in describing how he succeeded in spreading water on clean mercury.

Dewar examined the properties of soap films in detail, revealing their laminated structure and determining many properties such as their permeability to gases.

Another interesting phase of surface chemistry and physics is to be observed in the development of our ideas of heterogeneous catalytic action. Davy in his experiments on the miner's safety lamp showed that neither flame nor explosions would pass along narrow metallic tubes. In the case of explosions, we can understand the breaking of the wave front by the tube systems; but in the propagation of flame two factors have to be considered, namely, the loss of heat in the walls, and the catalytic activity of the walls. We now have evidence that in a number of cases in the propagation of flame there is an advancing front of free radicals and of hydrogen atoms. The power of metals to combine hydrogen atoms catalytically can be demonstrated in many ways. We may note that in Faraday's experiments on electrolysis the hydrogen atoms liberated at the electrode combine and come off as molecules, especially noticeable on platinum, where the over-potential is low. Later, the fact that the expected volumes of electrolytic gas were not always obtained led Faraday to his important investigation on the power of metals to induce the combination of gases. He propounded a theory of catalytic action which still has many protagonists. He regarded the gases as condensed on the surface by what we now call Van der Waals's or dispersive forces, a type of condensation used later by Sir James Dewar in utilizing cool charcoal for obtaining high vacua.

Faraday writes in his notebook, November 25, 1833, "Think this (surface adsorption) a subject of great consequence, for I am convinced that the superficial actions of matter and the actions of particles not directly or strongly in combination are becoming daily more and more important in chemical as well as in mechanical philosophy". Again, "Immerse the blade of a knife in water, on drawing it out it will not be equally wet, but the water will appear in particles or run into globules. But suppose you dip in the platina plate cleaned as directed, it comes out uniformly wet."

It is now possible to examine the primary products of catalytic actions by means of the mass spectrograph, one of which has been made in the Institution and is in use for this purpose. It was in the lecture theatre of the Institution that Sir J. J. Thomson gave the first account of his discoveries concerning the parabolas described by positive ions in a field, an effect from which Aston developed the mass spectrograph.

Surface chemical reaction was noted by Rumford, who showed that a pellicle of gold would develop at the interface between a gold chloride solution and ether, or on an impregnated carbon disk, on illumination; and Faraday carried out similar experiments.

We now have a more sensitive method of measuring these reactions at liquid surfaces by means of the phase boundary potential changes caused in chemical reaction.

In another field, I would like to refer to the light-scattering experiments of Tyndall, and the theoretical examinations by Lord Rayleigh which have led directly to the modern method of measuring the size of colloid particles, especially developed by Debye.

The work of Sir William Bragg on X-rays has led to the possibility of examining colloidal material by this method. It is possible from the X-ray spacings of solutions to obtain some of the dimensions of colloid particles such as the molecule of ovalbumin.

The subject of the physics and chemistry of surfaces, although only a small brick in the great edifice of science, yet contains within itself many interesting and wonderful things, and our present knowledge of what is sometimes regarded as a very recent development is, indeed, part of the heritage into which we enter when we work in the Royal Institution and in its Davy Faraday Laboratory.

It will not be denied that the Institution of Rumford and of Davy has not only pursued the objectives which the creators desired, but also has contributed continuously to the advancement of knowledge. We must now ask ourselves the question whether an institution founded one hundred and fifty years ago has a place or function in the Britain of to-day and to-morrow.

During the last decade, we have witnessed the gradual disappearance of an individualistic society. This change has been reflected in many aspects of science. We note the growth of the concept of the planned mass attack on specific problems by the co-ordinated efforts of teams of workers. One does not venture even to guess at the number of scientific workers engaged on the Manhattan project or on penicillin. There is much to be said for such developments in a technological sphere, especially as we are living in a world of fast dwindling assets:

> But where shall wisdom be found?
> And where is the place of understanding?
> It cannot be gotten for gold
> Neither shall silver be weighed for the price
>   thereof.
> Yea, the price of wisdom is above rubies.

In the exploration of uncharted seas which are lit by no beacon light, but illumined only by the inner light and imagination in the mind of the explorer, it is still, and must ever be, the individual. The characteristic, individualistic attitude of the workers in the Royal Institution can thus find a place in modern society. Indeed, if such places did not exist, we should have to create them in order not to lose our souls. How best to preserve its freedom of thought, and thus serve most effectively both science and the State, is an ever-recurring problem.

It is certain that Michael Faraday, whose name is most naturally associated with this Institution, would be the first to object to its conversion into a museum to perpetuate his memory. He would, we feel sure, prefer to see it as a live and active centre of research. Indeed, he could have no better memorial than a laboratory to which people interested in Nature and with inquiring minds could work. Some idea such as this must have entered the mind of Ludwig Mond, when he conveyed in 1896 the Davy Faraday Research Laboratory to the Royal Institution.

To solve this problem in all its functional and economic aspects, there is still much to do, and we of this generation must see to it that we do not, in spite of difficulties, fail to give an account of our service and stewardship.

I cannot do better than terminate with the words of Sir Humphry Davy:

"Let not the countrymen of Bacon, of Newton and of Boyle neglect those pure springs of knowledge from which these great men drew such copious supplies both for profit and for glory, and let it not be forgotten that science has its moral and intellectual, as well as its common aims, and its object is not only to apply the different substances in nature for the advantage, comfort and benefit of man, but likewise to set forth that wonderful and magnificent history of wisdom and intelligence which is written in legible characters both in the heavens and on earth."

OBITUARIES

Prof. T. S. Patterson

Thomas Stewart Patterson was born in Greenock in 1872. After his early education at Merchiston Castle School, of which in later years he became a governor, he studied chemistry at the Andersonian College, Glasgow, under Dittmar, and then proceeded to Heidelberg, where he graduated as Ph.D. in 1896 with a thesis on iodoso- and iodo-benzaldehyde. In this romantic city by the Neckar he fell under the spell of that man of genius, Victor Meyer, who was then at the height of his transcendent powers. After a year in Birmingham as the first Priestley scholar, he became a member of the staff of the Yorkshire College, Leeds, before he returned to Glasgow in 1904 as senior assistant to the professor of chemistry in the University, being afterwards promoted to Waltonian lecturer and lecturer in organic chemistry. He graduated as D.Sc. both in London and Glasgow, and in 1919 he became the first holder of the Gardiner chair of organic chemistry at Glasgow, which he occupied with distinction until his retirement in 1942. His services to the University were honoured by the conferment upon him of the degree of LL.D. in 1943. During his tenure of the chair he played his full share in administration, since he served for some years as dean of the Faculty of Science, and as a member of the University Court. The welfare of his students, with whom he was very popular, made at all times a great personal appeal to him, and he was one of the founders of the Alchemists' Club, which served so much to broaden their outlook.

It was one of the two pioneers of stereochemistry in Great Britain, namely, Prof. Percy Frankland, who attracted him to that particular branch which deals with the connexion between optical rotatory power and chemical constitution. His first paper on the effect of chloroacetyl groups on the rotation of methyl and ethyl glycerates and tartrates was published in 1898, and was followed by a long series of thirty-eight communications on the influence of solvents and other factors on the rotation of optically active compounds. Those researches, which were prosecuted in elaborate detail and with great regard for accuracy, displayed at once originality and experimental skill of a high order, and gained for him the reputation of being the leading authority on this fundamental theme. True it is that his early polarimetric measurements were confined to light of one wave-length only, and for that reason his deductions were occasionally somewhat lacking in conviction. But the valuable work of Pickard and Kenyon on optically active secondary alcohols attracted his attention to the necessity of extending his investigations to take account of results with lights of varying wave-lengths, while the usefulness of the characteristic diagram of Armstrong and Walker in correlating optical rotation data was also stressed. Even then, his results were occasionally difficult to interpret; the problem at issue was indeed a most evasive one. It was accordingly understandable that discussions with workers in the same field, such as Walden, Lowry and Pope, assumed at times a somewhat acrimonious trend. Well indeed might Patterson have exclaimed with Alan Breck, "And O, man, am I no a bonny fighter ?"

Other topics investigated dealt with optical superposition, and with the polarimetric study of intramolecular re-arrangement. The latter topic yielded some interesting results. Thus, the *syn-* form of benzaldoxime was shown to have a much more pronounced effect on the numerical value for the rotation of a solution in ethyl (+) tartrate than had the corresponding *anti*-oxime, so that the velocity of re-arrangement could be observed with ease. While other compounds were shown to display a similar transformation, it was noted that the purer the ethyl tartrate the more slowly did the interchange occur. Reference might also be made to his 'green' ethyl tartrate. 'Back to Pasteur' was the note struck in his final experimental contributions with Buchanan on the crystalline forms of various sodium and potassium tartrates. It always gave Patterson pleasure to show visitors to his laboratory those large crystals where the hemihedral facets stood out so beautifully.

No account of Patterson's work would be complete without reference to his scholarly writings on the history of chemistry. Those included aspects of Helmont, Beguin and Leblanc; most important was his elaborate critical survey of Mayow on respiration and combustion. In his later years he was more particularly interested in Paracelsus.

Patterson spent his vacations mainly on the Firth of Clyde, for he was an expert yachtsman, and a member of the Clyde Corinthian Club. His death on February 14 of this year will have recalled to his many friends the memory of a very upright and lovable man. Alex. McKenzie

Mr. Birrell Russell

On March 4, after making an adjustment at the top of the apparatus on which he was working, Birrell Russell slipped in some unexplained way and fell 33 ft. to the ground. He received very severe head injuries and died without regaining consciousness in the early morning of March 8.

Russell was a senior member of the staff of the Atomic Energy Research Establishment, Harwell, having been promoted to principal scientific officer in 1947. He graduated at Glasgow in 1933, taking first-class honours in mathematics and natural philosophy (second place for the year). He then did two years research work, as Houldsworth Research Scholar, on the diffraction of proton beams. From there, he went to the National Physical Laboratory, taking up radio research, and was transferred in 1937 to the Royal Aircraft Establishment, where he worked under Dr. A. C. Bartlett on very high frequency radio for aircraft. In 1940, he was moved to the Telecommunications Research Establishment, then at Worth Matravers, and remained with that Establishment throughout the War.

Russell's work at the Telecommunications Research Establishment was mainly on aerials for aircraft radar. He worked first on aerials for the early version of A.I., the radar device used by fighters to track down enemy aircraft in the dark. Later, he devised direction-finder aerials to enable our long-range fighters to home on to enemy fighters fitted with A.I. Thus he was able to develop a device which enabled our fighters to single out and destroy enemy night-fighters. This was put into operational use with excellent results in the British large-scale bombing offensive. At the end of the War, Russell worked on centimetre-wave aerials and was the author (or part author) of two papers on this subject in the *Journal of the Institution of Electrical Engineers.*

In the summer of 1946, Russell transferred to Harwell, where he was one of the first residents on the site. He was set the problem of isotope separation by the method of gaseous thermal diffusion. As a result of his work, he was able to set up a plant for the production of oxygen-18, enriched from its normal concentration in atmospheric oxygen up to about 20 per cent. This plant had been erected and tested, and was due to start production on March 7. The product was to be sent to the Medical Research Council for use as a non-radioactive tracer in important medical and biological work. It was after making a final adjustment to a water relay in preparation for the production run that the accident occurred.

Russell had considerable experience in the supervision of the work of junior staff and was in charge of a group working on various problems connected with isotope separation in the gas phase. He was a very energetic and capable experimentalist who had his heart in his work, and Harwell and the world of science generally have suffered a severe loss in his premature death. He leaves a widow and two small children.

H. W. B. Skinner

We regret to announce the following deaths:

Sir Thomas Hill Easterfield, K.B.E., during 1899–1919 professor of chemistry in the Victoria University College, Wellington, New Zealand, and director during 1919–33 of the Cawthron Institute, on March 1, aged eighty-two.

Sir William Hale-White, K.B.E., of Guy's Hospital, London, president in 1922–23 of the Royal Society of Medicine, on February 26, aged ninety-one.

Mr. James Hornell, known for his studies of primitive boats, on February 24, aged eighty-three.

Sir Archibald Page, formerly chairman of the Central Electricity Board, and president in 1927–28, and honorary member, of the Institution of Electrical Engineers, on March 7, aged seventy-three.

NEWS and VIEWS

Agricultural Research Council: Dr. W. K. Slater

With the approval of the Lord President of the Council and after consultation with the president of the Royal Society, the Agricultural Research Council has appointed Dr. W. K. Slater to be its secretary, in succession to the late Sir John Fryer, as from May 1. The Minister of Agriculture and Fisheries has agreed at the request of the Agricultural Research Council to release Dr. Slater from his present duties as a senior education and advisory officer in the National Agricultural Advisory Service. Dr. Slater was educated at the Oldham Hulme Grammar School and at the University of Manchester, where he graduated in 1914. In 1922 he joined the team working under Prof. A. V. Hill in the Department of Physiology, Manchester, and later followed Prof. Hill to University College, London. During the next six years, Dr. Slater held Junior and Senior Beit Memorial Medical Research Fellowships, and carried out a series of investigations on the anaerobic phase in muscular contraction and on the general phenomenon of anaerobiosis in animals. In 1928 Dr. Slater joined the staff of the Dartington Hall Trustees to set up a research laboratory and supervise the scientific aspects of their wide-scale experiments in rural economy, and later he was placed in charge of the administration of the agricultural departments of the Trust. Although personal research work was not possible, the laboratory at Dartington Hall under Dr. Slater's general supervision co-operated extensively with the research institutes on a wide range of problems, and did valuable work on the control of potato blight and on cobalt deficiency effects in sheep. In 1942 his services were loaned to the Ministry of Agriculture and Fisheries to assist the late Sir John Fryer in connexion with the Agricultural Improvement Council, and when Sir John became secretary of the Agricultural Research Council, Dr. Slater followed him as secretary of the Agricultural Improvement Council.

J. W. Döbereiner (1780–1849)

Born at Hof in Bavaria, Johann Wolfgang Döbereiner began as a pharmacist's apprentice in 1794, and later practised pharmacy at Dillingburg, Karlsruhe and Strasbourg, where he set up as a manufacturer of chemicals. For a time he conducted an institute for teaching practical chemistry; then he joined a textile company and set about improving dyeing processes. The Napoleonic wars ruined him; but he was fortunate to come to the notice of Goethe, who obtained for him a professorship at Jena, where he remained from 1810 until he died on March 24, 1849. Döbereiner is credited with improving (and giving a correct explanation of) the making of vinegar; but he is best known for directing attention, in 1817, to the fact that the atomic weight of strontium is the mean of those of calcium and barium. He also noticed the same relationship with other 'triads' (chlorine, bromine, iodine; sulphur, selenium, tellurium). Döbereiner's 'triads' passed unnoticed at the time, and only after Newlands' 'law of octaves' and Mendeléef's Periodic Law had been enunciated some fifty years later did Döbereiner's work attract attention. It is also not generally known that he introduced, in 1832, the method of preparing oxygen from potassium chlorate by heating in the presence of manganese dioxide.

Government Grants for Research and Development

In the Supplementary Civil Estimates for the year ending March 31, 1949, aggregating £221,471,574, there are various sums for scientific research and like purposes in Great Britain. The additional £1,950,000 for development and welfare (Colonies, etc.) includes a further £450,000 for research schemes, making a total for the year of £750,000. An additional Treasury grant-in-aid of £600,000 is required to meet liabilities maturing in respect of capital grants already approved to the Universities and Colleges of Great Britain. Of the additional £152,000 gross for the Department of Scientific and Industrial Research, £86,000 is required for grants to students and others engaged in scientific research, £5,000 for grants to research associations and other bodies engaged in industrial research to match increased industrial contributions, £34,000 for extra-departmental research work, £16,000 against salary revision and £11,000 for salary revision at the Geological Survey of Great Britain and the Museum of Practical Geology. Appropriations-in-aid and certain anticipated savings reduce the supplementary estimate to £81,000 net. The Ministry of Supply requires a further £1,760,000 net for research and development, of which £360,000 is for research and development work carried out by industry, and £2,150,000 gross for plant, equipment, stores and materials for Government establishments. Among miscellaneous items are grants-in-aid of £6,000 for the Institute of Public Administration, £12,000 for the Imperial Institute, £20,000 for the British Institute of Management and £25,000 to the Council of Industrial Design for preparatory work for the Festival of Britain, these last falling under the Board of Trade vote. The supplementary estimate for the Scottish Home Department includes a grant-in-aid of £20,000 for the National Trust for Scotland.

Human Skull from Fontéchevade, France

Two years ago it was reported that part of a human skull had been discovered at Fontéchevade in the Charente district of France. The importance of this discovery is related to its antiquity, for according to the preliminary account it was found in association with implements of Tayacian type and with remains of the 'warm' fauna which preceded the Würm glaciation. The skull, therefore, appears to antedate Neanderthal man and to represent the most ancient human remains (stratigraphically well documented) so far discovered in France. A note on the specimen by H. V. Vallois has recently appeared in *Comptes Rendus* of the Paris Academy of Sciences (February 14). Unfortunately this note is very brief, and is illustrated by only one outline drawing of the lateral view of the skull. The latter consists of the greater part of the parietal bones and approximately the upper two-thirds of the frontal. These bones are unusually thick, and in this feature are comparable to the Swanscombe skull (which dates from the middle Acheulean period). It appears also that, so far as some of their main characters are concerned, they show no evidence of Neanderthal affinities. The supra-orbital part of the frontal bone is unfortunately missing; but the position of the upper margin of the frontal air sinus is indicated, and from this it appears certain that the curvature of the forehead region of the skull must have conformed closely to that of *Homo sapiens*. In other words, there is no evidence of a heavy supra-orbital torus of Neanderthal type. So far as this rather meagre evidence goes, the Fontéchevade skull confirms the evidence of the Swanscombe skull from the Thames valley that Neanderthal man was antedated in Europe by a type of man which approximated in cranial characters more closely to *Homo sapiens*. It is to be hoped that a full and well-illustrated account of the Fontéchevade skull will not be long delayed.

Significance of Complementarity in Physics: *Dialectica*

The word 'complementarity' was originally introduced by Niels Bohr to express one of the most fundamental ideas in quantum theory, that we cannot simultaneously measure both the position and velocity of a particle—the more we know about one, the less we can know about the other. It is in this sense that we speak of our knowledge of the two quantities as complementary. But the idea is capable of wide generalization, since position and velocity (or momentum) are not the only pairs of 'conjugate observables'. Indeed, it is no exaggeration to say that a proper understanding of this principle is the greatest single contribution of modern physics to philosophy. The editorial board of *Dialectica*, a quarterly journal devoted to a review of the philosophy of knowledge, has done a public service by assigning the whole of the current issue (vol. 2, No. 3-4, published in Neuchâtel, priced 4.80 Swiss francs and obtainable from H. K. Lewis, 136 Gower Street, London, W.C.1) to a study of the single topic of complementarity.

The present issue is the more remarkable because no less than five Nobel prizewinners contribute to it. Pauli writes the editorial and briefly reviews the various subsequent contributions; Bohr describes the idea itself; de Broglie shows how it relates to the distinction between a complete unit (for example, a helium atom) and the individuality of its component parts (for example, electrons and nucleus); Heisenberg, to whom, of course, we owe the precise formulation of the uncertainty relations which lie at the heart of the idea, describes the progressive development of the concept; and Einstein restates one of his earlier arguments that present quantum theory is incomplete and requires to be supplemented, or replaced, by a new theory in which the state of any physical system is independent of any possible observations which might be made on it. Applications of the idea itself in the fields of biology and thought processes, and a possible way round some of the acknowledged difficulties in present-day quantum theory by the use of a non-Aristotelian three-valued logic in which statements may be either true, false or indeterminate, make up a most interesting volume.

Archiv für Meteorologie, Geophysik und Bioklimatologie

A NEW Austrian journal, *Archiv für Meteorologie, Geophysik und Bioklimatologie*, began publication last September under the editorship of Dr. W. Mörikofer (Davos) and Prof. F. Steinhauser (Vienna). It is divided into two series, (*A*) meteorology and geophysics, and (*B*) general and biological climatology (including their agricultural and micro aspects) and radiation phenomena. The issues will be of variable size, published (not at regular times) according to the material available; they will be combined into (probably annual) volumes each of about 400 pages. One part of each series appeared in September, (*A*) of 141 pages, price £1 5*s*. 6*d*., and (*B*) of 114 pages, price £1 3*s*. 0*d*. The first issue of series *A* contains seven articles and one note, all in German, but with abstracts in English (not always grammatical) and French. The authors are Courvoisier (barometric pressure variations), Defant (internal tidal waves), Reuter (heat balance of snow cover), Burkard (arctic ionosphere), Bouët (pluviology), Eckel (energetics of water-mixing), Toperczer (methodicity of land magnetic surveying), and Götz (note on auroral photography). The paper and printing are up to the known high standard of the publishing firm of Springer (now in Vienna), but an annoying and unnecessary inconvenience and waste of time are imposed on the reader by the fact that the pages are uncut; this practice has long been abandoned by many publishers, and it is difficult to see why any should continue it.

Journal of Geophysical Research

FROM March 1949 the journal *Terrestrial Magnetism and Atmospheric Electricity* will appear under the new title *Journal of Geophysical Research*. The change of name marks the transfer of editorship from Dr. J. A. Fleming to Dr. Merle A. Tuve, who is also a successor of Dr. Fleming in his other former capacity as director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington. Dr. Fleming, who has been associated with the journal almost since its inception by L. A. Bauer in 1896, becomes honorary editor; the journal, aided by a subsidy (which will be continued and somewhat increased) from the Carnegie Institution of Washington, was published on Dr. Fleming's own financial responsibility for more than twenty years, and he gave to it generously also of his time and effort. It is hoped that other organisations, both national and international, will assist the journal financially in future, and that, with the aid of a page charge in cases where contributors' papers are sponsored by institutions, it will be possible, despite the great increase in costs, to continue to publish the journal at the very moderate subscription-rate hitherto charged, namely, 3 dollars 50 cents for the four numbers per year. The change of title indicates a widening of the scope of the journal, though the scope has long transcended the limits implied by the title now discontinued. All who know the journal in its old form will wish it success under its new title and auspices.

Indian Association for the Cultivation of Science

THE annual report for the year 1947–48 of the Indian Association for the Cultivation of Science covers the year ending March 31, 1948, and in addition to the usual financial statement and balance sheet there are appended lists of books added to the library during the year, periodicals received by subscription or exchange, members of the Council and of the Committee of Management and a report on the scientific work of the Association. In the latter Prof. K. Banerjee reports on R. K. Sen's continued study of the extra Laue reflexions of benzil, while over-exposed Laue photographs of pyrene have been taken by M. N. Dutta at 30–100° C. which show that the intensities invariably increase with temperature for all the different spots. M. Ganguly has found that very clear reflexions of the low-angle scattered X-radiation can be obtained by a crystal which is very slightly mis-set from the position for reflecting the direct beam. B. S. Basak has undertaken the complete determination of the structure of phenanthrene crystals by the Fourier analysis method, and, with A. K. Rai Choudhury, has made X-ray diffraction studies of beryllium – aluminium and tin – aluminium systems. X-ray studies of samples of Indian coals have been made by N. N. Gupta, and the mechanism of the formation of jutellite, a plastic from jute waste, is being studied by J. C. Maitra. B. K. Banerjee has continued to study the dispersion of metals and salts in glass, and Dr. A. Bose has undertaken a systematic investigation of crystal paramagnetism to determine whether group structure formed by the internal fields in the solid state persists in solution. A. Dutta has undertaken a systematic study of the magnetic and electric properties of semiconductors, such as tungstenite.

Prof. S. C. Sirkar reports on B. M. Bishui's investigation of the polarization of Raman lines of ethylene dibromide in various solvents and on his further work on the Raman spectra of 1 : 1-dichloroethane. The Department of Physical Chemistry only commenced work on October 1, 1947, but Prof. S. R. Palit reports that investigation has already been initiated on several problems in polymerization, on surface-active agents and metallic soaps in organic solvents with reference to solubility, surface tension, electrical and similar properties, on the kinetics of halogenation of sodium acetate in glacial acetic acid, sodium propionate in propionic acid, etc. Potentiometric studies in non-aqueous media have also been undertaken, as well as the synthesis of styrene, methyl methacrylate, etc., for high-polymer studies.

New York Academy of Medicine

Now that Great Britain is committed to the National Health Service, it is interesting to find that neither the retiring president of the New York Academy of Medicine, nor its incoming president, nor the Academy itself, can support, at present at any rate, compulsory national medical insurance in the United States. Dr. George Baehr, the retiring president, referred, in his valedictory address to the Academy delivered on January 6 last, to the report, published in 1947, of the four-year study made by the Academy's Committee on "Medicine and the Changing Order". He reminded his audience that the Academy recognizes the need for changes; but, after serious consideration, has decided definitely to oppose compulsory national medical insurance at the present time. Instead, it considers that a medical service with prepayment of fees can be attained more efficiently and with much less risk by Federal grants to State and local areas; such a service would be adaptable to the varying needs of the States and their political subdivisions and also to rural and urban areas. The Academy favours voluntary efforts because they are more flexible and experimental; but it should consider earnestly the effects upon medical practice, education and research of the modern prepayment schemes. A new Committee of Medicine and the Changing Order has been appointed to consider this question. Dr. Baehr also referred to the success of the new (twelfth) Microbiological Section of the Academy and to the great services performed by the Library, which is one of the largest in the world.

Dr. B. P. Watson, the incoming president, has spent most of his life as a teacher and thus becomes the head of an educational institution devoted to the needs of the medical profession, the layman and the community as a whole. He reminded his audience that present-day medicine is the result of a slow process of evolution, in which the scientific approach to medicine has played a part since "the beginnings of recorded time". This evolution is the result of the interplay between research workers, reactionaries opposed to change, extremists who wish to proceed too quickly and the backbone of the profession, composed of steady, experimental thinkers who await the results of experiments and give the individual and the community the best that the profession can offer. Dr. Watson felt that any plans for a compulsory national health insurance that could be instituted now would lower the quality of medical care provided and would give the individual medical practitioner a task that he could not perform with satisfaction either to himself or to his patients. The Academy recognizes the need for improvement in the distribution of medical care, so that everyone can have it, but it pleads for continuing study and development, so that the best medical service and better teaching and research may result. In the course of his address, Dr. Watson discussed medical education, emphasizing, as the Goodenough Report on British Medical Schools has done, the teaching of principles, the integration of details learnt and the infusion into the teaching of more of the philosophical thought bequeathed to us by the past and nowadays "forgotten in the hectic pursuit of each newly-discovered fact".

Forestry in Uganda : Report for 1947

The annual report of the Forest Department of Uganda Protectorate for the year ended December 31, 1947, has recently been published (Entebbe: Govt. Printer, 1948; price 2*s*. 6*d*.). This report of 49 pages commences, as a number of recent forest reports from Africa have done, by a declaration of Government forest policy, which is on the familiar lines that have often been referred to in *Nature* in connexion with forestry notes. The forest policy during 1947 was considerably implemented as the report shows; it was to some extent the result of the Development Plan for Uganda put forward by Dr. E. B. Worthington which was approved by the Legislative Council during the year. This plan provided for the Forest Department receiving the sum of £205,500 to be spent in the ten years 1947–56 on expansion and development schemes, and this sum was to be in addition to the ordinary normal recurrent expenditure. As the amounts to be spent from this allocation for work only included soft-wood timber plantations, fuel planting-schemes, and research and investigation, hardwood-timber planting schemes apparently are to be covered by normal recurrent expenditure. This appears to be a pity, since it would seem that the indigenous hardwoods of Uganda may be neglected. Anti-malaria plantations were formed, at the request of the medical and health authorities, and the Department meant to clear-fell and replant them at intervals as an addition to the fuel supplies; but the health authority has been against clear-felling, and the plantations will be managed on the selection felling basis. The reservation of more forest has been proceeding, but it is pointed out that the distribution of forest is not all that could be wished for, particularly in parts of the Eastern Province; nor is it hoped to be able to make further reserves, and this leaves one with village forests as the alternative. It is noteworthy in this report that the importance of the savannah forest has now come to be understood. In fact, it is stated that the greater part of Uganda is covered by this type of forest growth, and it is from the savannah rather than from closed forest that the demands of people for forest produce are chiefly met. It is a welcome sign that the formerly neglected savannah or 'bush' is now coming into recognition and, even more, that it is to be classified as 'forest'.

Hormones and 'Drop' of Apple Fruits

The abscission or dropping of apple and other fruits after fertilization is sometimes a valuable natural method of thinning the crop, but is often the source of much loss of fruit. L. C. Luckwill has studied the relation to this 'drop' of a hormone occurring in apple seeds (*J. Hort. Sci.*, 24, No. 1, 32; June 1948). He devised a quantitative method of measuring the hormone extract by treatment of tomato ovaries (*ibid.*, 19) and was able to show that the appearance of the hormone in the seed coincided with cessation of the post-blossom drop. In the variety Beauty of Bath, the hormone appeared 25–30 days after petal-fall. Seeds of nearly ripe apples had little hormone, and its disappearance corresponded with the occurrence of pre-harvest dropping of the fruit. Moreover, seeds from 'June-drop' fruitlets of two other varieties contained much less hormone than those of fruits which remained on the tree. This hormone can be extracted from the seeds with boiling water, and though it stimulates the development of tomato ovaries, it does not appear to initiate fruit growth in the apple. It does, in fact, appear to be concerned chiefly with the control of fruit drop.

Markle Foundation Scholarships in Medicine

Under the plan begun in 1948 by the John and Mary R. Markle Foundation to assist qualified men and women wishing to remain in academic medicine, thirteen men of science have been awarded grants of 5,000 dollars a year, for five years, to maintain them in the medical schools of the United States and Canada in which they now hold faculty appointments. So far, twenty-nine such awards have been made. The thirteen new recipients, their fields of interest, and place of present appointment are as follow: Dr. Francis P. Chinard (University of California and Johns Hopkins), clinical chemistry and physiology, at Johns Hopkins University; Dr. Don W. Fawcett (Harvard), microscopic anatomy, at Harvard Medical School; Dr. Allan V. N. Goodyer (Yale), internal medicine and cardiovascular disease, at Yale University; Dr. John B. Graham (Cornell), pathology, at the University of North Carolina; Dr. John D. Green (Oxford), anatomy and physiology, at Wayne University College of Medicine; Dr. George Watson James, III (Washington and Lee University), internal medicine and physiology, at the Medical College of Virginia; Dr. Ralph Jones, jun. (West Virginia

University and University of Pennsylvania), clinical therapeutics, at the University of Pennsylvania; Dr. George E. Moore (University of Minnesota), surgery and onocology, at the University of Minnesota; Dr. C. Barber Mueller (University of Illinois and Washington University), surgery and biochemistry, at Washington University; Dr. George W. Schwert, jun. (University of Minnesota), physical biochemistry, at Duke University; Dr. Beverly T. Towery (Vanderbilt), internal medicine and endocrinology, at Vanderbilt University; Dr. W. Clarke Wescoe (Cornell), pharmacology, at Cornell University; Dr. Donald R. Wilson (Oxford and McGill), internal medicine and endocrinology, at the University of Alberta.

Scholarships in the United States for British Students

THE Colorado School of Mines is offering a scholarship to a male student from England for the academic year 1949–50. A separate offer is being made for Scotland. The scholarship is worth 425–475 dollars and is renewable for a maximum period of four years. Further particulars and application forms may be obtained from the Assistant Cultural Officer, U.S. Information Service, American Embassy, 5 Grosvenor Square, London, W.1, or from the secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1, with whom application forms must be lodged by May 1.

Harvard University announces that a fellowship, worth 2,000 dollars, provided by Mrs. Frank Knox in connexion with the Frank Knox Memorial Foundation, will be made available to enable a student from the British Isles to spend the academic year 1949–50 at Harvard. The fellowship is open to students of all stages; but preference will be given to candidates who have graduated or are about to graduate in Great Britain or Ireland. There is no form of application. Further particulars can be obtained from the Secretary, Association of Universities of the British Commonwealth; applications must be completed by April 9.

International Conference on Science Abstracting

AN International Conference on Science Abstracting is to be held by Unesco in Paris during June 20–25. All Unesco and United Nations Member States will be entitled to nominate three delegates. Representatives have also been invited from the specialized agencies of the United Nations and from the appropriate international organisations such as the International Scientific Unions, the International Federation for Documentation and the International Organisation for Standardization. It is expected that the directors and editors of many of the most important abstracting services will be present at the Conference. Unesco will be glad to receive applications from persons other than officially appointed representatives who wish to attend as observers. The purpose of the Conference will be: "to consider and take action to improve and develop abstracting services for the natural sciences, both pure and applied, and to consider methods of increasing their usefulness to scientists, with regard at the same time to the related problems of indexing and accessibility of the recorded publications".

The Physical Society: Seventy-fifth Anniversary Celebrations

THE celebration of the seventy-fifth anniversary of the Physical Society will take place on March 21. A conversazione will be held in the Royal Society's Rooms, Burlington House, Piccadilly, London, W.1, during 8–11 p.m., with the president, Prof. G. I. Finch, and Mrs. Finch as hosts. Admission is by ticket only. Earlier in the day, at 5 p.m., the Guthrie Lecture will be delivered by Prof. A. O. Rankine at the Royal Institution, 21 Albemarle Street, London, W.1, the subject being "Experimental Studies in Thermal Convection".

Announcements

MAJOR-GENERAL CYRIL LLOYD, director of Army Education, has been appointed administrative director of the Department of Technology of the City and Guilds of London Institute as from October 1, in succession to Lieut.-Colonel W. French.

A DAVID ANDERSON BERRY Silver-gilt Medal with a sum of £100 will be awarded in 1950 by the Royal Society of Edinburgh for work on the therapeutical effect of X-rays on human diseases. Applications (with copies of accomplished work) must be sent to the General Secretary of the Royal Society of Edinburgh, 22 George Street, Edinburgh, 2, by March 31, 1950.

THE Arnold Gerstenberg Studentship for 1950 is open to students in the University of Cambridge who have obtained honours in the Natural Sciences Tripos and who went into residence not earlier than 1944. The Studentship will be awarded for an essay which must be submitted before May 1, 1950; full details may be obtained from Mr. R. B. Braithwaite, King's College, Cambridge.

DR. K. C. EDWARDS, reader in geography, has been appointed professor of geography, and Dr. E. J. W. Barrington, reader in zoology, has been appointed professor of zoology in the University of Nottingham. Both these chairs have just been established.

THE British Institute of Management will hold the fifty-third in the 'Oxford' series of Management Conferences at Cliftonville during May 5–8. The form of the Conference has been altered, and the general purpose is to obtain a consensus of opinion among practising managers on certain fundamental and possibly controversial questions relating to the development of management, for the guidance of the Institute. Applications for tickets and all correspondence should be addressed to the Director, British Institute of Management, 17 Hill Street, London, W.1.

A BOOKLET entitled "The Tilgate Story" has been issued by Messrs. F. W. Berk and Co., Ltd., of Commonwealth House, 1–19 New Oxford Street, W.C.1. This deals in a general way with the firm's research work on soil sterilization, deficiencies of soil nutrients, mercurial seed dressings, mercurized turf sand for the control of moss, and other mercury and copper fungicides and insecticides.

Mathematical Tables and Other Aids to Computation is a quarterly journal which is published and subsidized by the U.S. National Research Council. Not only is it running at a loss, but also costs are rapidly mounting. A substantial increase in the number of subscribers is necessary in order to avoid either increasing the price or reducing the size of the journal. The subscription-rate is 4 dollars per year, and full details may be obtained from the National Research Council, 2101 Constitution Avenue, Washington 25, D.C. In Great Britain the rate is 25*s*., and the agent is Scientific Computing Service, Ltd., 23 Bedford Square, London, W.C.1.

LETTERS TO THE EDITORS

Heavy Nuclear Splinters

An extensive analysis[1] of the energetic disintegrations produced in the silver and bromine nuclei of nuclear emulsions exposed to cosmic radiation indicates that the emitted particles, consisting of α-particles, protons and neutrons, generally escape from the nucleus after the excitation energy has been statistically shared among the constituent nucleons.

The disintegration process is then analogous to the evaporation of molecules from a drop of liquid. Occasionally, however, stars are observed[2-4] in which highly charged nuclear splinters are ejected from strongly excited nuclei before equilibrium has been attained. From a total of six thousand stars, we have observed two examples in which we can identify such heavy fragments. These events are not so rare as this might imply, since their tracks can only be identified when they have a considerable length in the emulsion. The two stars were obtained in 'sandwich' emulsions exposed on the Jungfraujoch (3,500 m.).

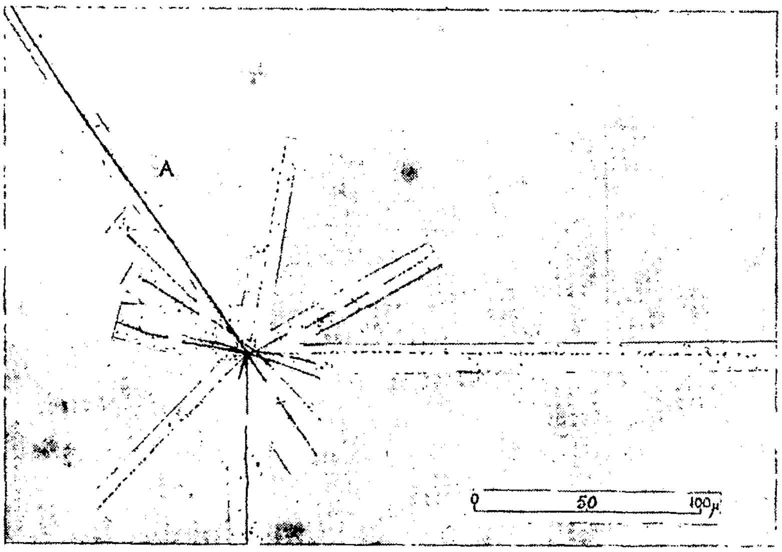

Fig. 1. Complete disintegration of a bromine nucleus, with emission of a heavy fragment of $Z = 11 \pm 1\ e$. Observer: Miss J. Steward

Fig. 1 is a photomicrograph of a large 'double star' in which at least eighteen charged particles are emitted. The heavy track *A*, $195\,\mu$ long, tapers towards the end of its range due to a gradual loss of charge as the nucleus picks up electrons. The 'thin-down length' is about $65\,\mu$, indicating[5] a charge of $11 \pm 1\ e$. The energy of the particle producing this track is estimated as 325 ± 50 MeV., and its momentum as $3{,}500 \pm 400$ MeV./*c*.

A second heavy particle emitted in this event either splits up spontaneously, or disintegrates a nucleus, after traversing $6\,\mu$ of emulsion. Assuming the former, its charge is at least $6\ e$, as two protons and two α-particles are emitted in this secondary event. Since, in addition, eight protons and five α-particles leave the parent nucleus, the charge of the latter must have been at least $35 \pm 3\ e$. It seems likely, therefore, that this event represents the complete disintegration of a bromine nucleus.

The background grain-density is very high in this plate, so the fainter proton tracks have been retouched in the photograph to make them easily visible. The emulsion contains $5\,\mu$ layers of pure gelatine, causing discontinuities in the tracks where the charged particles pass through these sandwich layers.

The second disintegration (see Fig. 2) was observed in an emulsion containing thin layers of lead phosphate, and coated on a 250-μ acetate base. This film was one of a pile, and the heavy particle from the star penetrates the last three films of the stack. Its equivalent range in emulsion is at least $2{,}000\,\mu$. A comparison of its δ-ray frequency with that along the track of a fast α-particle of known energy indicates that it is of charge $5 \pm 1\ e$ and hence energy 350 ± 100 MeV. and momentum $2{,}500 \pm 600$ MeV./*c*.

If we assume that the energy of the emitted neutrons is about equal to that of the protons, then the excitation energy required to produce these stars is estimated as at least 700 MeV. in the first case and 500 MeV. in the second. The apparent resultant momentum in each star is approximately 3,000 MeV./*c*, and is directed downwards, assuming the distribution of the neutrons to be roughly isotropic.

The primary particles responsible for these two stars leave no apparent tracks in the emulsion, and so must have charge less than three, since the smallest

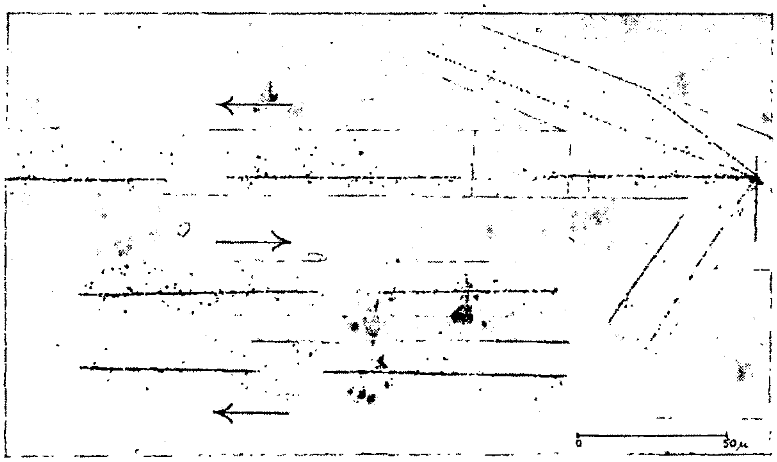

Fig. 2. Nuclear disintegration in which a heavy particle penetrating three films is emitted. The separate mosaics are sections of the tracks in three successive films. Observer: D. H. Perkins

ionization observable in Ilford $C.2$ plates is approximately six times minimum. In order to carry this momentum with a moderate mass, they must be moving with relativistic velocities. Hence the energy transfer, of the same order as the momentum transfer, is very large compared with the estimated excitation energy. The remaining energy can be accounted for either by assuming the isotropic emission of several very energetic neutrons, or perhaps by multiple meson production.

Note added in proof. Since communicating this letter, Dr. G. P. S. Occhialini has sent us details of a taper track similar to the one shown in Fig. 1. See Bonetti, A., and Dilworth, C., Bulletin de l'Université Libre de Bruxelles Note No. 7, January 1949.

Cross-Section for Nuclear Disintegration Produced by Cosmic Rays

IT has been suggested[1] that the cross-section for star production is proportional to the geometrical cross-section of the nucleus. In order to establish this by direct experiment, we have exposed some 'gelatin sandwich' plates for fifty days at a height of 3,650 m. These plates consist of four layers of Ilford $C.2$ Nuclear Research emulsion, 30 μ thick, separated by three thin layers of plain gelatin. This sandwich emulsion, coated on an acetate base, was supercoated with a 5 μ gelatin layer. A second batch of plates with emulsion layers of 25 μ was exposed for forty days. In order to determine the thickness of the gelatin layers (excluding the supercoat) relative to the normal emulsion, we have measured the ratio of the projections in the plane of the emulsion of track length to gap length for those tracks which pass right through the sandwich emulsion. The gaps in the tracks occur when the ionizing particles pass through the gelatin layers. From these measurements on 300 tracks of length greater than 200 μ we conclude that in the plates so far examined the mean gelatin thickness : mean emulsion thickness equals 9·2 per cent.

Stars formed in the emulsion proper can arise through the disintegration of any of its constituent nuclei (silver, bromine and light nuclei), while those formed in the gelatin layers must be due to the disintegration of carbon, oxygen or nitrogen. A charged particle passing through gelatin will not produce a developable track. Hence the latter group of stars are easily recognized as their centres are not visible. From the careful scanning of 94 sq. cm. of these plates we have so far observed

$$\frac{\text{No. of gelatin stars}}{\text{No. of emulsion stars}} = \frac{30}{516} = 5{\cdot}8 \pm 0{\cdot}7 \text{ per cent.}$$

The error quoted is the probable error on the number of stars obtained in the gelatin layers (excluding the supercoat).

We will now assume an effective cross-section for star production proportional to the nuclear cross-section, which we take proportional to $A^{2/3}$. Let ρ_r be the concentration in gm./c.c. of the rth component of atomic weight A_r; suffixes E and G are used to denote emulsion and gelatin respectively. If N is Avogadro's number

$$\frac{\text{Number of gelatin stars}}{\text{Number of emulsion stars}} = \frac{\sum\limits_{rG} \dfrac{N\rho_{rG}}{A_{rG}} A_{rG}{}^{2/3}}{\sum\limits_{rE} \dfrac{N\rho_{rE}}{A_{rE}} A_{rE}{}^{2/3}}.$$

From the composition of the emulsion and gelatin layers, as quoted by the manufacturers, and from the area of plates scanned, we calculate this ratio to be 4·53 per cent.

Experimental results therefore indicate that the ratio of the cross-sections for star production in light and heavy nuclei is greater than the ratio of their nuclear cross-sections. The results obtained indicate that in normal emulsion 36 ± 4½ per cent of stars are due to disintegration of light elements instead of 27 per cent as calculated from an $A^{2/3}$ law.

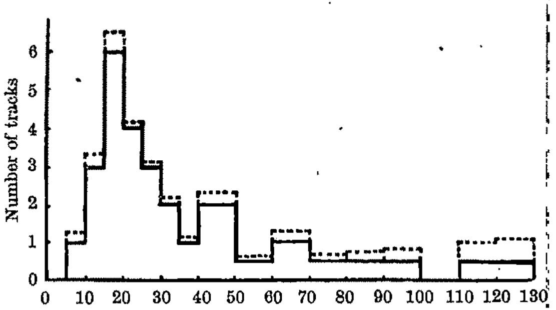
Analysis of gelatin stars. It is clear that large stars cannot be produced in the gelatin, for only light nuclei are present. The largest stars so far obtained in this laboratory have five prongs, one of which corresponds to the complete disintegration of oxygen into three α-particles, two protons and neutrons. The observed numbers of 2-, 3-, 4- and 5-pronged stars are 4, 16, 8 and 2 respectively. In so far as the statistics allow, this size distribution is seen to be similar to the one observed for the small stars (less than six prongs) in normal emulsion[2].

It is extremely difficult to distinguish between the track of an α-particle (less than 50 MeV.) and that formed by a heavier particle such as lithium or beryllium. In the gelatin stars we have observed a total of fifty-five singly charged particles and forty-three having at least two charges. Assigning a charge of exactly $2e$ to each of this latter group, we find the average charge permitted per star is $4{\cdot}7\,e$, which is about $2e$ less than the average nuclear charge. This 'loss' of charge might be accounted for in three ways : (1) by the ejection of very fast singly charged particles which do not leave visible tracks in the emulsion ; (2) by the ejection of a group of charged particles of short range, the majority of which remain in the gelatin layer ; (3) by assigning more than two charges to a number of the heavily ionizing particles.

At present we cannot estimate the effect of process (1) ; but experiments with electron-sensitive emulsions should enable us to obtain the number of very high energy particles ejected per star.

Regarding the second process, it may be noted that in normal emulsion only one third of the small stars have tracks of less than 10 μ (average range, 5 μ)[3]. If all these come from light nuclei, which seems improbable, a maximum of about one track of short range is produced per light disintegration. The stopping power of gelatin is about half that of normal emulsion, and so such tracks should have a mean range of 10 μ in gelatin. The probability of a track of length l remaining in a layer of thickness d is $d/2l$. Hence with d, the thickness of the gelatin layer, equal to 3·6 μ, the probability of a track of 10 μ remaining in the gelatin is about one-fifth. Thus four-fifths of such tracks should pass into the emulsion, and we might reasonably expect to see half of these. As yet we have not observed any. It therefore seems that the estimate of one short track per star is far too high (possibly by a factor of 3). We think it is unlikely that even an average charge of $\frac{1}{2}e$ could escape detection, due to the thickness of the gelatin layer.

It therefore seems probable that about half the heavily ionized tracks are formed by particles having a charge in excess of that carried by an α-particle.



The range distribution of the complete heavily ionized tracks is shown in the accompanying histogram, which has been corrected for loss of tracks due to (*a*) those remaining in the gelatin layers, (*b*) those which pass out of the emulsion. The corrected distribution is shown by the dotted curve.

This work is being continued, and will be reported more fully upon completion.

Structure of Molecular Films of Stearic Acid on Copper

Electron diffraction patterns obtained during an investigation of the effect of temperature on mono- and multi-molecular layers of stearic acid on copper have produced evidence for the existence of crystallites of a metal soap on the copper surface.

The layers of acid were deposited by the Langmuir–Blodgett method[1] on a metal surface which had been finely polished with rouge on 'Selvyt', degreased electrolytically and rinsed in distilled water. Three or more layers give diffraction patterns at 20° C. consisting of strong grease bands (Fig. 1), corresponding to the different orders of the 2·54 A. alternate carbon-to-carbon spacing in the hydrocarbon chain. On raising the temperature of the metal support, the bands gradually fade. At 80–85° C., while the band pattern is still visible, continuous rings corresponding to spacings of 3·76, 4·17 and 4·38 A. appear (Fig. 2). These rings increase in intensity with temperature, and at approximately 100° C. begin to arc. Further faint rings appear, until, at 115° C., there is a strong cross-grating pattern (Fig. 3). The pattern persists until at a temperature of 127–130° C. it fades suddenly, leaving a diffuse background.

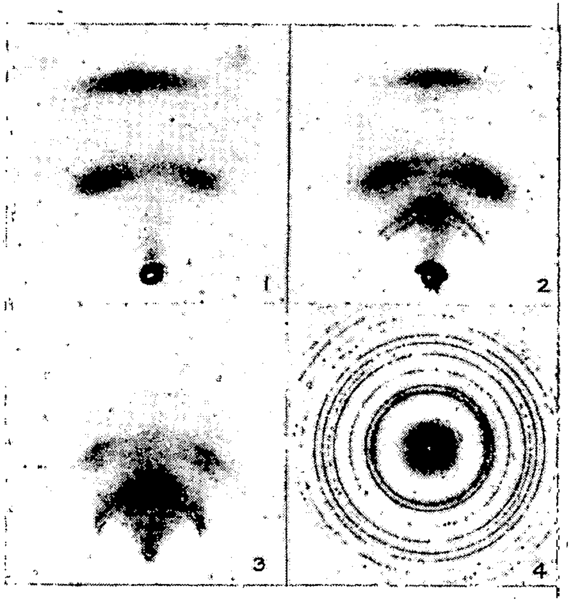

Fig. 1. Reflexion pattern of 7 layers of stearic acid on copper at 20° C.
Fig. 2. Same, after heating to 95° C.
Fig. 3. Same, after heating to 115° C.
Fig. 4. Transmission pattern of copper stearate dissolved from copper surface

The obvious conclusion, that the rings are due to the appearance of copper stearate, was confirmed by comparison of the planar spacings with those obtained from transmission patterns of a copper stearate powder prepared in the laboratory. When a specimen giving the pattern shown in Fig. 3 is boiled for several minutes in pure benzene, the subsequent solution after evaporation on a collodion support gives a strong transmission pattern (Fig. 4). The strongest two rings correspond to spacings of 3·76 and 4·17 A.

From these observations it would appear that at some temperature below 80° C. the stearic acid begins to melt (if one can speak of melting in such layers), reacts with the copper and forms copper stearate. (The bulk melting point of stearic acid is 69° C.; copper stearate softens at approximately 125° C. The effect of the metal surface on the melting point of molecular layers of such compounds is being investigated.) The stearate gradually collects into discrete crystallites, projecting from the metal surface and showing some preferred orientation. The pattern indicates that the crystals are oriented with their (001) plane parallel to the metal surface. At 130° C. the crystals melt.

Further experiments, however, indicate that, if the multi-layers on copper are allowed to age for some days, similar crystallites are obtained at temperatures well below the melting point of stearic acid. Melting of the acid apparently merely accelerates the reaction and subsequent crystallization.

Reaction between molecular layers of polar compounds with the underlying metal or metal oxide surface has been proposed by previous workers[2-4]; but no definite electron diffraction evidence of the existence of the products of such reactions has previously been reported. The conception of the crystallization of multilayers of long-chain compounds is not a new one. Coumoulos and Rideal[5] reported in 1941 that molecular layers of long-chain esters on nitrocellulose supports crystallized on ageing.

Further work on other metals is in progress.

My thanks are due to Dr. A. L. G. Rees for permission to use the electron diffraction camera of the Chemical Physics Section, Division of Industrial Chemistry, and for his constant advice and criticism. The work forms part of the general programme of research of the Tribophysics Division of the Council for Scientific and Industrial Research.

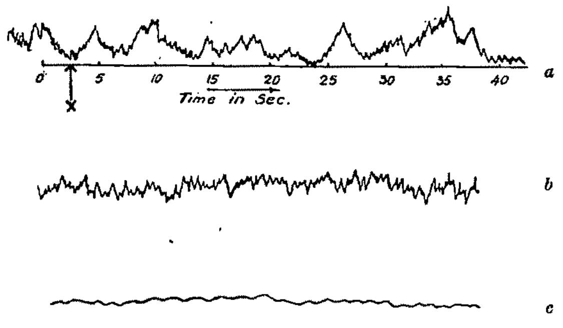
A Peculiar Type of Rapid Fading in Radio Reception

WHILE studying the field-strength variations at Waltair of transmissions from certain broadcasting stations of the All-India Radio, a peculiar type of rapid fading, which does not appear to have been reported so far, was observed during the summer months on the 41- and 60-metre bands. The phenomenon may briefly be described as the apparent existence on the carrier, at the receiving end, of a permanent modulation of 2–3 cycles per second. When the programme is on, there is superposed on it a variation in intensity at frequencies ranging between 2 to 3 cycles per second. This gives the impression of a quivering or fluttering of the transmission. This phenomenon is therefore referred to here as the 'flutter phenomenon'. The effect produced in the loud-speaker by the 'flutter' is somewhat similar to the beating of two notes of nearly the same frequency. When the quasi-frequency of the 'flutter' becomes large, it produces a most annoying effect, and listening to a programme becomes almost impossible. The effect is further accentuated by occasional large amplitude of the 'flutter'.

A study of the phenomenon with respect to the evening and night transmissions of All-India Radio (Madras) showed the following features: (1) It occurs only during the summer months. In 1948 it started about the second week of February and continued to the end of June almost every day. (2) The 'flutter' appears at about the period of sunset. The quasi-flutter frequency is low (about 20–30 c./min.) before sunset, but increases (to 120–140 c./min.) up to a point in the night and thereafter remains practically constant.

Although this effect was observed on the Madras transmissions, it was noticed on the 41-, 49- and 60-metre bands transmissions from other stations of All-India Radio as well, and occasionally on the 19-metre band. It is completely absent on the medium wave-band.



A trace of galvanometer records incorporated in a field-strength measuring equipment is given in the accompanying diagram: curve (*a*) refers to All-India Radio (Madras) on 41 metres; curve (*b*) to the Colombo transmissions on 61 metres; and curve (*c*) refers to the transmission of All-India Radio (Trichinopoly) on 396 metres. The curves were taken at 2000 and 2045 hr. I.S.T., on June 16, 1948.

It is seen from the curves that there is a slow fading with periods ranging from 3 to 4 sec. giving rise to what clearly appears as the usual slow type of fading, the signal strength fluctuating between 2,000 μV./m. to 200 μV./m. Superposed on this are the small, fine discontinuities which make the trace appear rugged. It is this rugged structure which is noticed as the 'flutter'. At the point marked *X*, the number of these discontinuities is 12 in a period of 5 sec., that is, it occurs at intervals of approximately 0·5 sec. or at a frequency of about 140 cycles per minute.

The rugged structure of the curves reminds one of the irregular scatter groups obtained by Eckersley[1] and the occurrence of flickering reflexions from the *F*-region reported by Beckmann, Menzel and Vibig[2]. A peculiar type of rapid fading (about 37 cycles per minute) was observed by Appleton and Beynon[3] during the period of sunset due to the reception of the Pedersen ray. The phenomenon described here is different from the above in that the rapid fading noticed by the above authors was only during a period of 14 min. passing through sunset; but the one described here commences about the period of sunset and persists over long periods. Therefore the ionosphere must in some way be responsible for the 'flutter' phenomenon, although the exact method of production of this effect is not known. If the rapid movement of the ionic clouds across the *F*-layer is a regular process as observed by Wells, Watts and George[4], the effect reported above may be produced by these clouds. The speed and the number of clouds that pass a given point in space may to a large extent determine the frequency of the rapid fading produced.

Tilting-Plate Compensators

THE various communications describing ingenious modifications of the tilting-plate compensator which have appeared in *Nature* in recent months suggest that a rather different form, which I improvised from a pair of selenite plates, might be of some interest, particularly as the special materials mentioned by previous contributors are not always immediately available.

The essential optical element of this compensator consists of a pair of optically identical birefringent plates, mounted one upon the other with their vibration planes mutually perpendicular. In consequence of the latter feature, their respective retarding powers are in opposition, but are equal in magnitude only for the special case of normal transmission, the total retardation then amounting to zero. For all other directions of transmission their respective retardations differ, resulting in a total retardation which increases as the combined plates are tilted away from the normal. Viewed normally between crossed Nicols in convergent light, the plates yield a conoscopic interference figure resembling that of a single plate of uniaxial material cut perpendicular to the optic axis. It is thus possible to construct a tilting optical element giving a zero retardation for normal transmission.

The advantage of this form of compensator is that the plates can be made from almost any birefringent material whatsoever, since the orientation of the optic axis or axes does not affect the mutual neutralization for normal transmission. The present optical element consists of two plates of selenite of 2·5 mm. thickness, giving a compensating range of about four wave-lengths; but mica would probably be preferable because it would permit of thinner plates. In the case of the most common form of mica, the normal bisects the acute angle of the optic axes, so that a pair of opposed mica plates have to be tilted through only a comparatively small angle to bring an optic axis of one of them into coincidence with the direction of transmission. When one of the mica plates is in this particular position, its retarding effect is zero, while that of the other will be rather greater than for normal transmission. Consequently, if each mica plate is of such thickness as to introduce a retardation of, say, four wave-lengths, a total retardation exceeding this value will be obtained when the plates are combined in opposition and tilted into the above position.

The calibration may be computed along the lines mentioned by F. Record[1], with the difference that there are two plates to be computed separately, each pair of values corresponding to a given angle of inclination being afterwards added to provide the calibration curve.

Mounting the two plates separately in such a manner that they can be tilted independently of one another suggests further possibilities which might be worth investigating.

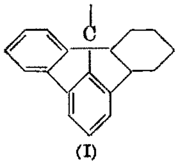
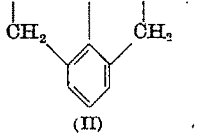
1 : 9-*cyclo*Hexylenefluorene

Hurd and Mold[1] have recently described the dehydration of 2-fluorenyl*cyclo*hexanol to a saturated hydrocarbon to which they attribute the structure (I) of 1 : 9-*cyclo*hexylenefluorene. If this structure were correct, the result would be of considerable importance, for it would represent the first successful attempt to prepare a compound having the highly strained ring-system (II) which von Braun had completely failed to obtain[2].



(I)



(II)

It is very unlikely, however, that the hydrocarbon of Hurd and Mold has the structure (I). The dehydration of their carbinol is probably analogous to that of 2-benzyl*cyclo*hexanol, which gives a bridged ring hydrocarbon[3]. Experiments to test this hypothesis are being initiated.

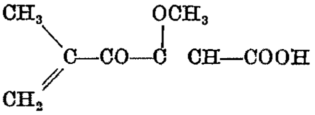
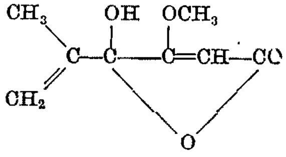
Tautomerism of Penicillic Acid

THE existence of tautomeric forms of penicillic acid was first postulated by Birkinshaw, Oxford and Raistrick[1]. Recent workers have tended to the view that the hypothesis of tautomerism was not needed to explain the chemical properties of penicillic acid[2].



(I)

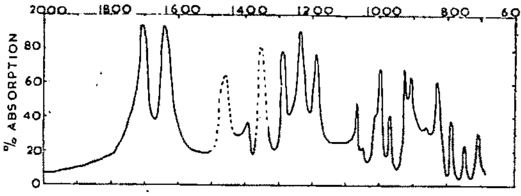


(II)

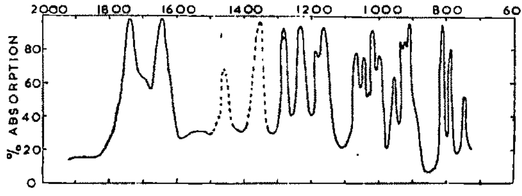
However, the infra-red spectra of penicillic acid furnish conclusive evidence for the existence, in the solid phase at least, of two tautomeric forms. The infra-red spectra of the two forms are shown in Figs. (i) and (ii). Spectrum (i), with carbonyl absorption band at 1,714 cm.$^{-1}$, is that of the keto acid (I); and spectrum (ii), with carbonyl absorption band at 1,738 cm.$^{-1}$, is that of the lactone form (II). Key bands for each form are:

Keto acid	1,714	1,393	967	831			cm.$^{-1}$
Lactone	1,738	1,165	1,032w	956	935	808	cm.$^{-1}$

The infra-red spectrum of the sodium salt of penicillic acid has been obtained. This contained no lactone carbonyl absorption band, but a powerful new band at 1,550 cm.$^{-1}$ was observed, indicating the formation of a carboxyl ion. It was concluded that the sodium salt was the salt of the keto acid and not an enolic salt.



(i)



(ii)

The two forms of penicillic acid can be readily interconverted. The lactone form was produced by melting the keto acid and allowing it to crystallize. It was also formed by prolonged grinding of the keto acid in 'Nujol'. When the lactone form was dissolved in ether and recrystallized, the keto acid was again produced. By suitable physical treatment, all types of mixture from 100 per cent form I to 100 per cent form II can be obtained.

A number of analogues of penicillic acid have been examined; but no further examples of tautomerism have been observed.

In view of the widespread use of the method of grinding in 'Nujol' for analytical work in the infra-red region, attention may be directed to the fact that in the case of materials existing in tautomeric forms with small energy differences, radical changes in the infra-red absorption spectrum can be produced by grinding. Prolonged grinding has been recommended[3] as a means of securing random orientation of the crystals in the absorption cells; but the possibility of changes occurring due to tautomeric interconversion should always be borne in mind.

A full account of this work will be published elsewhere. Thanks are due to Dr. R. A. Raphael for his kindness in supplying specimens of synthetic[4] and natural penicillic acid and their analogues, to Mr. L. Beecher for assistance with the experimental work, which was carried out for the Chemical Inspectorate, Ministry of Supply, at the Royal Arsenal, Woolwich, and to the Chief Scientist, Ministry of Supply, for permission to publish.

Oxidation of α-Diketones and α-Keto-Acids by Hydrogen Peroxide

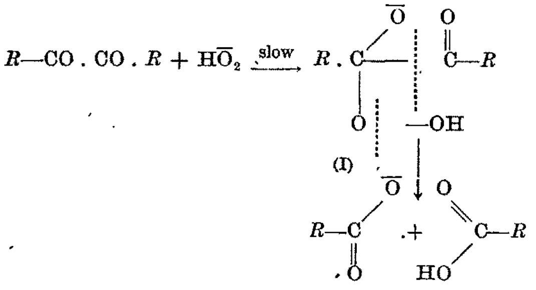
THE oxidation of α-diketones and α-keto-carboxylic acids by hydrogen peroxide involves the breaking of the carbon–carbon bond between the carbonyl carbon and the carbonyl or carboxyl groups[1].

R—CO . CO . R + $H_2O_2 \rightarrow 2R$—CO . OH ;

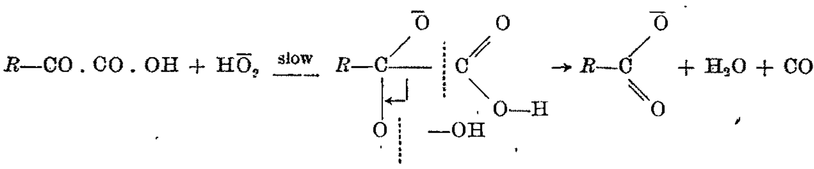
R—CO . CO . OH + $H_2O_2 \rightarrow R$. CO . OH + $H_2O + CO_2$.

This note discusses the mechanism of these reactions in the light of new experimental evidence, and in terms of suggestions I and my co-workers have previously made[2].

The kinetics of these oxidations have been studied in aqueous solutions, and a very marked base catalysis is observed. Such base catalysis is frequently found in the reactions of hydrogen peroxide, and it is considered to indicate a rate-determining attack by the hydroperoxide ion, formed by the ionization of the hydrogen peroxide. The reaction mechanism suggested for the reactions now considered involves the addition of this nucleophilic ion to the carbonyl carbon atom. The conclusion that the addition is rate-determining is in accord with what is known concerning additions of other nucleophilic anions, for example, the cyanide ion, to carbonyl groups.



(I)



(II)

The kinetics give little information as to the life of the intermediates, I and II, which probably have at most a transient existence.

The base catalysis is observed in the oxidation by hydrogen peroxide of diacetyl and sodium pyruvate, and also of benzil and sodium benzoylformate. Neither of these latter compounds can undergo enolization, and therefore this base catalysis cannot be explained by any mechanism which involves the enolization of the compound.

Mechanisms involving free radicals derived from hydrogen peroxide are also excluded under our experimental conditions. It is found that hydrogen peroxide in the presence of slightly acid ferrous or ferric salts, a recognized source of free hydroxyl radicals[3], does not readily decarboxylate benzoylformic acid. Furthermore, pyruvic acid can actually be prepared by the oxidation of lactic acid with ferrous sulphate and hydrogen peroxide[4].

A detailed account of this work will be published later.

Demethylation of N : N-Dimethyl-*p*-Aminoazobenzene (Butter Yellow) with Hydrogen Peroxide

THE reaction which butter yellow undergoes with the Milas reagents[1] (hydrogen peroxide in *tert.* butyl alcohol with osmium tetroxide as catalyst) is being studied in detail to determine the extent to which it parallels the reaction occurring with this substance *in vivo*, since the *in vitro* reaction is accompanied by a chemiluminescence[2]. Miller and Miller[3,4] have recently given evidence that hydroxylation of butter yellow or its demethylated derivatives occurs to some extent in the rat, and, as it was expected that the Milas reagents would effect hydroxylation of the substance, they seemed suitable for the comparison. Separation of the reaction products, however, also showed that much of the action had taken place at the tertiary nitrogen atom. The following results have been obtained so far.

0·75 gm. of butter yellow, which had been previously freed from traces of the monomethyl compound and the free base by chromatography using an alumina column and petroleum ether (60–80° C.) as solvent and eluent, was dissolved in 270 ml. of an 8·1 per cent solution of hydrogen peroxide in *tert.* butyl alcohol, and 7 ml. of a 0·5 per cent solution of osmium tetroxide in *tert.* butyl alcohol was added to this. The mixture was maintained at 37° C. for 12 hours, since this was the temperature at which the chemiluminescence observations had been made. The alcohol solution was then diluted to 2 litres with water and extracted with 4 litres of benzene. The benzene extract was concentrated and passed on to an alumina column. After elution of the different zones and repeated chromatography of these, a large number of different eluates was obtained. The materials producing four of these zones were (*a*) 0·11 gm. unchanged butter yellow, (*b*) 0·13 gm. N-methyl-*p*-aminoazobenzene, (*c*) 0·013 gm. *p*-aminoazobenzene, (*d*) 0·013 gm. *p*-nitroazobenzene. The materials were identified by comparison of solubilities and colours in dilute hydrochloric acid, chromatographic behaviour and finally melting-points, with those of samples of known compounds. For the small fractions of *p*-aminoazobenzene and *p*-nitroazobenzene, absorption spectra provided confirmatory evidence. Another small fraction has been obtained which has acid and basic properties and would therefore seem to be a hydroxyl derivative of butter yellow or its demethylated products.

The remainder of the reaction products are still being investigated; but the reactions which take place at the dimethylamino-group seemed worthy of separate note. The removal of alkyl groups from aromatic tertiary amines is not uncommon in *in vivo* reactions; but little is known of the reaction mechanism and the process is simply referred to as 'dealkylation'. Studies with amine oxidase[5,6] show that a number of amines undergo oxidation at the carbon–nitrogen linkage in the presence of this enzyme, and the experiments of Hess *et al.*[7] on cyclic $>N.CH_3$ compounds containing a ketone or aldehyde grouping (derivatives of pyrrolidine and piperidine) afford examples of intramolecular oxidative demethylation. The reaction described above provides an example of oxidative demethylation of an aromatic tertiary amine, effected by hydrogen peroxide.

Methylation in the Study of Polynucleotides

ALTHOUGH detailed knowledge of the components of pentose nucleic acids is still incomplete, considerable effort over a long period has been directed towards the problem of the mode of union of the constituent nucleosides. It was early recognized that these units are linked through phosphoric acid residues, and the precise manner in which this takes place has been studied more recently by electrometric titration[1].

As regards the groups in the nucleoside radicals which are concerned in the structure of the polynucleotide, direct evidence that carbohydrate hydroxyl groups are involved is scanty. It is now known that all four nucleotides, isolated after mild alkaline hydrolysis of the pentose polynucleotide of yeast, possess phosphoric ester groupings at position 3 of the sugar residue, and the question has been discussed whether di-ester linkages exist between positions 2 and 3 or 3 and 5 of the different nucleosides making up the polynucleotide[2]. Since, however, yields of the nucleotides are always far below expectation, it cannot be assumed that all the nucleosides are esterified in this way, and an open mind must be kept regarding the precise parts played by the carbohydrate radicals and the phosphoric acid residues in the internucleosidic linkages.

It is clear, therefore, that a technique is required whereby uncombined carbohydrate radicals may be counted and identified, in order that a complete picture of the mode of linkage of the carbohydrate radicals may be obtained. Methylation of yeast nucleic acid has been investigated with this end in view, as mentioned by the late Prof. J. Masson Gulland[3]. Since his death, this work has been carried forward and is now briefly reported. Levene records that the use of Purdie's reagent[4] brought about decomposition of nucleotides and nucleosides at a greater rate than methylation. In the absence of experimental details concerning this breakdown, it was decided to attempt again to make use of this reagent for the methylation of the pentose polynucleotide of yeast.

Repeated treatment of a suspension in methanol of yeast nucleic acid purified by the method of Sevag, Lackman and Smolens[5] with methyl iodide and silver oxide resulted in the formation of approximately eight, and no more, methoxyl groups per statistical tetranucleotide, four of which were assumed to be located on the phosphoric acid residues, since they could be hydrolysed readily by boiling aqueous sodium hydroxide. It was found that if methylation was carried out at the boiling point, the product was pale brown in colour, was deficient in nitrogen and contained no methylamino groups. If, however, experiments were conducted with vigorous shaking at 25° C., methylation proceeded satisfactorily, giving a pale straw-coloured hygroscopic powder, soluble in water and methanol, but insoluble in methyl iodide, acetone and ether, and possessing eight methoxyl groups as before and also approximately six methylamino groups per statistical tetranucleotide.

The degree of success attained in these experiments must be judged, for the present purpose, according to the extent to which the state of combination of carbohydrate hydroxyl groups involved in the internucleosidic links has been altered during methylation. If the assumption, for which there is no real justification at present, be made that carbohydrate radicals are involved in all the internucleosidic linkages, the molecular weight of the methylated product is probably the most reliable criterion. Accordingly, molecular weights were determined by the method of Fletcher, Gulland and Jordan[6] before and after methylation, and it was found that the nucleic acid had suffered no appreciable degradation. The values of the molecular weights, estimated from measurements of the diffusion coefficients by making the same assumptions as those made by Fletcher, Gulland and Jordan[6], range from 10,000 to 12,000 for the nucleic acid before methylation, and from 13,000 to 15,000 after treatment. It is considered, therefore, that this method of investigation promises well to attain in some measure the object in view. Before it is possible to state exactly the nature of nucleic acid methylated in this way and to isolate and identify fragments of the molecule, a study must be made of the effects of the above reagents on simple constituents of the polynucleotide molecule. Work is in progress to this end and will be reported elsewhere.

Resonance and Molecular Structure

There is now sufficient evidence available from accurate measurements of molecular dimensions to state with a fair degree of certainty that the ideal hybrid bonds of quantum mechanics are only found where the symmetry of the bonded system is identical with that of the hybridized atomic orbitals. It would seem that the presence of any asymmetry caused the angles between the bonds to deviate from the ideal values characteristic of the symmetrical system. Since the deviations are generally quite small (though now well outside the possible limits of experimental error in favourable cases) it seems probable that these asymmetric systems are resonance hybrids, in which there are small contributions from structures usually ignored. Thus, it is possible to account for the observed facts in the methyl halides as follows.

We assume that the ψ-function of the molecule CH_3X can be written as a linear combination of three functions characteristic of the structures I to III below:

$$\underset{\text{(I)}}{CH_3{-}X} \qquad \underset{\text{(II)}}{\overset{+}{C}H_3\ \overset{-}{X}} \qquad \underset{\text{(III)}}{\overset{-}{H}\ CH_2{=}\overset{+}{X}}$$

there being three equivalent structures III. In symbols,

$$\psi = a_1\psi_{\text{I}} + a_2\psi_{\text{II}} + a_3\psi_{\text{III}}, \qquad (1)$$

where $a_1^2 + a_2^2 + a_3^2 = 1$.

The required data are summarized below

X =	F	Cl	Br	I	
[1] $\theta_{\angle HCH}$	111° 48′	111° 52′	112° 6′	112° 12′	
[2] k_{CH}	4·71	4·90	4·95	5·00	× 10⁵ dynes/cm.

The small variations are thought to be real. The decrease in the C—H stretching constant k_{CH} encountered in passing from iodide to fluoride suggests an increase in a_3 in (1) in the same direction; this would be expected from what is known of the relative powers of conjugation of the halogen atoms. Now if we assume that in the structure (1), in which $a_2 = 0$, the two single bonds from III are effectively distributed over a cone with vertical angle 120°, cylindrically symmetrical about the axis C_3, then the angle HCH in the hybrid will be less than the normal tetrahedral value, the increment increasing with a_3. If, in addition, we assume that the positive methyl ion in II is itself a resonance hybrid, with a small contribution from the trigonal sp_2 structure (which seems reasonable, since here there are only three bonds actively employed), then the angle HCH in II will be greater than normal. Clearly, the structure (I) in which $a_3 = 0$ will then also have HCH angles greater than normal. If now both a_2 and a_3 are non-zero, and a_3 increases with respect to a_2 in passing from iodide to fluoride, then all the facts can be explained.

As a second example, consider the anomalous fluorinated ethylenes. In both vinylidene fluoride and tetrafluoroethylene, the C=C stretching frequency is abnormally high[3]. Resonance with structures of the type $\overset{-}{C}H_2{-}CF{=}\overset{+}{F}$ will account for increased C—F stretching frequencies, but would lead simultaneously to a decrease in $\nu_{C=C}$. It has been found that the non-planar $=CH_2$ bending frequency can be used as a measure of the extent to which the above resonance occurs in substituted ethylenes[4]; the large effect observed in vinyl and vinylidene fluorides[3,4], if all attributable to this resonance, would certainly be associated with a decrease in $\nu_{C=C}$. The observed increase can only come from resonance with structures such as $\overset{+}{H}\ CH{\equiv}CF\ \overset{-}{F}$, which become of importance with the fluorides because of the high electro-negativity of fluorine. It is possible that the large negative increments in δ_{CH_2} are also partly due to structures of the above type, since it is known that δ_{CH} is smaller for C—H bonds adjacent to triple bonds. Further, such structures would diminish the angle FCF; there is some evidence[3] that in $CH_2{=}CF_2$ this angle is as small as 112°.

There are other cases where the same principle may be applied. Thus, in formaldehyde[1], resonance with the single-bond structure $\overset{-}{O}{-}\overset{+}{C}H_2$ accounts for the increase (of 3° 26′) in the angle HCH over the normal trigonal value of 120°, the argument being analogous to that used to explain the assumed decrease of the tetrahedral HCH angle in the resonance hybrid $\{CH_3{-}X,\ \overset{-}{H}\ CH_2{=}\overset{+}{X}\}$. In phosgene, the chlorine atoms favour resonance of the type $\{O{=}CCl_2,\ \overset{-}{O}{-}CCl{=}\overset{+}{Cl}\}$, which would leave the trigonal angle unaffected; actually a decrease is observed, ($\theta_{\angle ClCCl} =$ 117°)[5], which may be attributed to the presence of small contributions from structures $O{=}C{=}\overset{+}{Cl}\ \overset{-}{Cl}$.

In conclusion, it may be mentioned that there is some evidence to show that the directions of bonds may be inclined at an angle to the line joining the nuclei of the bonded atoms. This idea was developed in connexion with highly strained cyclic systems[6]; but it is possible that it is applicable to the cases discussed in this note.

Radioactive Emanating Power and Ultrasonic Treatment

It seems in certain cases reasonable to suggest an influence of ultrasonic treatment on radioactive emanating power[1]. Ultrasound may bring about changes in a solid substance which involve changes of the emanating power, either by affecting the specific surface or the diffusion coefficient of the emanation in the solid phase. A change of the former property should be permanent or show remanence, whereas a change of the latter should be restored after ceasing ultrasonic treatment. It should thus be possible to conclude which of the two changes has occurred.

We have started a study of the effect of ultrasound on the emanating power of gels of metal oxide hydrates. A dilute solution of aluminium chloride was precipitated in the cold with ammonia in the presence of radium–thorium. The carefully washed precipitate was centrifuged, and dried for seven days above concentrated sulphuric acid. It was then placed in the open air.

Measurements were made by the streaming method for radium–thorium often described[2], which affords an almost instant reading of the relative changes in the emanating power. In order to measure the activity of the emanation, we used a modification of the ionization electrometer according to Zimens[3]. A Crystalab ultrasonorator, model SL 520, Fisher Scientific Co., with a maximum effect of 500 watts was used as ultrasonic source. The frequency was 1,500 kc. The sample was exposed to the ultrasonic waves through the thin wall of a glass tube, which was placed in the oil fountain.

The experiments so far made have shown an immediate increase in emanating power caused by the ultrasonic waves. Thus in a typical experiment we got an increase amounting to 26 per cent. The high value remained constant for an hour, after which a slow decrease might perhaps be observed. The increase depends on the sound effect. In another experiment we got an increase of 24 per cent, at a generator output of 100 watts, and this value increased gradually to 33 per cent, as the generator output was increased to 500 watts. It must be remembered that the efficiency in this simple but typical experimental arrangement can scarcely be ascertained. It is, however, quite low.

These preliminary experiments seem to indicate that treatment with ultrasound brings about a disintegration of the agglomerates of the aluminium oxide hydrogel. From experiments of an entirely different character, Sata and Naruse have come to a similar conclusion[4]. In our case, however, another interpretation is possible, namely, that the ultrasound may have an influence on the amount of water absorbed by the gel, thus causing a change in the emanating power[5].

Some Pharmacological Properties of Sodium Ethyl, 3 : 3 Dimethylallylbarbiturate

Preliminary observations have shown that when sodium ethyl, 3 : 3 dimethylallylbarbiturate was administered to dogs and cats, it produced a marked stimulation of gastric and salivary secretion. The stimulation appeared to be of central rather than peripheral origin[1-3].

Further studies with this compound, No. 16-*A* (Eli Lilly and Co.), have disclosed that it possesses other powerful pharmacological properties not usually ascribed to barbituric acid derivatives. It appears that the actions of this substance are the exact opposite of the ordinary hypnotic barbiturates. The effects studied so far show that it causes a distinct rise in blood pressure even when given intravenously; it causes an immediate marked stimulation of depth and frequency of respiration, and the body temperature is sharply raised. In unanæsthetized animals, overdosage is associated with restlessness, muscular contractions and violent convulsions. The animal's temperament appears to change, so that it appears frightened and becomes bold and vicious. Sympathetic over-activity may be noted. Death occurs following convulsive episodes and may be due to spasm of respiratory muscles, since anæsthetic doses of ordinary barbiturates may increase the tolerance to five to six times the M.L.D. for unanæsthetized animals.

The M.L.D. for cats and rabbits is approximately six to seven mgm./kgm. when administered intraperitoneally or intravenously. Symptoms occur when doses of 3–4 mgm./kgm. are reached. Cats anæsthetized with pentobarbital will tolerate total doses of 50 mgm./kgm. given over four hours. An intravenous dose of 5 mgm./kgm. in such a preparation caused a rise of 36 mm. mercury in blood pressure, which rapidly returned to normal.

In unanæsthetized animals, respiration is markedly stimulated, and vigorous panting occurs for approximately three hours; the rate may reach 180 per min. The rectal temperature rises to 105–107° F. and may reach 112° F. at death.

The isolated gut suspended in Ringer's solution is first stimulated and then narcotized when total concentrations of 0·01 per cent of 16-*A* are reached. During the latter stage, the gut fails to respond to added acetylcholine or histamine, but the response rapidly returns after washing out the barbiturate solution.

The antagonistic action of this compound to ordinary barbiturates suggests that it may be used to overcome some of their undesirable effects, such as depression of respiration and blood pressure, and might be of value as an antidote to barbiturate poisoning. Preliminary experiments indicate that an anæsthetic mixture of 16-*A* and pentobarbital may be rapidly given intravenously to rabbits without causing respiratory paralysis.

Colour Vision

HAVING read the article on colour vision in *Nature* of October 23, 1948, and having heard the spontaneous comments of a number of people who have read that article, I am under the impression that readers who were not present at the Brighton meeting have got a somewhat incorrect impression as to the true state of affairs so far as the rival theories are concerned.

In the first place, there appears to have been a misunderstanding as to the interpretation which should be placed on papers recently published by Prof. R. Granit in the *Journal of Neurophysiology*. It is clear that some readers of his paper have gained the impression that Prof. Granit has abandoned the polychromatic theory on the grounds that many, if not all, types of modulator, which he has found in the eyes of animals, might be built up from receptors of three types only: red, green and blue. Let us accept this suggestion in order to examine its implications more closely. By some physiological process of summation or inhibition, the details of which are at present unknown, a trichromatic arrangement of receptors co-operates to produce a number of different functional units, which are distributed fairly uniformly throughout the spectrum, and have somewhat narrower response curves than the receptors from which they are produced. Now the important point, so far as colour vision is concerned, is that such functional units exist, because it is with these that the polychromatic theory is primarily concerned.

With regard to colour-matching data, three incorrect ideas appear to be held by some supporters of the three-colour theory. The first is that a colour match is stable under a wide range of light and colour adaptation. This is contrary to recent experimental findings, because it is now known beyond all possibility of dispute that either a considerable increase of light intensity, or a marked decrease of light intensity, or the adaptation of the eye to a bright light, markedly alters certain colour matches. So also do variations in the size of the test field. There is a further point in this connexion. It used to be supposed years ago not only that one subject with normal colour vision would accept the colour matches made by another, but also that colour-blind persons would do so as well. It is now known, however, that none of these ideas is correct. Not only is it unusual for one subject to accept the colour matches of another, but also it is sometimes found that colour matches made on one day are unacceptable to the same subject on the following day. Moreover, it is true that certain colour-blind persons will accept the matches made by normal-sighted subjects; but this is not true of all types of colour blindness. The protonomalous trichromatic observer may be specifically mentioned in this connexion.

The fact that additive mixtures of red, green and blue radiations produce colours which are too desaturated for an exact match with the spectral colours is claimed to be explicable on the ground that no physical stimulus, particularly no green stimulus, is capable of stimulating only one receptor; that is, that the sensitivity curves are broad ones, overlapping to some considerable extent in the spectrum. Two points should be noted in this connexion: first, that no confirmatory evidence has so far been produced for the statement that the sensitivity curves are broad ones; and secondly, that such an assumption is found to lead to erroneous conclusions so far as certain types of colour blindness are concerned. Thus the failure of additive mixtures to match spectral colours has still to be satisfactorily accounted for on the three-colour theory.

The article in *Nature* of October 23 mentions the point that even if there were a yellow receptor, the sensation of yellowness could not uniquely be associated with its stimulation, on the ground that yellowness can also be produced by a mixture of red and green radiations, and therefore by the combined activity of the red and green receptors. This may indeed be the case; but even if true, it does not throw doubt on the existence of independent yellow receptors. Two interesting points come up for consideration in this connexion. (1) On the basis of the three-colour theory, it would be expected that adapting the eye to yellow rays would produce identical results to those produced by adapting the eye under the same conditions to a red – green mixture which matched the yellow in hue, brightness and saturation; but as previously reported, experiment shows that such is not the case. (2) Certain trichromats with abnormal colour perception describe the yellow parts of the spectrum as 'red – green', that is, there is to them no specific yellow hue which to subjects with normal colour perception is so clearly different either from red or from green. This suggests the possibility that the yellow receptors may have some more specific function to perform than existing evidence indicates. With regard to the evidence for an independent yellow receptor, it is pointed out correctly that this cannot be based on the observation that a yellow pigmented surface is replaced by white when field size is altered. It is based principally on the following evidence: (1) experiments on monochromatic yellow light produced by a monochromator or by a screened sodium electric lamp; (2) the notches which occur in the luminosity curve for foveal photopic vision when light intensity is reduced, or field-size made small; (3) the adaptation experiments referred to above; (4) the disturbance of matches between pure yellow and a red – green mixture.

I would like to terminate these comments by briefly referring to some very recent work performed by Dr. L. C. Thomson. During an examination of the shape of the luminosity curve, when test fields of small size were being investigated, he found instead of a smooth curve, such as is obtained with fields of large size, that one was obtained which showed a series of small humps and depressions, there being a particularly clearly marked hump at a wave-length of $0{\cdot}42\,\mu$. Now it is especially interesting to note two other facts. First, Granit has recently discovered a modulator which has a crest very close to this wave-length. Secondly, I obtained evidence for a receptor with a crest at, or close to, this wave-length, which possessed a specific fixation point in the fovea, and also a characteristic subjective colour when the foveal centre was explored using the microstimulator apparatus.

The situation so far as the polychromatic theory is concerned may be summarized by saying that evidence is accumulating in its favour, and that the evidence in question is at variance with the three-colour theory. So far as can be judged at present, human foveal vision is approximately trichromatic, but it is also served by additional receptors which disclose their presence under appropriate experimental conditions. To-day it seems less a matter of discussion whether the three- or the poly-chromatic theory is correct, so much as to consider the spectral situation, the spectral distribution, and the retinal distribution of the additional receptors which are postulated by the polychromatic theory.

Factors Influencing the Renal Threshold

It appears that threshold substances fall into two groups as regards their mode of tubular resorption. Glucose, xylose, phosphate, sulphate, amino acids and ascorbic acid on one hand have a definite Tm[1,2] value (maximal tubular resorption, mgm./min.) which is a measure of the active tubular cell-mass; the resorption of chloride and bicarbonate ions[3,4], on the other hand, is proportional to the quantity of glomerular filtrate.

The purpose of this note is to discuss the factors on which the threshold values of various substances depend, and to examine whether or not the difference in the resorption mechanism referred to above is reflected in the behaviour of the threshold.

For either group the value of the threshold Tx, mgm. per cent, of a substance x is such that

$$F_0 Tx/100 = Rx_0, \tag{1}$$

where Rx is the amount resorbed in the tubules (mgm./min.), F the rate of glomerular filtration (c.c./min.) and zero subscripts refer to values corresponding to the plasma concentration Tx. Evidently, for substances of the second group, where

$$100.Rx/F = \text{const.}, \tag{2}$$

$$Tx = 100.Rx/F \tag{3}$$

for any pair of values Rx and F[3,5]. This threshold is independent of the concentration of x in the plasma (Px) and of the actual values of Rx and F. It is a characteristic of the tubular function.

For substances of the first group

$$Rx = Tmx = \text{const.}, \tag{4}$$

for $Px \geqslant Tx$, and the formula of Földi *et al.*[6] can be used for the calculation of the threshold:

$$Tx = Px - \frac{P}{U}(Ux), \tag{5}$$

where P/U is the inulin concentration ratio and Ux the concentration of x in urine (mgm. per cent).

From (1), and putting $Rx_0 = Tmx$, we obtain

$$Tx = 100.Tmx/F_0. \tag{6}$$

It will be seen that, in this case, Tx is not a constant, but a function of Tmx and F_0. We have pointed out elsewhere[7] that Földi's formula can only be used if F is constant and independent of Px. It actually is so (as seen, for example, from Shannon and Fisher's data[1] for glucose), so that it is possible to write F instead of F_0 in (6). Thus, for substances having a threshold Tm,

$$Tx = 100.Tmx/F. \tag{7}$$

For every pair of values (Tmx, F), therefore, there is a threshold value $Tx_{(Tmx,\,F)}$.

Földi[8], in a recent communication, has expressed the threshold as

$$Tx = Px.Rx/Fx, \tag{8}$$

where Fx is the rate of glomerular filtration of x mgm./min., Rx is the rate of tubular re-absorption of x mgm./min., both being the values corresponding to the plasma level Px; and he has come to the conclusion that Tx is a function of the variables appearing on the right-hand side of (8). It would seem from the above discussion, however, that Tx is either itself a characteristic constant of the kidney, or a function of Tmx and F, as the case may be; but it is certainly independent of Px, the actual plasma concentration of x. Tx can, it is true, be calculated from Földi's formula, which involves Px, but the threshold is not a function of Px. We would clarify our point by a physical example: Boyle's law gives the equation of state for one mole of an ideal gas at constant temperature as

$$pV = \text{const.}, \tag{9}$$

where p is pressure and V is volume, and the constant is proportional to the absolute temperature. It is possible to calculate the constant from (9), but it cannot be said to be a function of the variables appearing in that equation. (8) is a precisely analogous equation between the variables Px, Rx and Fx, and the value of Tx is independent of the actual values of the variables, because it is constant for given values of Tmx and F.

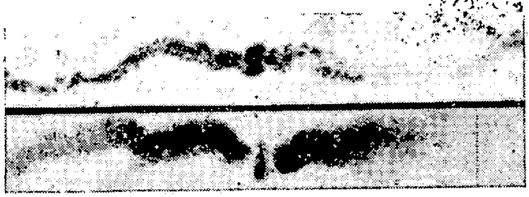
Nodes in the Central Nervous System

It is commonly stated that the nodes originally described by Ranvier[1], which are so characteristic a feature of peripheral nerve fibres, do not occur within the central nervous system. However, Ramón y Cajal, in his descriptions of those penetrating researches which have distinguished him as one of the foremost histologists of all time, refers repeatedly to *étranglements* or nodes on nerve fibres within the brain and spinal cord, and these are beautifully illustrated in some of his publications[2,3]. In spite of these observations, the absence of nodes in the central nervous system has often been assumed by some contemporary neurohistologists[4,5] and in many standard text-books of histology and neurology.

Recently, while examining several brains taken from rabbits injected intravenously with methylene blue, we have been able to confirm Ramón y Cajal's observations[6]. Deeply stained nodes, often associated with slight constrictions of the axis cylinder, have been found to be situated at intervals along tracts in many parts of the brain. Their morphological details are similar to those of nodes in peripheral fibres, including in some cases well-defined bracelets and cementing disks (see photograph). They are particularly conspicuous in fibres undergoing early degeneration, in which the axoplasm is metachromatically stained purple while the nodes remain a deep blue-



Nodes of small and large fibres in the optic tract, stained by intravenous methylene blue. (× 1,240)

green colour. In the central nervous system, as in peripheral nerve fibres, bifurcation invariably takes place at nodes, but many nodes are found in other situations. We have since found that similar preparations have been obtained with Ranvier's silver method by the late Prof. Zimmermann[7] of Bern.

Electrophysiological investigations of peripheral nerves recently made by Huxley and Staempfli[8] and Tasaki[9] have indicated, contrary to earlier opinions, that nodes play an important part in the propagation of nerve impulses. One of the main arguments hitherto adduced against this view is the supposed absence of nodes in the central nervous system. It appears that this objection can no longer be tenable. It is not clear how precisely the nodes of central fibres correspond to those in the periphery, because of the replacement of the Schwann sheath by oligodendroglia in the brain and spinal cord. However, unless the mechanism of nervous conduction differs greatly in different localities, nodes in the brain and spinal cord may have considerable physiological significance.

By the aid of intravenous methylene blue and silver methods, the structure and the distribution of nodes are now being studied with the view of obtaining anatomical data, for example, on the length of internodal segments, which have been pointed out[8] as relevant to the possible physiological role of node formations in the central nervous system.

A Rare Species of Mysid from the Plymouth Area

When my husband, the late Prof. W. M. Tattersall, was examining material collected in the Plymouth area for his work on "The Seasonal Occurrence of Mysids off Plymouth"[1], he found a single adult male specimen from St. *L*.4 belonging to the genus *Heteromysis*. At that time only one species of this genus had been recorded from British waters, namely, *Heteromysis formosa* S. I. Smith. This species, though rare, had been recorded occasionally from Plymouth[2], the Channel Islands and from Scottish and Irish waters. As the male from Plymouth was undoubtedly a *Heteromysis*, it was not examined in detail but was recorded as *H. formosa*.

Shortly before his death in 1943, my husband had occasion to re-examine some of the Plymouth material, and found to his astonishment that the specimen he had recorded as *H. formosa* belonged to the much rarer *H. microps* (G. O. Sars)[3]. Sars first recorded his species under the generic name *Chiromysis*—"the mysis with a hand"—because of the very peculiar prehensile termination of the endopod of the third thoracic limb (= Sars's first leg). His material consisted of a few females only, from the Tunisian Gulf of Goletta, in 6–8 fathoms. Sars at the time was not aware that his new genus had already been described under the name of *Heteromysis* by S. I. Smith[4], who first recorded *Heteromysis formosa* from the North American side of the Atlantic, and he later withdrew the name *Chiromysis* in favour of the earlier *Heteromysis*[5].

Since Sars's original record of *H. microps* the species had never been recorded, nor had the male ever been seen until the specimen from Plymouth was taken. It was my husband's intention to publish a description of this unique specimen and, under his supervision, I made drawings of it. It agrees in the most minute detail with Sars's description and figures as regards general form, eyes, antennal scale, uropods and telson. The endopod of the third thoracic limb has the peculiar prehensile form which is the outstanding character of the genus, but in this specimen it is much more robust than in the females as figured by Sars. This is in all probability a sexual character.

In the hope of finding additional specimens of this interesting mysid, I recently spent some time at the Marine Laboratory, Plymouth, where, by kind permission of the director, Mr. F. S. Russell, I examined collections made in the neighbourhood of the original capture. Unfortunately, no other specimens of the species was obtained. A full description of the male, with figures, will be published shortly in a forthcoming Ray Society Monograph on the British Mysidacea.

Photosynthesis in the Ears of Five Varieties of Wheat

In view of the observations of Knowles and Watkin[1], and of Watson and Norman[2], working with wheat and barley respectively, that about one-third of the final dry weight of the plant is added during the post-ear emergence period, the assimilation by the plant during this period merits special consideration as a factor in determining final yield. The concept of the net assimilation-rate, as originally proposed by Gregory[3], and so successfully used by him and others[4–6] in interpreting problems of crop-growth, would thus appear to require reconsideration, since the net assimilation-rate is usually estimated up to the stage of maximum leaf-growth. After this stage the proportion of green-leaf surface to that of other

* *N.P.* stands for New Pusa, formerly designated Pusa and Imperial Pusa, *P* and *I.P.*, respectively.

green parts diminishes appreciably with time, and the assimilation by the latter might be expected to contribute substantially to ultimate dry matter output. In fact, Boonstra[7], Smith[8], Watson and Norman[2] and Archbold[9] found that, in cereals, assimilation by the stems and by the ears themselves contribute substantially to grain yield.

In the course of work on the physiological analysis of factors determining yield, we have investigated possible varietal differences in respect of the contribution made by assimilation in the ear to grain-yield in wheat. The technique adopted was more or less similar to that of Watson and Norman[2]. The experiment comprised four treatments, namely, control, defoliation (removal of green leaf blades after anthesis), shading the ear and a combination of the last two. All four treatments were included in each pot, there being two shoots per treatment. There were ten replications of each treatment. The calculations were made on the lines adopted by Watson and Norman[2]. From the data presented in the accompanying table, it is concluded that: (*a*) assimilation in the ear contributes considerably more to grain-yield and total plant-weight in *N.P.* 735 and *N.P.* 710 than in the other three varieties; (*b*) the leaf and the ear contribute to total dry weight to the same extent in *N.P.* 710 and *N.P.* 735, whereas in the case of the other three varieties the leaf contributes more to the total dry weight; (*c*) in *N.P.* 165 the contribution of the leaf to total dry weight was, on the whole, the largest; (*d*) as a result of shading the ear, the reduction in 1,000 grain-weight correlated, on the whole, better than reduction in grain-number per spikelet with the differences in assimilation in the ear, which indicates that processes connected with seed setting (fertilization, embryo development, etc.) are not specifically affected; in fact, defoliation also affected seed setting.

It was observed in an investigation on the comparative performances of several varieties of wheat that *N.P.* 710 yielded better than the other three early varieties, *N.P.* 165, Punjab 9*D* and Agra Local, under restricted soil moisture. It is a matter of general observation that *N.P.* 710 and *N.P.* 735 are fairly resistant to black rust, whereas Agra Local and Punjab 9*D* are susceptible, and *N.P.* 165 is only moderately resistant.

It would appear that a variety with ears of high assimilatory capacity would perform relatively better in an adverse environment.

Further investigations are being carried out. Our thanks are due to Dr. B. P. Pal, head of the Division of Botany, for suggesting the choice of varieties and for encouragement.

Oxygen Uptake of *Asterias* Embryos Before Hatching

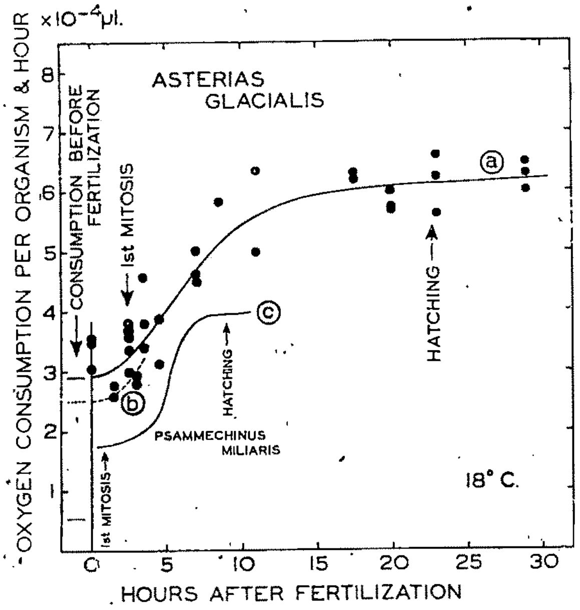
SEA-URCHINS and starfishes differ principally in the oxygen uptake of oocytes and unfertilized eggs[1]; in sea-urchins the respiration of oocytes is higher than that of the eggs, whereas in starfishes the primary oocytes have a much lower oxygen consumption than have the secondary ones or the eggs. In addition, the great increase in oxygen consumption upon fertilization in the sea-urchin egg does not occur in the starfish egg[1-5]. These facts strongly suggest differences in the mechanism of oxidative substrate utilization between the unfertilized eggs of the two groups.

The oxygen consumption of the newly fertilized starfish egg is, however, if measured on a cell-volume basis, remarkably low in comparison with that of the newly fertilized egg of the sea-urchin[1] and of several other marine invertebrates[6]. Thus it might seem that the oxidative mechanism of the young starfish embryo differs from that of the sea-urchin. Probably such a difference would manifest itself in fundamental divergences from the oxygen consumption pattern of the young sea-urchin embryo. Using Cartesian diver micro-respiration technique, the oxygen consumption of this latter has lately[1] been investigated for the time between fertilization and hatching (see also refs. 7, 8).

It has also recently been shown[1] that the exponential increase in oxygen uptake, characteristic of the first few hours of development in the sea-urchin egg[8,1], is roughly applicable to the same time interval in the starfish egg. During this time the starfish egg only passes the first mitosis, whereas the sea-urchin egg reaches the 8- or 16-cell stage. In the present investigation the starfish embryo respiration has been followed for some six hours after hatching.

As previously, Cartesian diver micro-respiration technique at 18° C. was used. In 0·8 µl. of sea-water (32 pro mille salinity) were placed ten eggs or embryos of *Asterias glacialis*, giving pressure differences of approximately 1 cm. per hour. Before fertilization the oocytes were given time to change into unfertilized eggs, that is, time to give off the polar bodies. In *Psammechinus miliaris*, where development to hatching is completed at 18° C. in nine hours, the embryos may, without developmental disturbances, remain inside the diver during the whole of this period. In *Asterias glacialis*, hatching at 18° C. is not completed until 23 hours after fertilization[1]. Moreover, eggs and embryos begin to show signs of dark cytolysis if kept inside the diver for more than five or six hours and simultaneously cease to increase their oxygen uptake rate. Thus divers have to be charged for short-time experiments (not exceeding four to five hours) with material of the different developmental stages, derived from spare cultures maintained at 18° C.

The results are given in the accompanying figure, where each point stands for the mean oxygen uptake of one experiment lasting four to five hours. Uptake before fertilization is denoted, as are the times of hatching and first mitosis (telophase). Curve *a* summarizes the results. In 1947 the uptake values in early development[1] were somewhat lower, as seen from curve *b*. For comparison the corresponding curve for *Psammechinus miliaris* is given in curve *c*.



The method of measurement used necessarily means that biological scattering has greater influence than in the corresponding experiments on *Psammechinus*, where the same embryos could be used throughout[1]. The results obtained, however, undoubtedly show that the increase in oxygen consumption between fertilization and hatching is principally of the same type in both *Asterias* and *Psammechinus*. Thus the results do not indicate that the oxidative mechanism of the young starfish embryo differs from that of the sea-urchin; instead, differences may be anticipated in the oxidative mechanisms of the unfertilized eggs of the two groups.

Cotton Crop Yield in Relation to the Application of Fertilizers

THE authors of a letter under this title which appeared in *Nature* of March 5, p. 362, seem to be unaware how much is known about the manuring of Egypt's chief crop, and about the soil in which it grows.

The Chemical Section of the Ministry of Agriculture is close to the Faculty of Agriculture from which the authors write, and has published a notable and exhaustive series of official bulletins. Most of these are based upon ten-year runs of field experiments at twenty to thirty different sites each year. A list of those available on my shelves is appended.

This work is almost unknown to agricultural scientists elsewhere (having been published locally) and apparently in Egypt also. My present purpose is to direct attention to these comprehensive contributions to soil science which my former colleagues have made.

LEAD ISOTOPES AND THE AGE OF THE EARTH

By Prof. ARTHUR HOLMES, F.R.S.

In his recent discussion of this subject, Prof. Harold Jeffreys[1] suggests two statistical methods for estimating t_0, the age of the earth's crust, from the data on the isotopic constitution of ore-leads of different ages, t_m, provided by Nier and his co-workers[2]. The first of these methods is wrong in principle and yields results which are internally inconsistent and widely at variance both with my own solutions[3,4] and with known geochemical data. The second is sound in principle and leads to results consistent with mine;* but it is wrongly stated by Jeffreys, and the solitary example given is arithmetically incorrect. Jeffreys concludes "that no reliance can be placed on estimates of t_0 that depend on the abundance of Pb^{207}". Since my own estimate depends on the abundances of Pb^{206} and Pb^{207} and I can find no reason for modifying it, it becomes necessary to point out how the alleged discrepancies have arisen.

The atomic abundances of the lead isotopes determined by Nier being nearly what they would be if the primeval lead of the earth's crust had been slowly modified by radiogenic additions[3], it is assumed: (*a*) that a sample of lead separated from an ore of age t_m represents a sample of the rock-lead dispersed at the time of ore formation through the part of the crust from which rock-lead was extracted and concentrated into ore; (*b*) that the isotopic constitution of the primeval lead was constant at the time t_0, when the sialic material of the crust first separated from the body of the earth; the initial atomic abundances of $Pb^{204, 206, 207, 208}$ being 1, x_0, y_0, z_0* respectively; and (*c*) that the corresponding atomic abundances, 1, x_m, y_m, z_m, of the isotopes in a sample of ore-lead of age t_m are given by

$$x_m = x_0 + u\,(e^{\lambda_1 t_0} - e^{\lambda_1 t_m}) \qquad (1)$$

$$y_m = y_0 + v\,(e^{\lambda_2 t_0} - e^{\lambda_2 t_m}) \qquad (2)$$

$$z_m = z_0 + w\,(e^{\lambda_3 t_0} - e^{\lambda_3 t_m}), \qquad (3)$$

where u, v and w are the present atomic abundances (relative to $Pb^{204} = 1$) of U^{238}, U^{235} and Th^{232} in the rock material from which the rock-lead was extracted to form ore-lead; and λ_1, λ_2 and λ_3 are the respective disintegration constants.

From (1) and (2), we have

$$\frac{x_m - x_0}{y_m - y_0} = \frac{139\,(e^{\lambda_1 t_0} - e^{\lambda_1 t_m})}{(e^{\lambda_2 t_0} - e^{\lambda_2 t_m})} = \frac{1}{r}. \qquad (4)$$

Using the relevant data of Table 1 in sets of four, I obtained the following modal solution[4,6]:

x_0	y_0	t_0
10·945	13·51	3,350 m.y. (± about 8–10 per cent).

Shortly afterwards, Houtermans[7] independently published an approximate solution based on the same assumptions, but with somewhat different values for t_m. Since the content of uranium in rocks is generally variable from one region to another, x_m and y_m are also variable in ores of the same age from different regions. If all the assumptions were strictly correct, a plot of x_m against y_m for ores of a given age t_m should be linear, the resulting straight line being what Houtermans calls the 'isochron' for t_m. Two such isochrons for, say, Tertiary–Carboniferous and Pre-Cambrian ores, intersect at a point of which the co-ordinates are x_0 and y_0. Having graphically estimated x_0 and y_0 in this way, Houtermans then calculates t_0 from equation (4). His results are:

x_0	y_0	t_0
11·52 ± 0·60	14·03 ± 0·20	2,900 ± 300 m.y.

No great accuracy is attainable by this method, but the general agreement is of interest.

In the accompanying diagram, x_m and y_m are plotted and the isochrons (corresponding to my solution) are drawn from the point x_0, y_0, which is common to all. The tangent of the angle made by each isochron with the x-axis is r of equation (4), when both variables are plotted to the same scale, and is therefore $5r$ in the present diagram. It will be seen that many of the points fall near the isochrons on which, ideally, they should lie. Few of them, however, fit exactly, and some, especially those of the Joplin leads 9, 10 and 11, and the Austrian lead, 12, are very widely scattered. The existence of such serious departures from the linear relationship demonstrates that in some cases assumption (*c*) does not hold even approximately. This is, of course, only to be expected from a geological point of view. The assumption implies ideal conditions that are unlikely ever to have been realized in the history of any part of the crust. Every region from which lead ores have come must have passed through at least one orogenic cycle, and each time the rock material concerned passed from one cycle to the next—by way of such processes as denudation, sedimentation, metamorphism and granitization—there would be changes in the uranium–lead and thorium–lead ratios. The rather scanty geochemical data available

Table 1

Sample No.	Observed atomic abundances (Nier[2])			Age of ore t_m (m.y.)	Calculated atomic abundances (see text)

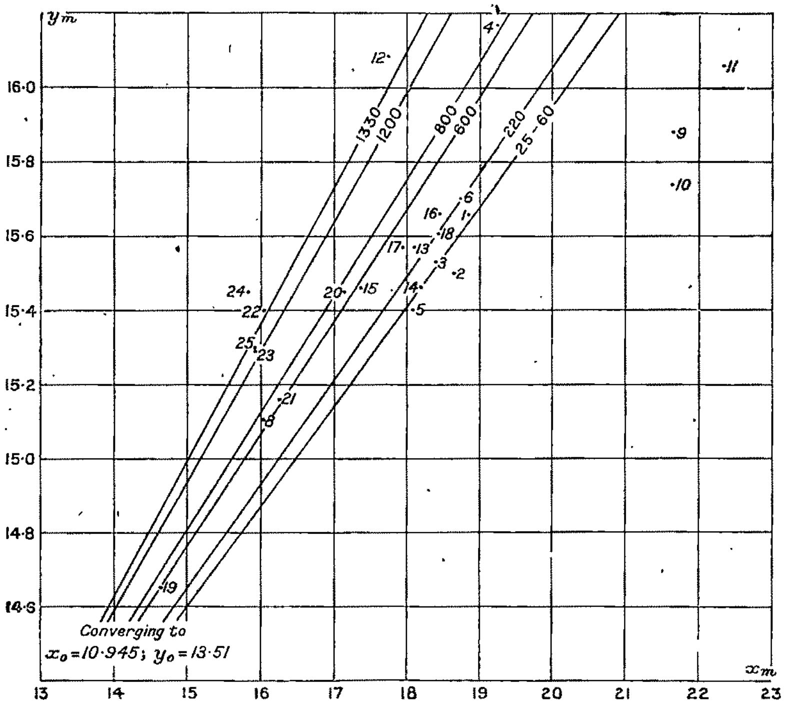
---

* It should be noticed that Jeffreys[1] calls the original abundances 1, *a*, *b*, *c*, whereas I used these symbols for the abundances in ore-leads[3,4]. The symbols now adopted should avoid any possible confusion.



The plotted points are numbered as in Table 1. $x_m = Pb^{206}/Pb^{204}$; $y_m = Pb^{207}/Pb^{204}$. The diagonal lines are the isochrons for various values of t_m (in m.y.) with t_0 taken as 3,350 m.y.

suggests that generally such changes would be quite small and that decreases would be just as likely as increases. For uranium and thorium some of the evidence is collected in Table 2. The general effect of an increase of uranium relative to lead would be to increase Pb^{206} relative to Pb^{207} in the lead eventually evolved, and so to carry a point x_m, y_m to the right of the isochron; with relative decrease of uranium the point would fall to the left. Some slight scatter of the points, not only along the isochron but also on each side of it, is therefore to be expected, and that is, in fact, what we usually find. Locally, however, there might be very considerable changes, and the apparently erratic Joplin (9, 10, 11) and Austrian (12) leads probably illustrate the cumulative effects of one or more such changes. The isotopic constitution of the Joplin lead could have been reached in a great variety of ways, of which the following is an example: modification of x_0 and y_0 in a source-rock with $(u + v) = 10$ until 2,000 m.y. ago, followed by further modification in the transformed source-rock of a later cycle with $(u + v) = 23$ until the time of ore formation. The Austrian lead requires a change of the opposite kind; for example, a source with $(u + v) = 22$ up to, say, 2,500 m.y. ago followed by a transformed source with $(u + v) = 5·5$. Alternatively, the Austrian lead may be a re-precipitation in Triassic times of an old lead ore of age 1,400 m.y. derived from a source with $(u + v)$ about 16·5.

Explanations of the above kinds are offered to account for what Jeffreys[1] refers to as "a disturbance affecting the values for Pb^{207} by $\pm$ 0·2 or so and not associated with the variation of Pb^{206}", and also in justification of my having excluded the Joplin and Austrian leads from my treatment of the problem. These samples, as the isochron diagram shows, do not even approximately conform to the requirements of assumption (c), and consequently no method of estimating t_0 in which they are considered can be expected to yield reliable or consistent results. It should be added that, pending further information, samples 4 and 8 must also be excluded because their age is uncertain. I originally followed the National Research Council Committee[8] in regarding them as Tertiary; but I find that the ore deposits from which they came occur in Pre-Cambrian rocks and may themselves be of Pre-Cambrian age. It seems likely that the 'abnormality' of their x_m/y_m values would largely disappear if their true geological age were known. I originally excluded the Franklin, N.J., sample (20) on the ground that its age could not be assessed. It can now be added to the 800 m.y. group of Pre-Cambrian leads, since it comes from an orogenic belt for which there are two age determinations of 770 and 860 m.y.

Jeffreys divides the samples into four age-groups (*A*, *B*, *C*, *D* of Table 3). No serious statistical discrepancy arises as a result of combining the Joplin lead with the Tertiary leads to form Group *A*, because the three Joplin leads are represented only by their average, and the effect of this is largely balanced by the inclusion in the same group of samples 4 and 8. But in Group *B* the Triassic Austrian lead (12) is combined with the late Carboniferous leads, and it is solely for this reason that Jeffreys finds a negative correlation coefficient for x_m and y_m in Group *B*. If the Austrian lead is omitted, as it should be (see Group *E*), the correlation coefficient for the Carboniferous leads is + 0·69.

Table 2. Uranium and thorium contents of granitic rocks (Senftle and Keevil[9])

Regions	Geological ages	No. of samples	U in p.p.m.	Th in p.p.m.	$\frac{Th}{U}$
1. All outside North America	Wide range	30	4·35	15·2	3·50
2. Ontario and Quebec	Pre-Cambrian	396	2·90	8·89	3·07
3. North-east coast	Mainly Palæozoic	123	4·98	19·8	3·98
4. Eastern States	Palæozoic and some Pre-Cambrian	143	3·40	11·0	3·24
5. Central States	Palæozoic and some Pre-Cambrian	76	3·52	13·1	3·72
6. South-western States	Wide range	50	4·20	13·3	3·17
7. Western States	Mainly Tertiary	52	3·10	11·1	3·58
8. Rocky Mountain States	Mainly Mesozoic	199	4·98	18·7	3·76
9. Central Canada	Old Pre-Cambrian	126	4·68	11·2	2·39
10. British Columbia and Alaska	Mesozoic – Tertiary	92	3·52	12·2	3·47
		Weighted averages	3·82	12·48	3·27

The first method developed by Jeffreys is based on the application of the data for Groups *A–D* (here recalculated in Table 3) to equations (1)–(3). s_1, s_2 and s_3 are the respective standard deviations of the means of x_m, y_m and z_m for a given group; and σ_1, σ_2 and σ_3 are those of u, v and w. If the standard error of u is σ_1, that of x_m is $\sigma_1\,(e^{\lambda_1 t_0} - e^{\lambda_1 t_m})$ according to Jeffreys. If this were true, then (omitting the standard error of s_1 itself, which does not affect my criticism) we could write:

$$s_1 = \sigma_1\,(e^{\lambda_1 t_0} - e^{\lambda_1 t_m}), \qquad (5)$$

and similarly for s_2 and s_3. For each age-group there is such an equation, and Jeffreys solves these equations for σ_1 and t_0, and similarly for σ_2 and t_0, and σ_3 and t_0. The results, as given by Jeffreys, are:

$$\log \sigma_1 = +\,1{\cdot}54 \pm 0{\cdot}26\,; \quad t_0 = 1{,}250 \pm 170 \text{ m.y.}$$
$$\log \sigma_2 = -\,2{\cdot}25 \pm 0{\cdot}33\,; \quad t_0 = 1{,}390 \pm 170 \text{ m.y.}$$
$$\log \sigma_3 = +\,2{\cdot}54 \pm 0{\cdot}26\,; \quad t_0 = 1{,}430 \pm 180 \text{ m.y.}$$

From this it appears that

$$\sigma_1 \text{ is about } 34{\cdot}7\,; \ \sigma_2 \text{ is about } 0{\cdot}0056\,; \ \sigma_3 \text{ is about } 347. \qquad (6)$$

Equation (5), however, would be true only if σ_1 referred to the same group as s_1, whereas in solving the equations it is assumed that σ_1 is the same for all four groups. Actually σ_1 is variable from group to group, just as s_1 is. This can be illustrated from the estimates of u listed in Table 1, calculated from equation (1) with $t_0 = 3{,}350$ m.y. The respective values of σ_1 for groups *A*, *B*, *C* and *D* are found to be 2·21, 0·59, 1·71 and 0·57.

From the data summarized in Table 2 it is possible to estimate at least the order of the real values of σ_1, σ_2 and σ_3 for the variation of uranium and thorium in granitic rocks. To transform parts per million of uranium and thorium into atomic abundances relative to $\mathrm{Pb}^{204} = 1$, the average content of lead (207·2) in granitic rocks may be taken as 21 p.p.m. and the average total abundances as 74. $\mathrm{Pb}^{204} = 1$ thus corresponds to 0·28 p.p.m. of Pb^{204}. Allowing for atomic weights, we find:

$$\left.\begin{array}{l} \mathrm{U} \ = \ 3{\cdot}82 \text{ p.p.m.} \equiv u = 11{\cdot}61 \text{ and } v = 0{\cdot}08 \\ \mathrm{Th} = 12{\cdot}48 \text{ p.p.m.} \equiv w = 39{\cdot}19 \end{array}\right\} \qquad (7)$$

These results for u and v agree closely with those calculated from my solution in Table 1.

The standard deviations of the amounts of uranium and thorium in granites (data of Table 2) are 0·86 and 3·97 in p.p.m., corresponding to:

$$\sigma_1 = 2{\cdot}61\,; \quad \sigma_2 = 0{\cdot}019\,; \quad \sigma_3 = 12{\cdot}68.$$

Variation in the lead content of granites is not likely to increase these estimates, but rather to decrease them, since the elements concerned tend to vary sympathetically in rocks. If, as is probably the case, the ratio of uranium to lead varies less than uranium, and of thorium to lead less than thorium, then the above estimates for σ, etc., would be too high.

It will be seen that the values arrived at by Jeffreys for σ_1 and σ_3 in (6) are not only very much higher than the probable values, but are actually higher than the values of u and w, of which they purport to be the standard deviations. Even allowing for the errors introduced by ignoring the variation of σ_1, etc., from group to group, I find it impossible to understand how the values in (6) can have been extracted from the original data. My own results (cf. 7 and Table 1) are consistent with geochemical data, whereas those of Jeffreys are not. My results (Table 1) give $u/v = 139$, which is the accepted value, but Jeffreys finds $\sigma_1/\sigma_2 = 6{,}160$. Moreover, the results given by Jeffreys for σ_1, etc., and t_0 are internally inconsistent. If the figures in (6) are used to calculate t_0 from equations such as (5), the following results (in m.y.) are obtained:

	$\sigma_1 = 34{\cdot}7$	$\sigma_2 = 0{\cdot}0056$	$\sigma_3 = 347$
Group *A*	320	4,150	120
Group *B*	270	3,900	240
Group *C*	770	3,980	750
Group *D*	1,350	2,570	1,270

whereas Jeffreys gives the following figures for t_0:

$$1{,}250 \pm 170 \quad 1{,}390 \pm 170 \quad 1{,}430 \pm 180$$

I can only conclude that this method is not only wrong in its assumption of a constant σ_1, etc., but that a serious slip has probably been made in the working.

The second method suggested by Jeffreys for finding t_0 is essentially the Houtermans[7] isochron method treated statistically, instead of graphically. From equation (4) we can write:

$$s_1/s_2 = 139\,(e^{\lambda_1 t_0} - e^{\lambda_1 t_m})/(e^{\lambda_2 t_0} - e^{\lambda_2 t_m}). \qquad (8)$$

Jeffreys, in his equation (7), writes, "$\log s_1 - \log s_2$" for s_1/s_2, but this is evidently a slip. Unfortunately, Jeffreys applies this method to Group *A* only and gives $t_0 = 4{,}000 \pm 370$ m.y. as the solution, whereas the correct value is $t_0 = 2{,}870$ m.y. ± about 10 per cent. In Table 3 I have applied the method to groups *A–D* and also to groups *E*, *F* and *G*, from which the 'abnormal' samples and those of uncertain age have been omitted. It will be seen that the average value of t_0 for *E*, *F* and *G* is 3,300 m.y., which agrees closely with my estimate[4] of 3,350 m.y. If the result from Group *D* were also included, the average t_0 would become higher, but Group *D* is not a satisfactory one for the application of this method, because the lead samples concerned have almost identical isotopic constitutions.

Jeffreys writes, "If we accept the smaller values of t_0, or indeed of any value less than 3,000 m.y., the variation of Pb^{207} as between ores of the same age is greater than we should expect from the variation of Pb^{206}". This statement clearly favours a value of t_0 above 3,000 m.y. But Jeffreys continues, "On the other hand, if we adopt a value near 4,000 m.y., we have no explanation of the small scatter of the values for the three oldest ores" (Group *D*). Surely, however, the small scatter is purely a matter of chance and calls for no other explanation. Only two localities are involved, samples 22 and 23 being from Broken Hill, N.S.W., and sample 25 from Great Bear Lake, Canada, and there would be nothing remarkable in the granitic rocks of two such areas having nearly the same uranium, thorium and lead contents. The objection raised by Jeffreys to an age near 4,000 m.y. would be valid only if Group *D* were represented by samples from many localities and still showed a small scatter. As it is, the objection has no weight. Indeed, Jeffreys himself in his final paragraph says it is quite probable "that the small scatter . . . is an accidental agreement". These reasons against the use of Group *D* in this particular method do not apply to my original treatment, because there the data for the Group *D* samples were combined, not with each other, but with those for the samples belonging to groups *E*, *F* and *G*. The method I devised is admittedly a long and tedious one, but it has the advantage of giving a most probable solution, based on all the relevant data, not only for t_0, but also for x_0 and y_0. Meanwhile, I can at least agree with Jeffreys that many more isotopic analyses of old leads would be necessary to improve the estimate appreciably.

MARINE BIOLOGY AT PLYMOUTH

THE latest issue (vol. 27, No. 3) of the *Journal of the Marine Biological Association of the United Kingdom*, again a large publication, provides articles of interest for many tastes in marine biology. There are two papers on fisheries, five on worms, two on molluscs, one on tunicates and one on seaweeds.

Mr. G. A. Steven, writing on mackerel migrations, continues the work published by Mr. P. G. Corbin in 1947. He states the case for depth spawning in this fish, which explains the apparent anomaly that English Channel mackerel migrate *offshore* to an area west of the Scillies in spring, but North Sea mackerel move *inshore* to the deep waters off Norway. The spawning grounds are in both cases near the 100-fathom contour. After the spring spawning the shoals disperse, appear inshore round the southern coasts of Great Britain in the surface waters, and, as winter approaches, congregate on the sea floor in scattered localized areas where there are banks and gulleys.

Mr. P. G. Corbin contributes the ninth in the series "Seasonal Abundance of Young Fish" for the year 1947, and reports that the total of all species of young fish was the lowest yet recorded, "thus fully bearing out the observations of the incomplete year of 1946 and the deductions from the 1939–46 winter phosphate data".

Mr. D. P. Wilson describes the development of *Ophelia bicornis* after artificial fertilization, the first time that the larval development of any member of the family Opheliidæ has been observed. Of interest is the fact that a secretion from the four anal papillæ and the parapodial lobes enables the metamorphosing larva to adhere to solid objects, such as grains of sand. Mr. Wilson considers that the development of *Ophelia* is a typical one among polychætes; it is simple and unspecialized. In a second paper he describes experiments on the metamorphosing larva which indicate that the larva can spend several weeks searching for a suitable substratum on which to metamorphose. It prefers smooth, rounded grains of quartz, uniform in size, and will die if it cannot find conditions as near as possible to its natural habitat when adult. The stimulus to metamorphose is probably tactile, not chemical.

Miss Jean Hanson illustrates specific differences in the genera *Apomatus* and *Protula* by a study of the pattern of the superficial blood vessels on the ventral surface of the thorax, and as a result puts forward the view that *Apomatus* and *Protula* should be combined in one genus, and similarly *Salmacina* and *Filograna*; but she does not suggest which names should be retained.

A new Enchytræid from the beaches of North Wales is described by Helge O. Backlund of Sweden. It has been named *Lumbricillus reynoldsoni* after its discoverer, Dr. T. B. Reynoldson, of Bangor.

Another little-known life-history, that of *Arenicola marina*, has been ably demonstrated by Dr. G. E. Newell. Working on the Whitstable Flats, he collected worms at weekly intervals throughout the year, and found that spawning occurred between the new and full moon in the second half of October, the maximum being at the first quarter, or neap tide. Eggs and sperms were deposited on the surface of the sand at extreme low-water as thin films and milky puddles respectively. The trochophore is demersal, hatching in four or five days after fertilization. It inhabits the *Fucus* zone, and is therefore carried inshore on the tide. Next spring, after metamorphosis, it moves down the beach, and spawns for the first time when two years old. Many worms die after spawning. Discovery of the egg film and autumn spawning settle two questions that have worried marine zoologists for many years.

Prof. C. M. Yonge continues his studies on the structure and function of the mantle cavity in the Mollusca by an account of a shallow burrowing lamellibranch, *Spisula subtruncata*, and a deep-burrowing one, *Lutraria lutraria*. In the former, which inhabits silty sand, the fourth pallial opening for the removal of waste matter from the pallial cavity, just anterior to the inhalant siphon, is provided by slight divergence mid-ventrally of the otherwise closely apposed mantle folds. Long frontal cilia on the gills and a siphonal valve on the inhalant aperture assist in the cleansing operation. In *Lutraria*, a member of the same family, there is a similar waste canal, but the long frontal cilia and siphonal valve are absent.

Dr. Vera Fretter has investigated some of the minute prosobranchs of rock pools, *Skeneopsis planorbis*, *Omalogyra atomus*, *Rissoella diaphana and R. opalina*. In their adaptation to a rock-pool habitat these four molluscs have become highly specialized. The ctenidium and osphradium are reduced in *Skeneopsis* and absent in the other genera; the gut is simple, and the reproductive organs are complex. *Omalogyra* and *Rissoella* are hermaphrodite. The young, hatched from egg capsules in two weeks, crawl about, become mature in six weeks, and reproduce in the same season. All are herbivorous, but assimilate only the cell contents of the plants they consume. They anchor themselves by a mucous rope paid out from the posterior pedal gland. This is an interesting paper with handsome illustrations.

Prof. N. J. Berrill has studied two colonial ascidians, *Stolonica socialis* and *Distomus variolosus*, and as a result considers that the botryllids and the polystelid section of the Styelidæ "exhibiting palleal budding, comprise a natural group". These also are the only ascidians with a photolith, responsive both to light and gravity, in the tadpole phase. He suggests, therefore, a family Styelidæ, with sub-families Botryllinæ and Styelinæ. But the position of *Polycarpa* and other simple Styelids is still obscure.

A welcome new feature is the first of a promised series on algæ. Dr. Mary Parke, commencing with the family Laminariaceæ, writes on the growth of *Laminaria saccharina* from the Devon and Argyll coasts. Her investigations prove that the minute gametophyte is capable of reproduction throughout the year, although the bathymetric level and habitat control its fertility. Sporophytes develop at low levels in spring, summer and autumn, but at higher levels in winter, early spring, late summer and autumn. They can live three years under suitable conditions, with more rapid growth-periods in the first half of each year. The distal frond tissue is cast continuously. Sporophytes first reach maturity at the end of their first year. Dr. Parke is making a type collection of seaweeds from the Plymouth area.

That the Plymouth Laboratory is flourishing is shown by the impressive list of researches now being carried out, by the names of the distinguished visitors who come to it from all parts of the world, and, perhaps not least, by the 83,000 local visitors attracted to the aquarium. The number of members of the Association, however, shows only a slight increase, and might be augmented, with benefit both to the members and to the Laboratory.

Dr. F. S. Russell's lecture on the Plymouth Laboratory, delivered to the Royal Society in March 1947, has been reprinted in the *Journal*, and provides very interesting reading. Both it and the photographs make every marine biologist long to go down to the sea again.

N. B. EALES

UNITED NATIONS EDUCATIONAL, SCIENTIFIC AND CULTURAL ORGANISATION[*]

THE detailed report of the Director General of the United Nations Educational, Scientific and Cultural Organisation on the activities of the Organisation in 1948 could with advantage have been provided with an index, as heads under which the information is supplied—reconstruction, communications, education, cultural interchange, human and social relations, natural sciences—overlap and are not those under which information is necessarily sought. The work of the library, for example, is described under both the first two headings, while much that is of direct interest to scientific workers is scattered under other headings than that of natural sciences. For example, the emergency action taken to deal with the needs of war-devastated countries for books, educational material, and scientific and technical equipment, including the Scientific Equipment Scheme, is described under "Reconstruction", which also records the issue of the second volume of the "Book of Needs", covering surveys mainly in South Asia and the Far East and in Malta, with an appendix including new data on needs in European countries. The international fellowship programmes are described under "Communications". Forty-eight fellowships were awarded at Mexico City in November 1947 in the following fields: science and social development; cinema and radio education; educational problems of war-affected children; librarianship; educational administration; and art and music education. Six fellowships, one in each subject, have been allocated to China, Czechoslovakia, Greece, the Netherlands, Norway, Poland, Denmark and the Philippines.

In accordance with the recommendations of a committee of nine experts from Czechoslovakia, France, the Netherlands, Sweden, the United Kingdom and the United States of America, an International Conference on Scientific Abstracting is projected for June 1949, and the International Federation for Documentation is making a survey of scientific abstracting services on behalf of Unesco. Publications exchange has also been considered, and an approach made to the delicate and complex problems of copyright. Besides the preparatory conference of representatives of universities at Utrecht last August, an interim committee has been set up to develop plans for an international association of universities and like institutions, including an International Universities Bureau. Under the museums programme, advice is being given to museums in member States on exhibitions available for international distribution and on those for which there would be an international demand if they were formed. Questions of methods in political science, the popularization of science and the social implications of science are also receiving attention, while the work of the Field Science Co-operation Offices in Rio de Janeiro, Cairo and Nanking is already proving very successful. Further reference is made to the work of the International Institute of the Hylean Amazon, and an International Conference on High Altitude Research Stations at Interlaken held during August 31–September 3 recommended the establishment by the International Council of Scientific Unions of a mixed commission to facilitate the exchange of information, and that existing high-altitude stations should be organised into a network with additional stations to be established. Besides participating in the preparations for the Scientific Conference on the Conservation and Utilization of Resources in 1949, the Organisation is convening a Technical Conference on the Protection of Nature to be held in June 1949 and has organised a European and African Technical Symposium for the preparatory study of certain regional problems.

Elsewhere, in his general survey, Dr. Huxley refers to the experimental scheme for book coupons covering six countries, to the international summer school for librarians, the creation of the Mass Communications Projects Division, to the need for careful thought on the policy of publications and sponsorship of international publishing activities, and to the importance of the population problem for the tasks of the Organisation.

RAPKINE MEMORIAL MEETING

THE president of the Royal Society, Sir Robert Robinson, presided at a meeting held at the Society for Visiting Scientists on March 9, in memory of the late Louis Rapkine. The chief guests were the French Ambassador and Madame Sarah Rapkine. Mlle. A. Deloyers and Prof. Francis Perrin represented the Commissariat à l'Energie Atomique, and Dr. Magat the Centre National de la Recherche Scientifique; Dr. A. M. Lwoff of the Pasteur Institute, Prof. S. Mandelbrojt of the Collège de France, Prof. J. Hadamard and Dr. A. Mirlès also attended from France.

Sir Robert Robinson said that they had gathered together to give tribute to the memory of a great man whose work was not complete at the time that he died, and whose loss was therefore regretted the more poignantly. He welcomed the French Ambassador and Mme. Rapkine, and their French colleagues.

M. Massigli, speaking in French, said that he came to know Rapkine after he had joined the de Gaulle movement in London, and in his efforts to secure the escape of scientific men from France Rapkine accomplished a great work in fostering Anglo-French scientific relations.

Dr. Joseph Needham spoke of the earlier part of Rapkine's scientific life. He met him first in 1925 at the Marine Laboratory at Roscoff. Dr. Needham said that he and his wife, Dr. Dorothy Needham, were both profoundly influenced by their conversations with Rapkine. He had helped to emancipate them from the insularity of English cultural and social life. Dr. Needham remarked that France was the only country where a young man with Rapkine's unorthodox background could have secured a training in scientific research. His adoption of French nationality was a tribute to French civilization. Rapkine had an extraordinary quality of making people act and live up to the best that was in them. His piercing look made one feel as if one's own conscience was speaking to one, and yet he had such charm that no one ever took offence. His hero was Spinoza, who died at almost exactly the same age of forty-four.

Dr. Lwoff gave an account of the latter part of Rapkine's scientific researches. His early work had led him to the study of the chemical processes of cell division. Gowland Hopkins and Dixon had established that the reduction of oxidized glutathione by tissues occurs only in the presence of soluble sulphydryl groups. Rapkine postulated that cell division is preceded by protein denaturation, which is responsible for the free sulphydryl groups found in the egg. He confirmed these deductions by experiment, and found considerable increases in lactic acid production. He tried to inhibit reversibly the division of the egg. Dickens and Rapkine independently proved that the reaction between glutathione and mono-iodoacetic acid is stoichiometric. The inhibition of cell division by mono-iodoacetic acid was demonstrated in 1937. In the following year Gowland Hopkins discovered that the activity of succino-dehydrogenase is correlated with the presence of sulphydryl groups in the molecule. Independently, Rapkine prepared triosephosphate dehydrogenase and proved that the enzyme is inactivated by oxidized glutathione.

Out of this work came the crowning scientific discovery of his career, namely, the proof, together with Mme. Rapkine and Trpinac, of the protection by cozymase of the sulphydryl groups of dehydrases. In 1939, Gowland Hopkins, the master of British biochemistry, wrote: "His researches have thrown much light on the fundamental phenomena of cell division. They have shown the biological importance of sulphydryl groups. And, directly or indirectly, they have illuminated many other aspects of cell activity. His work is of fundamental importance."

In 1939 Rapkine resisted the temptation to follow up his brilliant researches, and accomplished his destiny by giving to his elected country, during the most tragic period of its history, seven years of a life which was to be so brief.

Prof. Francis Perrin recounted Rapkine's part in rescuing French scientific men after 1940, among whom were himself, and his father the late Jean Perrin, and of how he collected funds in America and found posts for them. He had only recently adopted French nationality, but his loyalty, foresight and moral conduct were an example to his new countrymen. He became the undisputed leader of the French scientific workers in exile, and was not only their chief but also their conscience. None of them would make any decision without his moral approbation.

Rapkine's work for refugees was described by Prof. A. V. Hill. Shortly after the formation of the Academic Assistance Council in Britain in 1933, a similar committee was formed in France. It met with the usual difficulties, and gradually ceased to function. In 1936, a new committee was formed on the initiative of Rapkine. Rapkine had the same difficulties as the earlier committee, and the legacy of its failure, but he overcame them. If he believed in a cause, no obstacle was unsurmountable for him. He had a horror of bureaucracy and a belief in vigorous direct action, qualities which were later to mean life and freedom for a large number of French scientific men and their families. Rapkine started the formation of the international Society for the Protection of Science and Learning, under the presidency of Niels Bohr. His faith, his endless compassion, his integrity and his extraordinary practical sense were an inspiration to all.

Prof. Hadamard referred to Rapkine's sacrifice of years of his scientific life, and the loss of his scientific future. Rapkine had told him after the War that he had devoted years of his life to the rescue of scientific men, and he now would return to science, and acquire—which he thought he could—a great and important scientific authority, and which he would then use for the assistance of great public causes.

Prof. Mandelbrojt described Rapkine's leadership of the French Scientific Mission. He had saved many French scientific workers from concentration camp and death, and had found work for them in America. But none were deeply satisfied. Their souls were not in America but with their colleagues in occupied France. They felt that others were fighting the war for them, and they had a deep desire to join in the fighting for liberation. Many tried to enlist in the army, but were too old or otherwise unsuitable. In 1943 Rapkine visited England and realized the importance for France of a knowledge of the new scientific methods developed during the War, especially of operational research and team-work. He returned to America, and mobilized his group to go to England to assist the British effort in these fields. It was a measure of Rapkine's character that the British authorities were willing to entrust such important new knowledge to him and anyone recommended by him; and so the French Scientific

Mission was able to bring to France at the earliest possible moment much new information on operational research, radar, aeronautics, nutrition and medical research, etc.

Prof. Mandelbrojt ended his address with a proposal for the foundation of an International Rapkine Memorial Fund consecrated to the solution of those problems in which Rapkine had been interested, and to which he had devoted his genius.

Dr. Magat described how in February 1941, when he left as a refugee for America, his state of mind was low, and the future uncertain. When he arrived, the first person he saw was Rapkine, and wherever anyone arrived Rapkine was there to meet them. "It is important," he said, "for them to feel that they are not alone here."

Prof. J. D. Bernal read an appreciation by Prof. P. M. S. Blackett, who had written that Rapkine, in setting up his Mission, had from the very beginning seen more clearly than others the real facts of the situation. He realized what could be achieved, and what not, and he laid his plans accordingly. But vision and intelligence alone would not have led him to the success he attained; what made this success possible were his gifts of character—such a combination of intelligence, persistence and charm, with first-class scientific ability, as are rarely found in one man.

Prof. Bernal added on his own behalf that Rapkine's personality and achievement had been taken too much for granted. We accepted him as part of the atmosphere and of the century. But, in fact, Rapkine was the pattern of the man on which the scientific world of the future will be based.

Mr. J. G. Crowther described how Rapkine joined at an early stage in the founding of the Society for Visiting Scientists. He was a foundation member of the Executive Committee, and the first assistant secretary. In the latter capacity, he was asked to search for a house, with the suggestion that one might be found in Old Burlington Street. Within twenty minutes he returned with news that the present premises of the Society were available and suitable. Mr. Crowther said that Rapkine was sometimes known among his friends as the 'Prophet'. That, indeed, was what he was: leading his people out of persecution, and by his character and example revealing to them the moral law.

Sir Robert Robinson, in concluding the proceedings, described the premature loss of Rapkine as irreparable, and one to be compared with that of Moseley in the First World War. He hoped in particular that Prof. Mandelbrojt's proposal of an International Rapkine Memorial Fund would be instituted.

SOLDERING

MR. W. R. LEWIS, development officer of the Tin Research Institute, recently gave the Institution of Electronics a review of the problem of soldering, particularly those aspects which have led to the continuous-belt technique of soldering articles together, or for making tin-plate boxes, when the mode of heating is with high-frequency currents generated by thermionic-valve plant. The union of metallic surfaces is greatly facilitated by previous 'tinning', that is to say, coating the juxtaposed surfaces with pure tin or a solder, either electrolytically or by hot-dipping; 'tinned' surfaces can be brought very close together and the space between, even if only a few thousandths of an inch, filled with solder, ingress being by capillary action. Thus the making of tin-plate boxes, in which the edges of the pieces are hooked or bumped together, entirely depends on this capillary action, using rings of solder wire, cored with the requisite flux.

The action of the flux is to remove the oxide film. Recent advances include many organic materials which, under the moderate temperatures prevalent in soldering, decompose and release acid, particularly hydrochloric acid, for cleaning the surface. Among these substances are oleic acid, abietic acid (already in resin or rosin), as well as the more frequently used ammonium and zinc chlorides. In the 'activated' fluxes the aim is to produce at the union just sufficient acid to remove the film, so that no appreciable acid is left to give rise to corrosion in damp atmospheres. The choice of flux depends on the metals to be joined, and some fluxes are better than others; for example, phosphoric acid for steel, copper and brass, and lactic acid for iron and brass. The problem with aluminium is to get the tin or solder into intimate contact with the base metal without the oxide film intervening, and this is frequently achieved by vigorous scratching. An alternative suggestion is to build up the oxide film by treatment with phosphoric acid and nitric acid so that it breaks away more easily; the flux then protects the base metal surface while it is being 'tinned' with a high-tin solder.

The art of soldering has been greatly enhanced by the standardized methods of testing solderability, such as the spreading test, the Schumacher–Bouton–Phipps twisted-wire test for capillarity, the Earle test developed in Great Britain during the War for recording the surface pulls across the solder on a kollagraph, and the war-time *D.T.D.* 599 specification. A word of warning must be noted, with respect to the difficulty of controlling the thickness of fine electro-plated films of 'tinning' when large batches of small articles are placed in the electrolytic bath; a considerable factor of safety should be used to ensure a universal minimum.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 21

FARMERS' CLUB (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Prof. W. Ellison: "Reclamation and Use of Marginal Land".

PHYSICAL SOCIETY (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. A. O. Rankine, F.R.S.: "Experimental Studies in Thermal Convection" (Guthrie Lecture).

RATIONALIST PRESS ASSOCIATION (at the Alliance Hall, Palace Street, London, S.W.1), at 7 p.m.—Dr. J. C. Flugel: "Psychology and the Problems of Peace". (Further Lectures on March 28 and April 4.)

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Eric Shipton: "Travels in Sinkiang".

Tuesday, March 22

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. W. E. H. Stanner: "Sociological Problems of the Groundnut Scheme in Tanganyika".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. C. Trevor: "Some Problems of Race".*

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENTS SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Magnetic Amplifiers" (to be opened by Mr. F. H. Belsey).

MANCHESTER GEOGRAPHICAL SOCIETY (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Prof. L. Dudley Stamp: "Alaska".

INSTITUTION OF ELECTRICAL ENGINEERS, NORTH-WESTERN CENTRE (at the Engineers' Club, Albert Square, Manchester), at 7 p.m.—Dr. G. H. Tupling: "The Early Metal Trades and the Beginnings of Mechanical Engineering in Lancashire" (Fourth Annual University Lecture).

Wednesday, March 23

Physical Society, Low Temperature Group (at Petrocarbon, Ltd., Eccles, Manchester), at 9.45 a.m.—Science Meeting.

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Society of Chemical Industry, Nutrition Panel of the Food Group (at Gas Industry House, 1 Grosvenor Place, London, S.W.1), at 6.15 p.m.—Prof. J. Beattie: "The Effect of Non-Protein Calories on the Utilization of Proteins".

Institution of Electronics, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 6.30 p.m.—Mr. S. Rodda: "Photo-Multipliers".

Thursday, March 24

Physical Society, Optical Group (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 3 p.m.—Scientific Papers.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Discussion on "Physics and Chemistry of Hydrocarbon Gels" (to be opened by Prof. E. K. Rideal, F.R.S.).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Discussion on "Animal and Plant Populations in Fresh Water" (to be opened by Dr. T. T. Macan and Mr. D. Le Cren).

Institute of Sociology (at the Royal Institute of British Architects, Portland Place, London, W.1), at 5.30 p.m.—Prof. T. H. Pear: "The Relations between Anthropology, Psychology and Sociology".

Chemical Society, Manchester Section (joint meeting with the Royal Institute of Chemistry and the Society of Chemical Industry, at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—Prof. M. Stacey: "The Chemistry of the Deoxy-Sugars".

Royal Institute of Chemistry, London and S.E. Counties Section (in the Material Research Laboratory, Philips Electrical, Ltd., New Road, Mitcham Junction), at 7.15 p.m.—Dr. J. S. Anderson: "The Chemistry of Semi-conducting Solids".

Friday, March 25

Biochemical Society (in the Department of Biochemistry, University College, Gower Street, London, W.C.1), at 11 a.m.—Annual General Meeting: Scientific Papers.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion.

Manchester Statistical Society, Statistical Methods Study Group (at the Textile Institute, 16 St. Mary's Parsonage, Manchester), at 5.30 p.m.—Mr. A. S. Wharton: "The Organisation of a Market Research Department".

Manchester Statistical Society, Industrial Group (at the Textile Institute, 16 St. Mary's Parsonage, Manchester), at 6.45 p.m.—Mr. N. T. Gridgeman: "Applications of Statistical Methods in Biology".

Sheffield Metallurgical Association, Modern Methods of Analysis Group (at 198 West Street, Sheffield), at 7 p.m.—Mr. J. H. Oldfield: "Solution Analysis by Emission Spectroscopy".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. F. A. Paneth, F.R.S.: "Whence Comes Meteorites? Views Ancient and Modern".

Saturday, March 26

Amateur Entomologists' Society (at Buckingham Gate Central Schools, Wilfred Street, London, S.W.1), at 2 p.m.—Exhibition of Entomological Specimens and Technique, and Lectures.*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer with qualifications in Pure Mathematics, a Lecturer or Assistant Lecturer with qualifications in Applied Mathematics, and a Research Assistant in Mathematical Statistics—The Registrar, The University, Manchester 13 (March 25).

Senior Assistant in Physics—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford (March 26).

Laboratory Technician (male)—The Secretary, Institute of Ophthalmology, Judd Street, London, W.C.1 (March 26).

Assistant Physicist in the Department of Physics applied to Medicine—The Secretary, Middlesex Hospital Medical School, London, W.1 (March 26).

Biochemist to participate in biochemical studies of lactation involving the use of tracer isotopes, and a Biochemist or Chemist to assist in researches in biochemistry of lactation—The Secretary, National Institute for Research in Dairying, Shinfield, Reading (March 26).

Lecturer in Inorganic Chemistry and Metallurgy, a Lecturer in Biology, and a Lecturer in Physics—The Principal, Acton Technical College, High Street, Acton, London, W.3 (March 26).

Assistant in the Science Group of Departments, London Headquarters (to establish and maintain contacts with all branches of the sciences and generally to promote the scientific activities of the Council overseas)—The Director, Personnel Department, British Council, 3 Hanover Street, London, W.1 (March 28).

Travelling Scholarship in Sanitary Science or Municipal Engineering and Hygiene—The Clerk, Chadwick Trustees, 204 Abbey House, Westminster, London, S.W.1 (March 31).

Specialist Advisory Officers in soil chemistry, the chemistry of animal nutrition, entomology, plant pathology and bacteriology, Assistants for field and laboratory work, and Chemists for analytical work on soils, feeding-stuffs and other agricultural materials—The Secretary, Ministry of Agriculture and Fisheries, 1–4 Cambridge Terrace, London, N.W.1, endorsed 'N.A.A.S.' (March 31; overseas, May 14).

Research Fellowship, and a Research Assistant, in the Department of Economics, University of Natal—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (March 31).

Research Assistant (to work under the direction of the research officer in bee-keeping) on field and laboratory problems relating to honeybees and their management—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (March 31).

Senior Scientific Officer or Scientific Officer as Chemist at the Marine Laboratory, Aberdeen, a Senior Scientific Officer as Chemist at the Brown Trout Research Laboratory, Pitlochry, and a Scientific Officer as Botanist at the Brown Trout Research Laboratory, Pitlochry—The Establishment Officer, Scottish Home Department, Room 364, St. Andrew's House, Edinburgh 1 (March 31).

Senior Lecturer in Agriculture, a Lecturer in Poultry Husbandry, a Lecturer in Farm Machinery and Implements, and a Lecturer in Agricultural Science, at the Shropshire Farm Institute, Walford, near Baschurch—The Secretary for Education, County Buildings, Shrewsbury (April 2).

Principal Scientific Officers or Senior Scientific Officers (unestablished) for veterinary research posts at a Ministry of Supply Research and Development Establishment in Wilts—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.8/49A (April 2).

Lecturer or Assistant Lecturer in Botany with special qualifications in Taxonomy, and an Assistant Lecturer in Economic Botany with qualifications in Agriculture or Horticulture—The Registrar, The University, Manchester 13 (April 8).

Derby Chair of Zoology, and a Director of the Marine Biological Station, Port Erin—The Registrar, The University, Liverpool (April 9).

Physicist at the Geophysical Observatory, Wellington—The Official Secretary, Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (April 15).

Lecturer in Child Psychology—The Registrar, The University, Manchester 13 (April 15).

Demonstrator in the Department of Chemistry—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (April 19).

Lecturer in Geology—The Registrar, University College, Hull (April 19).

Lecturers (2) in Mathematics—The Secretary, The University, Aberdeen (April 20).

International Wool Secretariat Scholarships—The Registrar, The University, Manchester 13 (April 30).

Lecturer or Assistant Lecturer in Zoology in the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (May 1).

Director—The Chairman, Coconut Research Scheme, Lunuwila, Ceylon (May 11).

Lecturer in the Mathematics Department—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

Technician (Grade B) with histological experience in the Department of Surgery—The Secretary, Marischal College, Aberdeen.

Qualified Technician or Student Technician in the Biochemistry Department—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Medical Laboratory Technicians (2, one in the Bio-chemical Department and one for the Hæmatology and Clinical Pathology Department)—The Secretary, County Hospital, Lincoln.

Senior Technician—The Regional Transfusion Officer, Southmead, Bristol.

Mathematician (with a first-class honours degree and, preferably, some knowledge of the theory of elasticity) for research in applied mechanics—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Research Assistant (preferably with honours degree in zoology) for research laboratory—The Secretary, South Manchester Hospital Management Committee, Christie Hospital and Holt Radium Institute, Manchester 20.

Studentships in Plant Breeding or Entomology—The Secretary, Empire Cotton Growing Corporation, 1a Harrington Road, London, S.W.7.

Lecturer in Physics and Mathematics at the Municipal Technical College—The Director of Education, Education Office, St. Helens.

Technician at the High Tension Laboratory, Lahore, Pakistan—The Education Authority, High Commissioner for Pakistan, 14 Fitzhardinge Street, London, W.1.

Lecturer in Chemistry—The Principal, Derby Technical College, Normanton Road, Derby.

Senior Lecturer in Chemistry—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3.

PRESERVATION OF THE COUNTRYSIDE

THE National Parks and Access to the Countryside Bill introduced in the House of Commons on March 17 has been long awaited—indeed so long that many despaired of seeing anything done. The appointment of a National Parks Commission, with wide duties, will mark an important step forward.

The announcement by the Lord President of the Council on February 11 of the establishment of the Nature Conservancy followed hard on an adjournment debate in the House of Commons in which the attitude of the Minister of Town and Country Planning had indicated the Government attitude towards Nature conservancy, national parks and the preservation of flora, fauna or scenic beauty. This debate, on quarrying in the Peak district of Derbyshire, on February 7, was admittedly held at an hour when the House of Commons is not normally well attended. Even so, the presence of only half a dozen members was as discouraging to those who are anxious for the effective preservation of Britain's dwindling resources of scenic beauty, flora and fauna as was the reply given by the Minister of Town and Country Planning. Mr. Silkin's inclusion as member of the reconstituted Committee of the Privy Council for Agricultural Research and Nature Conservation may possibly educate him as to the wider issues, but his conversion may have little effect if the House continues to be apathetic to the preservation of amenities or scenic, cultural or scientific values, and is interested only in the economic exploitation of physical resources to the exclusion of considerations of recreation, health and beauty. The New Forest Bill at present before the House of Lords makes no provision for preventing damage to areas of scientific importance. That Bill also contains two clauses which permit the enclosure of a further 5,000 acres for timber-growing and 3,000 acres for agriculture. Strong objection has been made to both clauses as detrimental both to commoners' rights and to public amenity, and it has also been urged that the Bill permits road construction with insufficient regard to amenity.

The occasion of the debate on February 7 was the approval by the Minister of the great extension of the existing cement works in the Hope Valley, an approval which was challenged in forthright terms by Mr. H. Molson, member for the High Peak division, as a grave dereliction of duty. Instead of holding the Peak district in trust against the day when it becomes a national park, the Minister has permitted great harm to be done to the amenities of the Hope Valley. Apart altogether from the merits or demerits of the proposal to insist on the use of something in the nature of the Lodge–Cottrell precipitator to mitigate the dust nuisance as a condition of the extension, or of the possibility of replacing the proposed 400-ft. chimney by a 200-ft. chimney, it is clear that the Minister has neglected the comprehensive examination of mineral development in the vicinity of Buxton and the High Peak which he began in November 1946, and that he has no general plan upon which to work when dealing with individual applications for development which are already alarmingly numerous.

This is the real point of the indictment, which is not wholly met by the Bill just introduced. Mr. F. Marshall, formerly of the Ministry of Town and Country Planning, indicated very clearly the importance of the Hope Valley to the proposed national park of the Peak, and the way in which the cement works is already destroying the beauty of the valley. Protests from the Sheffield and High Peak members were supported by others on behalf of the citizens of Nottingham, Derby and Leicester. In replying, the Minister declined to reconsider his decision; but he stressed the determination of the Ministry to see that in this and in any future workings, not only should restoration be effected so far as possible while working continued, but also the actual working should be carried out in the least injurious manner.

Restoration or palliation, though welcome, is not, however, the particular point at issue. Somewhat injudiciously, perhaps, Mr. Molson had also referred to the great destruction in Ashwood Vale which the Minister is permitting without proper opportunity for public inquiry. This charge was irrelevant to one of dereliction of duty in regard to a national park area; but Mr. Silkin dismissed it all too summarily, particularly in view of the recent transfer from the regional planning controllers to the local planning authorities of the responsibility for notifying interested parties of proposals under consideration. The regional planning controllers have been scrupulous in informing such bodies as the amenity societies at an early stage, and it cannot be too strongly emphasized that early information is essential if such societies are to state their case effectively and advance constructive proposals with the best chance of success.

There is no evidence that the Minister has laid on the local authorities a like responsibility; but what stood out most clearly from this debate is not simply a lack of zeal or will but a lack of power on the part of the Government. The Minister of Town and Country Planning has the invidious, if not impossible, task of being required as a departmental Minister to decide between competing departmental and other claims to the use of land for training purposes, amenities, industry, agriculture, water-supply, mineral workings, housing, etc. He has not the authority to resist the claims of another department, being only *primus inter pares*. The balancing of such conflicting claims can only be done at Cabinet level, and in the absence of such a Cabinet committee as has been repeatedly urged in these columns the piecemeal destruction of Britain's scenic heritage, her flora and fauna and her amenities for recreation and health will continue apace.

There have been repeated instances of this danger in recent months. The Government has approved, for example, the War Department's proposals to use 1,100 acres of land, with a sea danger area, at Ross Links, Northumberland, as an anti-tank gun range, in spite of the proximity of Holy Island, the bird sanctuaries at Ross Links and the Farne Islands and of the historical associations of the district. It is held that the range will not have any serious effect on the bird sanctuaries; but that is a point which might well have been left for the Nature Conservancy to determine. Similarly, the opposition of between forty and fifty local authorities and interested bodies at a public inquiry into proposals by the War Department and the Ministry of Supply to requisition 1,660 acres of Cannock Chase for a Territorial Army training area and a tank-testing ground appears to have been fruitless, departments once again being allowed to judge their own cause.

The decisions announced earlier by the Ministry of Town and Country Planning regarding the War Department proposals for the use of Fylingdales Moor and Redesdale will likewise undermine public confidence in the Ministry's power or determination to safeguard amenity. The area to be used under the former proposal has indeed been reduced by a 950-acre coastal stretch to 28,190 acres; but the application was resisted by all the local authorities concerned, as well as by the National Farmers' Union and the Council for the Preservation of Rural England. The extension of 5,700 acres to the Redesdale artillery range, which has been approved, subject to boundary readjustments and provisions in the interests of ramblers and climbers, cuts across the Pennine Way and into the area proposed for a Cheviot National Park in the Dower Report. This consistent failure of any of the public inquiries into training areas proposed in potential national parks to secure a decision in favour of the objectors only confirms the impression that departments are allowed to judge their own cause.

Nor has the Ministry of Town and Country Planning shown itself any more alert in the defence of villages such as Letcombe Bassett, where what is at stake is the preservation of an ancient village community. The Ministry does not appear to have intervened even to the extent of referring the proposed destruction to its own advisory Committee on Historic Buildings. The security of much of the beauty of the valleys of North Wales, like the continued freedom of the Lake District from overhead lines, has depended on the reasonableness of the British Electricity Authority rather than on any authority or intervention of the Ministry itself. Even such reasonableness has not prevented the formulation of proposals such as that which would have destroyed the beauty of Guy's Cliffe, Warwick, by erecting a generating station at Hill Wootton, although six alternative sites are stated to be available. This particular proposal was promptly repudiated by the British Electricity Authority. The Council for the Preservation of Rural Wales did well to sound a warning, in its annual report, against the idea that the vigilance of its members can be relaxed now that the Town and Country Planning Act has become law. At the annual meeting of the Council at Bangor on January 14, determined but constructive opposition was manifested to features of the power scheme for North Wales, which would turn the Snowdon area into a gathering ground and make a travesty of the idea of a national park.

One of the most encouraging features of the last year is indeed the increasing alertness of the local authorities to the claims of amenity and beauty; and now that the struggle to see that such claims are not thoughtlessly and invariably overridden by the claims of utility is transferred to a new arena, such vigilance will be an important factor in enabling the amenity societies to make effective representations, when the Minister of Town and Country Planning places on the local planning authorities the responsibility which was formerly so scrupulously discharged by the regional planning controllers. This tendency is illustrated by several protests made against the Halifax Corporation Bill, which seeks powers to build a reservoir in the Hebden valley and involves a property only recently given to the National Trust by Lord Savile. The West Riding County Council and the Hepton Rural Council have united with the Hardcastle Crags Preservation Society in opposition which is regional even more than local. Again, at a recent conference to consider the War Department's claims for Angelzarke moors or Hailstorm Hill in Lancashire as training grounds for the Territorial Army, eight local authorities, together with two water-boards and two planning boards, were united in opposition. The second site had the support of the Lancashire branch of the Council for the Preservation of Rural England in a comparative statement. The conference indicated the need for a competent authority, such as the proposed National Parks Commission, at a much higher level which could take an independent view and decide between competitive needs on national and not on sectional grounds.

The National Parks Commission, moreover, should do much to remove the misunderstandings and bitterness which is at present arising between the agricultural interests and those of industry, water-undertakings and urban expansion. The new towns policy and the more effective planning of the use of land has, in fact, already decreased the risk of waste of agricultural land. Nevertheless, the extension of iron ore excavation in Northamptonshire is a source of growing concern to agriculture in a county which has in this way already lost 3,000 acres of rich farm land in the last fifteen years, and has another 60,000 acres threatened by applications in the hands of its planning officer. Here again it is understood that the whole matter is being considered by a committee representing all interests which has been set up by the Minister of Town and Country Planning, and which will have in mind the possibilities of restoration. The steel firms have already joined with the War Agricultural Executive Committee in an experiment which seeks to establish whether a fertile topsoil can be created by the use of artificial fertilizers on a 'valley' site of thirty acres near Corby.

It can no longer be contended that opposition to the proposals for training areas, water-power and other development schemes is factitious and unconstructive. There is no evidence that the Services have ever considered the joint use of training areas, or that in spite of the White Paper any attempt has been made by the individual Services to co-ordinate their own demands. The Minister of Defence has failed, or refused, to use his authority to see that Service demands are properly sifted and co-ordinated before they are submitted to an interdepartmental committee at all; and meanwhile it is evident that the Minister of Town and Country Planning is as incapable of resisting piecemeal demands and encroachment as he is, in the absence of a real policy of industrial location, of giving a clear lead to local planning in such industrial areas as the Hartlepools or the West Midlands.

The publication of the survey and plan for the Hartlepools has strikingly revealed the weaknesses of that aspect. The Government is still attempting to pursue two conflicting and incompatible policies; for whereas the planning of industrial location is essentially a national and regional function, the planning of where people are to live is in the hands of local authorities. Until the Government finally determines which policy for industrial location it means to pursue, and until regional planning authorities are established, much of the excellent work being done by town-planners will continue to be misdirected, and the waste of agricultural land, amenity and scenic beauty will be enhanced.

The absence of a central policy is the real danger in this whole question of national parks, land use and amenity. In its last annual report the National Trust emphatically endorses the view that the stronger and the more independent the national parks commission can be made, the more likely are the national parks to be a success. Furthermore, the Council of that body expresses the hope that legislation to establish a Nature Conservation Board and a Biological Service and to set up the whole organisation for national parks will be based upon the excellent reports from the Hobhouse and the Huxley Committees; a preliminary consideration of the new Bill suggests that, in the main, this has been done.

It is manifestly unfair and unwise to expect local authorities to take a national, or even a regional, view in the administration of national parks, to maintain uniform standards and to resist encroachment of other interests often of more influential national bodies or State departments; but there is no lack of opportunity for local interest and support, if amenity is to be preserved and the national parks and Nature reserves are to serve their purpose. The National Trust in the report already quoted appeals for local support in raising the standard at which National Trust properties all over Britain are maintained, and the report of the Council for the Preservation of Rural Wales, directing attention to the need for a well-informed body of public opinion, notes that in at least three Welsh counties representatives of the Council have already been nominated and accepted as members of the county planning committees.

A number of factors have no doubt contributed to the delay in the appearance of the National Parks Bill, one of them being the apparent lack of decision by the Government regarding the urgency of the situation. Meanwhile, as has been shown above, the piecemeal process of dealing with individual areas as the need arises and with little evidence of any guiding principles has led to encroachment and general dissatisfaction. It is to be hoped that the new Bill will quickly become law, and a strong National Parks Commission be set up which will be able to afford the Minister of Town and Country Planning authoritative advice. Provided he is supported effectively at the highest levels of the Government, and with the aid of the Nature Conservancy and its Biological Service, an important step forward will have been taken towards safeguarding the dwindling reserves of the flora, fauna and scenic beauty of Britain.

A THEORY OF PROBABILITY

Theory of Probability

By Prof. Harold Jeffreys. (International Series of Monographs on Physics.) Second edition. Pp. viii+412. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 30*s.* net.

THE first edition of this now famous treatise appeared in 1939, and the review in *Nature* in the following year by Mr. M. G. Kendall gives a good account of the theory developed by Prof. Jeffreys. I shall therefore give here only a general comment on the point of view adopted in the work, while noting also some of the new features of the present edition.

To many to-day it appears that the classical 'calculus of probabilities' needs to be separated into two quite distinct components:

(1) *The theory of uncertain inference.* This may be described as an extension of traditional logic; in it a probability-number is a numerical measure of the degree of 'reasonable' belief in some proposition, in relation to a given body of evidence. One role of the theory is the provision of a critique of the whole of natural philosophy, and in particular it is relevant whenever a mathematical model is selected for the description of some physical or biological situation, and also whenever a 'prediction' made with the aid of such a model is to be interpreted in relation to one's belief about the real world.

(2) *The theory of chance phenomena.* Not all empirical situations can be appropriately described by mathematical theories of the deterministic type used, for example, in classical mechanics, and sometimes it appears more appropriate to employ a mathematical model involving the notions of random variable and random process. Here a probability-number between 0 and 1 is an ideal element of the model which corresponds in the 'real' world to the value which an observed frequency-ratio appears to be approaching as the number of trials is increased, while a probability-number equal to 0 or to 1 corresponds to 'practical' impossibility, or certainty, respectively. It is these two 'conventions of interpretation' which are used to relate a particular model of this kind to the corresponding empirical situation. The decision to construct such a model for a particular situation will, of course, only be made if the observed frequency-ratios do appear to approach stable values. Accordingly, the fact that the model itself admits a representation of an infinite sequence of trials raises an important question of consistency which is answered satisfactorily by the theorem known as 'the *strong* law of large numbers'.

It follows, if this analysis be accepted, that the theories (1) and (2) should be developed independently; and that (2) shares with every other branch of natural philosophy its relationship to (1). Moreover, (2) will retain its significance even for those who reject some particular (or every) attempt to give a rigid form to (1).

Prof. Jeffreys has provided us with a theory of inference; but he appears to refuse to the mathematical theory of chance phenomena an independent status. This seems to me unfortunate, especially as (2) is more important to the man of science than (1) if he is content to make the inferences relating theory to practice in a manner at once more personal and less formal than that advocated in the work under review.

It might be held that while the notion of chance appears to be an essential element in our description of the world, it is really a reflexion of our own ignorance. If this view is correct, the theory (2) must have its place within the framework of (1); but it would presumably still retain a self-contained validity as a mathematical description of what is observed. Epistemology is likely to lag behind the descriptive achievements of natural philosophy, and accordingly the independent development of a theory of chance phenomena would still seem to be worth while. Prof. Jeffreys, however, will have none of this, for he remarks that "the essence of the present theory is that no probability, direct, prior, or posterior, is simply a frequency".

Of the new features of the second edition of this book, the most interesting is the author's account of his 'theory of invariance'. The aim of this is the provision of a universal basis for the formal description of ignorance needed in the treatment of the problem of estimation by the methods of inverse probability. In the first edition, an unknown location parameter, θ, of unrestricted range was given a prior probability proportional to $d\theta$, while an unknown scale parameter θ of range $(0, \infty)$ was given a prior probability proportional to $d\theta/\theta$. Both the arbitrariness of this procedure, and its lack of invariance for functional transformations of the parameter, have been much commented upon; the theory of invariance goes a long way towards removing one of these objections by providing a rule for the prior probability, which remains unchanged in form for all non-singular transformations of the parameter. The following remarks will illustrate its working in a simple case: let

$$\varphi(x;\,\theta)\,dx \qquad (-\infty < x < \infty)$$

be the probability distribution for a single observation; then if the prior probability for the range of parameter-values $(\theta,\ \theta + d\theta)$ is taken to be proportional to

$$\left\{ \int_{-\infty}^{\infty} \frac{1}{\varphi} \left(\frac{\partial\varphi}{\partial\theta}\right)^2 dx \right\}^{1/2} d\theta, \qquad (1)$$

the required invariance property will obtain, and when the parameter is one of scale or of location the earlier rules follow as special cases.

An extension of the rule to multi-parameter problems is given, but Prof. Jeffreys stresses the need for further investigation. It seems likely that the methods he has introduced here will also suggest interesting developments in other approaches to the problem of estimation; thus the integral occurring in (1) plays an important part in Prof. R. A. Fisher's theory of 'statistical information', while (following suggestions by Diananda and Perks) some comments are made in the present work on the relation of maximum likelihood to invariance theory.

The book concludes with a number of new tables and with an appendix on the consistency of the product rule. The first edition contained a very useful appendix on the properties of the factorial (that is, gamma) function; this has been omitted, but an equivalent account has been published separately (in "Methods of Mathematical Physics").

Only to those few who are not familiar with the 1939 edition need it be said that this is a profoundly interesting book of the greatest originality. No one who is seriously interested in the subject can afford not to read it. DAVID G. KENDALL

A TEXT-BOOK ON FUNGI

The Fungi

By Frederick A. Wolf and Frederick T. Wolf. Vol. 1. Pp. x + 438. 36s. net. Vol. 2. Pp. xii+538. 39s. net. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, 1947.)

THERE is a great demand among university students in botany for modern text-books dealing with the fungi. Broadly speaking, two works are needed: a relatively small book dealing briefly but clearly with the morphology and reproduction and also discussing the physiology, ecology and cytogenetics of fungi, and a larger work, probably running into several volumes, dealing with the structure, reproduction and taxonomy of fungi along the lines of Fritsch's classic on algæ.

The publishers' announcement heralding the appearance of F. A. Wolf and F. T. Wolf's two volumes led many teachers of botany to hope that this new work would satisfy a very real want; unfortunately, the books have proved a disappointment. Volume 1 is so different from volume 2 that a reviewer must treat them separately. The former aims at giving the student a picture of the developmental morphology and classification of fungi. Clearly, in 438 pages it is not possible to be exhaustive, and the authors have deliberately omitted certain families; but the omission of all reference to Drechsler's beautiful work on Zoopagaceæ and to Winge's classic researches on haplophase and diplophase in yeast are difficult to excuse.

It is the modern fashion to condemn the 'type' method in teaching, and certainly Wolf and Wolf are modern in this respect. From their book it would certainly be very difficult for the student to gain any really clear picture of the structure and life-history of any single fungus. This difficulty is increased by the fact that the numerous black-and-white illustrations are merely scattered about the text as decorations, the authors having deliberately refrained from making reference to them in the text. Perhaps the best part of volume 1 is the treatment of the Ascomycetes; but in the Basidiomycetes the Hymenomycetales are dismissed in twenty pages and, instead of a careful comparative account of structure and development, the student is presented with a very inadequate discussion of the characters used in the delimitation of genera. Again, the section on Phycomycetes leaves much to be desired, and there are errors both in the figures and in the text. We are told that the chytrids are characterized by anteriorly uniflagellate zoospores; bi-flagellate zoids are seen escaping from the zoosporangium in Fig. 22 which represents *Blastocladia*, and the structure of the sporangium of *Rhizopus* (Fig. 35) is distinctly odd.

The mycologist having perused volume 1 turns with relief and hope to volume 2, since the list of chapter headings gives real promise. This volume consists essentially of a series of essays on mycological subjects, such as: nutrition of fungi, biochemistry of fungi, spore dissemination, germination of spores, host penetration, physiological specialization, mycorrhiza, genetics of fungi, poisonous and edible fungi, medical mycology, soil fungi, fungus-insect relationships, marine fungi and fossil fungi. Each essay has a good list of literature at the end, and these lists probably represent the most useful part of the whole work. But the essays themselves are disappointing, and errors are easy to find. It would have been better had the authors discussed fewer topics in a more careful and discriminating manner.

The volumes are well printed, strongly bound and the text-figures are clear; but, even if the work could be recommended to students, the price is much too high. C. T. INGOLD

SELECTED PAPERS OF C. O. JENSEN

Selected Papers

By C. O. Jensen. (Published at the expense of the Rask-Ørsted Foundation.) Vol. 1: 1886–1908. Edited by M. Christiansen and H. O. Schmit-Jensen. Pp. xvi+681+14 plates. (Copenhagen: Einar Munksgaard, 1948.)

THIS collection of papers represents the scientific activities of C. O. Jensen during 1886–1908, and is to be followed by a second volume covering the period 1909–33. Thirteen of the papers which were originally published in Danish have been translated into excellent English. The remainder are reprints in German and one in French.

Most of the work was done in the Bacteriological Department of the Laboratory for Agricultural Research, Copenhagen. A short biography, in English, by M. Christiansen, adds point to the collection. A period of three years illness forced Jensen to give up his veterinary practice and take a sedentary job in bacteriology, and this greatly influenced his scientific career. He was fortunate in having for his teachers Salomonsen, who also trained Fibiger, with whom Jensen was associated in several investigations, and for a time in Berlin, Robert Koch.

Jensen succeeded Bang, and for forty-five years lectured on bacteriology and serology. Living at a time when bacteriology was making rapid strides, it is not surprising that Jensen was able to produce a great many valuable papers on milk control and various animal diseases. To the medical reader, the greatest interest probably will centre on his advocacy of pasteurization and hygiene in the dairy industry. Jensen identified the causes of the turnip flavour in milk and butter, which he showed to be due not, as then believed, to the cows' diet but to contamination of the milk after milking by various specific bacteria. He saved the Danish dairy industry a great deal of money, and made notable contributions to public health and to veterinary science. A period of collaboration with Fibiger helped to establish the relationship of human and bovine tuberculosis. To the writer, however, Jensen's work on experimental cancer is of the greatest interest. This subject is covered by six papers, five of which are translated into English from the original Danish.

Jensen established a number of transplantable tumours of mice and a transplantable sarcoma of the rat, generally called the 'J.R.S.', which is still widely used because of its consistent biological characteristics.

Many of the now well-known properties of tumour cells were first described by Jensen, who showed experimentally that they could not resist temperatures above 46° C., actinic light from a Finsen lamp with adequate cooling of the tumour tissue, drying and autolysis, and, in fact, that cancer cells had general properties very similar to those of normal cells. He failed to demonstrate any infective or parasitic causal factors associated with his transplantable tumours. In a lecture on "Some Experiments with Cancer Tumours" in 1901, Jensen discussed the etiology of cancer in terms that are equally apposite to-day.

Jensen's objective attitude towards his own work is well illustrated by his frank admission in a paper (1908) that his earlier claims, in 1905, to have caused regression of transplanted tumours by injection of antiserum obtained from rabbits immunized against mouse tumour were ill-founded, and that the regressions were probably spontaneous.

Jensen recognized the desirability of investigating the incidence of spontaneous tumours in the progeny of mice bearing spontaneous tumours. He attempted some experiments on these lines; but as the significance of line breeding was not then appreciated, his results were less striking than those of modern geneticists.

This collection of papers is an example of consistently good experimental work, lucidly expounded.

P. R. PEACOCK

SPECTROSCOPY AND ITS APPLICATIONS

Spectroscopy and Combustion Theory

By Dr. A. G. Gaydon. Second edition, revised. Pp. xii+242. (London: Chapman and Hall, 1948.) 25*s*. net.

Hyperfine Structure in Line Spectra and Nuclear Spin

By Prof. S. Tolansky. (Methuen's Monographs on Physical Subjects.) Second edition, revised and enlarged. Pp. viii+120. (London: Methuen and Co., Ltd., 1948.) 6*s*. net.

BOTH these books are revised second editions of well-known and valuable monographs. They deal with the detailed application of experimental and theoretical spectroscopy to the specialized problems of chemistry and physics. Both are written by acknowledged authorities in their respective fields, and contain fairly complete reviews of the original contributions of the authors.

Combustion processes are extremely fast chemical reactions, and kinetic studies have shown that many are chain reactions involving the intermediary participation of atoms, radicals or energy-rich molecules. Direct measurements of the nature, formation and reactivity of these active particles are not straightforward, and it is in this field that spectroscopic studies can reveal much information not obtainable in other ways. In his monograph, Dr. A. G. Gaydon has summarized the progress that spectroscopic research has made in the study and elucidation of the finer details and mechanism of the combustion process. Much of the material is the original work of the author, and in preparing the second edition the book has been considerably expanded and brought up to date by the inclusion of new material. Those who found the first edition valuable will not hesitate to read this new modernized version. To others interested in combustion the book can be warmly recommended as a most stimulating work and the only book which summarizes the great advances which the application of theoretical and experimental spectroscopy have made to the theory and nature of combustion. The subject-matter is presented in an elegant, precise and readable manner, and no detailed previous knowledge of spectroscopy by the reader is assumed. The early chapters, which deal with the study of the emission spectra of various flames and explosions, are followed by chapters devoted to continuous spectra, the role of atomic oxygen in flames, and the use of absorption spectra and investigations in the infra-red region in studying combustion processes. Later chapters are devoted to special topics such as after-burning, determination of flame temperatures, and the life-time of activated molecules. In the last section the author indicates possible future developments and the nature of the problems yet to be elucidated. A fairly complete bibliography and an appendix, giving the chief characteristics of the flame spectra which have been studied, are included and have enhanced the value of the work as a reference book.

Prof. S. Tolansky's small book is one of the well-known series of monographs on physical subjects published by Messrs. Methuen. It is intended for students who are already familiar with the fundamentals of atomic spectroscopy and who wish to enlarge their knowledge and become familiar with the important developments which have arisen from the detailed study of the theoretical and experimental aspects of the hyperfine structure of line spectra. Since the first edition of this work, considerable advances have been made, and these are included in several new chapters and by the extensive rewriting of other sections of the book. Because the hyperfine structures of the spectral lines are due to either isotopic mixture or spin properties of their nuclei, recent developments have been largely concentrated on providing information about nuclear and magnetic moments. It is with this aspect that the book is mainly concerned. The determination of these magnitudes is summarized in a clear and concise manner, and an up-to-date list of nuclear data of some fifty-five different atoms, including seventy-nine isotopic species, is provided and discussed. An adequate theoretical background for the understanding of the hyperfine structure is given.

The advanced student or others interested in either spectroscopy or nuclear structure will find this book easily readable and useful. It can be thoroughly recommended as an excellent introduction to the subject.

The Cinnamon Bird

By R. M. Lockley. Pp. 79+4 plates. (London: Staples Press, Ltd., 1948.) 8*s.* 6*d.* net.

R. M. LOCKLEY is one of the best-known of British naturalists. He is an accurate observer, and his prose is so good that any book of his is pleasant to read, even by those who have little knowledge of the subjects on which he writes. In "The Cinnamon Bird" he tells of an experiment made of taking a dozen marked canaries from captivity to his small, wind-swept island of Skokholm in the Irish Sea, a home of shearwaters and an alighting place of many migrants. Here the small birds were gradually given full liberty, and the record of their lives on the island during the spring, summer and autumn is set down. By September the population of canaries had increased, and the young birds flew over the island in little flocks or 'charms', happy and carefree. But in September came disaster, for the island is visited each year by numbers of sparrow hawks, and these gradually thinned the numbers of the canaries until those which were not caught and housed once more had all been killed. One of the canaries had a brief mating with a migrating goldfinch, which next morning left the island. She laid four eggs, but only one hatched. The hybrid was a cock, a beautiful and strong bird, with a rich song differing slightly from a canary's song. One of the most moving passages in the book describes the son's furious pursuit of the hawk which killed his mother. There are four excellent illustrations in colour by C. F. Tunnicliffe, which are admirably reproduced, and the printing and appearance of the book generally are unusually good. In this short notice I have been able only to touch on the book's contents, which will be read with appreciation by R. M. Lockley's wide circle of admirers. SETON GORDON

Compendio y descripción de las Indias occidentales

Por Antonio Vázquez de Espinosa. Transcrito del manuscrito original por Charles Upson Clark. (Smithsonian Miscellaneous Collections, Vol. 108: Publication 3898.) Pp. xii+801. (Washington, D.C.: Smithsonian Institution, 1948.) n.p.

THIS thick volume is a transcription of an unidentified manuscript found in the Vatican by Mr. C. U. Clark in 1930 and afterwards ascribed without any doubt to the Carmelite Fray Antonio Vázquez de Espinosa. Mr. Clark edited it and translated it into English, and this version appeared in 1942 as vol. 102 of the Smithsonian Miscellaneous Collections. It proved impossible to carry out the editor's original intention of publishing the Spanish text opposite the translation, and its appearance six years later cannot but be somewhat of an anti-climax to English readers. The work itself is a description, mainly geographical in the widest sense, of Central and South America and the Philippines, and it includes matter for the anthropologist, the botanist and the historian; however, the author does not claim special historical knowledge—in fact his remarks about the Inca Atahuallpa show less of knowledge than a desire to vindicate his countrymen. The editor considers that the greatest value of the work lies in the picture it gives of contemporary Spanish colonial and ecclesiastical administration at a period which is not adequately covered by other writers.

The book was written in 1628, and internal evidence shows that Vázquez's travels lasted over at least the years 1612–21. He gathered much of the information himself, covering a surprising amount of country in lands where travel has always been difficult and full of hardship. He was at pains to learn from eyewitnesses about regions which he could not visit, and his information, though necessarily variable in the amount of detail given, rings true in the ears of a modern traveller who knows a few of the places he describes. G. H. S. BUSHNELL

Some Notes on the Psychology of Pierre Janet

By Elton Mayo. Pp. ix+132. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1948.) 14*s.* net.

IN his researches into human problems in industry, Prof. Elton Mayo has been considerably influenced by the work of Pierre Janet, the French psychologist. Janet's findings have been less well known in the English-speaking countries than on the Continent, since few of his important works have been translated into English. To help those who wish to read Janet in the original French as an aid to their studies of society or of industry, Mayo has brought together some notes which were originally prepared for his colleagues at the Harvard Graduate School of Business Administration whose work demanded close attention to the difficult individual, social and administrative problems of our time. For many years Janet's clinical contributions to psychopathology have been dismissed somewhat cavalierly as something which has been superseded by Freudian and other developments. Readers of these notes will find that there is little real conflict between the observations of Janet and Freud, and that Janet's investigations into the restricted field of obsessive thinking are in many ways mutually complementary to Freud's more widely ranging hypotheses. The book, written with Mayo's usual enthusiasm and sincerity, also includes his address to the Harvard Medical School on "Frightened People", in which he describes the causes of fear in individuals and the need for effective re-assurance in the consulting room. T. H. H.

Proteins and Amino Acids in Nutrition

Edited by Dr. Melville Sahyun. Pp. xvi + 566. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1948.) 45*s.* net.

THIS collection of articles, by various experts, some of them having the standing of international authorities, covers a wider field than one could infer from its title. It is a long way from the feeding of pregnant women to the size of particles found in rabbit papillomas. The only connexion is that both have a *p* in them, the *p* standing for protein. This is essentially a book for libraries and is in some ways an essential book for libraries; many who cannot be expected to pay its rather high price for very occasional use will want to consult it from time to time, until the day when, like all such compilations, it has become too out-of-date to have anything but historical value. This will be small, for it bears no impress of individual personality or even of editorial policy; it is rather a friendly symposium, at a high technical level, unhampered by fear of the chairman's gavel. Names such as H. H. Mitchell, Lela Booher, H. J. Almquist, Clarence Berg and the editor himself guarantee, however, that the contributions to the symposium will—etymology notwithstanding—be full of meat. From the British reader's point of view, however, the 94 pages of appendix are almost complete waste of space. A. L. B.

PIERRE SIMON LAPLACE (1749–1827)

By Dr. S. LILLEY

St. John's College, Cambridge

DESPITE the immensity of his achievement, Newton had scarcely done more than pose the problem of explaining the observed behaviour of the solar system in terms of his laws of motion and the inverse square law of gravitation. Until the full complexities of the observed behaviour of the planets and their satellites had been shown to be deducible from the Newtonian laws, philosophers might (and sometimes did) doubt whether gravitation alone was a sufficient principle of explanation in celestial mechanics. The task of completing the Newtonian celestial mechanics was largely carried out in the century after Newton's death by French mathematicians, and above all by Laplace.

Of Laplace's great book, Grant remarked, "The physical theory of the planetary system is exhibited in the *Mécanique Céleste* in a state of almost complete development"[1]. There were details to be filled in, of course—even some that required prodigious efforts of thought and calculation, like the explanation of Saturn's vagaries by the prediction of Adams and Leverrier in 1845–46 that they were caused by a yet undiscovered planet, Neptune. There were mistakes to be corrected—a fortuitous coincidence with observation, which Laplace had obtained by neglecting non-negligible quantities in his explanation (1787) of the moon's secular acceleration in terms of the changing ellipticity of the earth's orbit, was only pointed out by Adams in 1853. But by and large, Grant's assessment is correct, provided we substitute the word 'Newtonian' for 'physical' in the sentence quoted; for the main nineteenth-century advances were made by taking into account physical phenomena—such as tidal friction—not contemplated in a purely Newtonian scheme. It was by tidal friction that the error regarding the moon's secular acceleration, for example, was eventually cleared up by Delaunay.

Pierre Simon Laplace was born of a Normandy peasant family on or about March 23, 1749, and died on March 5, 1827. There is sufficient of a seamy side in his personal and political life (for, like many French scientific men of his times, he took part in politics during and after the Revolution) to make it advisable in a short note to give no more of his biographical details.

The scope of Laplace's astronomical work makes it impossible to do more than mention some of his contributions. With Lagrange, he accounted for most of the outstanding planetary inequalities. His improvements in the lunar theory were immense—particularly the entirely new mode of treatment which he introduced in the third volume of the "Mécanique Céleste". Even his only partially correct explanation of the moon's secular acceleration was a great achievement, since the problem had baffled others so completely that Lagrange, for example, had been led to doubt the observations. He took a first step towards Maxwell's elucidation of the structure of Saturn's rings when he showed that they could not be uniform solid bodies. He introduced a dynamical theory of the tides, an enormous advance on the statical theories that had preceded it, though still inadequate to describe the physical realities of tides on so complicated a surface as that of the earth.

But Laplace's most impressive achievement was the series of researches, conducted in competitive co-operation with Lagrange, that led to the demonstration of the stability of the solar system. Beginning in 1773, these researches passed through such steps as the explanation of the inequalities of Saturn and Jupiter, to the two following remarkable propositions:

(1) Take for each planet the product,

$$\text{mass} \times \sqrt{\text{axis of orbit}} \times (\text{eccentricity})^2.$$

The sum of these products over all planets is invariable.

(2) The proposition obtained from (1) by substituting the tangent of the inclination of the planet's orbit for its eccentricity is likewise true.

In each case the truth of the proposition depends on the fact that all the planets revolve in the same direction around the sun. Since both these quantities are known to be small at the present epoch, it follows that, under Newtonian assumptions, the eccentricities and inclinations must always remain small. In other words, the solar system will continue indefinitely in something closely approaching its present form.

In his "Mécanique Céleste" (1799, 1802, 1805, 1825), Laplace gave an exposition of all existing knowledge of physical astronomy. The book exhibits the solar system as a vast and complex machine, every movement of which is a mere working out of the laws of mechanics and gravitation, while its continued functioning for an indefinite period is guaranteed by the two propositions on stability referred to above. Napoleon, according to a favourite story, remarked to Laplace that God was nowhere mentioned in his work; and Laplace replied, "Je n'avais besoin de cette hypothèse-là". It was this aspect of Laplace's work that most struck his contemporaries. An age that was still dominated by natural theology could not but be shocked at the idea of a universe so perfectly mechanical as not to require Providential intervention to ensure its continued working, or at least special planning by the Creator at the time of creation to ensure that the machine would work indefinitely. Astronomical treatises of the time, and especially popular and semi-popular presentations in encyclopædias and the like[2], devote much space to showing that Laplace has not abolished the 'argument from design'—the fact that the demonstration of stability depends on the rotation of the planets all in one direction is taken as an argument that they must have been designed to do so; the inverse square law is somewhat heatedly asserted to be a matter of Providential design and not, as Laplace and others would have it, an essential attribute of central forces; and so on.

This opposition emphasizes one of Laplace's more general contributions to thought: his enormous astronomical achievements were among the most important of the factors which slowly drove teleology out of science during the course of the nineteenth century. (On the negative side, the success of celestial mechanics must bear a share of the blame for the extreme mechanistic attitude that permeated later nineteenth-century physics.)

Another contribution to this wider sphere of thought came from Laplace's nebular hypothesis for the origin of the solar system, which he propounded only half seriously in his "Système du Monde" (1796). Inadequate to explain the actual facts, it nevertheless helped to establish the conception of a universe which evolves historically through long periods of time, in place of the static, unhistorical world-view that had hitherto dominated European thought, with its correlative belief that the world was only a few thousand years old. The nebular hypothesis took its place along with the first significant attempts at evolutionary theories in geology (Hutton, 1785) and in biology (Erasmus Darwin, 1794, and Lamarck, 1801) in making the first breaches in this unhistorical universe. (The almost simultaneous appearance of these three theories is probably not entirely independent of the ideas about social evolution that became common before and during the French Revolution.)

Laplace did little in experimental science. He did, however, collaborate with Lavoisier in researches (published in 1784) which rank second only to those of Joseph Black in the foundation of calorimetry, and which led to the first clear conceptions of the relations between combustion and respiration.

On the other hand, he played an important part in the first stages of the development of mathematical physics (as contrasted with mechanics), which was to burst forth in full vigour with the work of men like Fourier, Poisson and Fresnel a few years later. Some of the beginnings of this new movement can be traced to Laplace's theory of capillarity (1805, independently developed by Thomas Young about the same time), his correction of Newton's formula for the velocity of sound (by making allowance for adiabatic compression and expansion), and his less fortunate attempts to give satisfactory mathematical formulations to the corpuscular theory of light and the imponderable fluid theory of heat.

It is the common fate of great men that their more concrete scientific contributions soon find their way into the attic store-room of 'mere history', because they are quickly superseded; while their more abstract methodological contributions may survive for centuries as the working tools of future generations. Laplace's not negligible work in such practical matters as navigational astronomy had only a short-term significance and is now almost forgotten (though the metric system constantly reminds us of another practical matter in which he took part). Much of his astronomy has also now become mere history: what, for example, can be the significance of his demonstration that the abstract universe with which he dealt is stable, when we know that the physical universe includes important phenomena like tidal friction which his work ignored? But some of the mathematical tools which Laplace invented or developed in the course of his researches came to be among the everyday working tools of mathematical physicists, and remain so to-day.

Laplace had almost no interest in mathematics as such. It was to him just a tool for solving physical problems. Hence his mathematical style was far from elegant, and often very obscure. It is, furthermore, difficult to distinguish precisely his own mathematical discoveries, since he borrowed unashamedly without acknowledgment. The concept of potential he got from Lagrange, and even the famous 'Laplace's equation', $\nabla^2 V = 0$, where V is the potential, occurs in hydrodynamical researches by Lagrange so early as 1760. But it was Laplace's use of these tools in gravitational problems that demonstrated their power, so that the attaching of his name to that now ubiquitous equation is perfectly justified. He also made notable contributions to the special functions occurring in boundary-value problems. In fact, many of the partial differential equations that became important in the nineteenth century and much of the mathematics of boundary-value problems arise directly or indirectly from Laplace's work. From the potential theory one can trace, for example, a connexion to Riemann's special approach to the theory of functions of a complex variable, and thence to one of the sources for the development of topology. In similar ways one could, if the search were worth the trouble, find part of the sources of much nineteenth-century mathematics (which the twentieth century still uses) in the work of Laplace. Another mathematical tool still in everyday use is Laplace's rule for the expansion of a determinant, which he gave in a clumsy form in 1772.

Laplace's work on the theory of probability was again derivative in the first place from his astronomical work; but in this case he did go on to develop it for its own sake ("Théorie Analytique des Probabilités", 1812). This is usually considered as the greatest contribution by any one man to probability theory. Laplace had earlier discovered the normal error law. But his most important advance is his consistent and extensive use of continuous probability distributions, which had made only rare and sporadic appearances with previous writers. It is this point especially that entitles his book to be called the first presentation of something like a modern theory of probability in connected form.

---

[2] For example, "Pantalogia, A New Cyclopædia" (London, 1813), article "Astronomy", cols. 13–14. I merely cite an example which happens to be on my shelves at the moment of writing.

SCIENCE AND DEVELOPMENT IN THE PACIFIC AREA

By Sir NORMAN HAWORTH, F.R.S.

THE Seventh Pacific Science Congress met at Auckland and Christchurch, New Zealand, during February 2–22, under the auspices of the Royal Society of New Zealand and its president, Dr. R. A. Falla, who presided over the Congress. The secretary-general was Dr. Gilbert Archey, director of the Auckland Museum, and Prof. R. S. Allan was chairman of the Christchurch committee. The New Zealand Government extended invitations to forty-eight countries represented in the Pacific Science Association, to the South Pacific Commission and Health Service and the specialized agencies of the United Nations and the Economic Commission for Asia and the Far East. About 220 delegates attended from overseas, and some 150 from New Zealand. Earlier Congresses have been held in Hawaii (1920), Australia (1923), Japan (1926), Java (1929), British Columbia (1933), California (1939). Their purpose has been to initiate discussions on scientific topics of special significance to the Pacific area and of importance to the welfare of its peoples. Sessions of the present Congress were devoted to discussions of major problems, particularly those demanding close co-operation between sciences and between countries, and the formulation of further research plans required to secure these aims.

In the Geology, Vulcanology and Geophysics Section, a remarkable colour-film was shown of the birth and development of a new volcano rising from the agricultural plain at Paricutin in Mexico. In a few months this volcano, amid its fringe of hot flowing lava and dust, attained a height of 1,400 ft. above the plain and submerged a village. Beno Gutenberg, of the Seismological Laboratory at Pasadena, presented a map showing the Pacific basin surrounded by volcanic and seismic activity. A systematic relationship was found between the distribution of the gravity field, deep sea trenches, island areas, and foci of earthquakes. One session was devoted to recent work on cosmic noise. E. G. Bowen gave an account of radio noise coming from the region around the sun, and suggested that the temperature of this region rises rapidly with increasing distance from the sun.

Weather forecasting in the tropics and the mechanism of typhoons were the subjects of several papers in the Meteorology Section. If a sufficient number of tropical weather stations were available, one of the most fruitful methods of forecasting would be to measure the convergence of surface winds with the view of finding where the air was rising. Major W. S. Barney, of the U.S. Air Force, described how, during a recent typhoon which swept over the Philippines, weather reconnaissance squadrons determined its centre from day to day during December 2–10, 1948. They found that at 10,000 ft. they were above the violent part of the storm. In the centre was a calm circular area some twenty miles in diameter in which the sky was clear. Descending into this area to 1,500 ft. they saw the clouds in the form of a vertical wall around them. They flew into this cylindrical wall and encountered such violent up-currents and turbulence that their aircraft was damaged despite its great strength. The physical features which determine the course of tropical cyclones were discussed. From an analysis of upper air data, R. H. Simpson, of the U.S. Weather Service, suggested that at some 15,000 ft. the isotherms are circular except for a tongue of warm air which projects in the direction towards which the storm is moving.

On the general circulation of the atmosphere, C. H. B. Priestly described how upper air data can be used to calculate the flow of heat and momentum over the whole of a parallel of latitude. The difference between the amounts flowing over two such circles of latitude was accounted for by absorption at the earth's surface in the area between them. Sir Geoffrey Taylor contributed a paper on convection currents in the atmosphere over a source of heat. He showed how laboratory experiments with a small source of heat like a Bunsen burner may be used to explain and describe the upward currents of air over a volcano or a forest fire. Instrumental techniques were described in several papers, which included an account of the upper air stations in the Canadian Arctic, the use of a balloon-borne instrument for measuring potential gradient, and the operation of meteorological balloons so controlled that they remain in given limits of height. E. G. Bowen described the artificial production of rain. The temperature of a cloud was first determined, and it was then seeded with 'dry ice' from an aircraft at frequent intervals. In most cases rain was produced when the temperature of the cloud was below the freezing point; but never when the temperature was above it.

In the Oceanography Section papers were presented in all aspects of the subject: geological, physical, chemical and biological. Among the geological studies an important feature was the abundance of new data from the survey of the U.S. Navy in the Pacific Ocean and of the Bikini Atoll. F. P. Shepard, of the Scripps Institution, reported the results of further exploration of deep-sea canyons. On the physical side it has become clear that one of the main objects of applied oceanography is to obtain a complete picture of the distribution of water of different physical and chemical properties and of the water movements. Since this is unlikely to be achieved by survey work alone, attention is being given to the fundamental processes by which radiation, wind, turbulent flow, and like factors affect the distribution and produce seasonal and other changes. Such new knowledge is imperatively needed, and its interest should attract to oceanography able mathematicians and physicists in the same way that marine biology has attracted zoologists. One such physicist, G. E. R. Deacon, was warmly appreciated for the lead he gave in a variety of problems when he described the Discovery Committee's work on surface boundaries in the South Pacific Ocean and also the researches of the Royal Naval Scientific Service on waves, microseisms and the electrical and magnetic effects of water movements and earth currents in the sea. The latter investigation revived earlier attempts by Faraday to apply this principle to the measurement of marine currents, and its success now places a new instrument in the hands of future observers. N. A. Mackintosh, the director of research of the Discovery Committee, communicated a paper on the distribution of whales in the South Pacific. Martin W. Johnson, of California, played recordings of sounds made by fish against the continual sound of the sea. The crackling sound made by the snapping shrimp, heard also through the hulls of yachts, resembled the sound of boring, or the noise of a busy factory. There were low grunts from sea-robins, while other fish made sounds like the chirping call of a bird, the mewing of a kitten, and the whirring sound of a propeller. Most spectacular were the sounds from porpoises, ranging from noises like the barking of dogs to the tuning-in whistles of a radio set. Long series of great hiccoughing noises were probably from humpback whales. Prof. C. M. Yonge, of Glasgow, gave a public lecture on the reef-building corals.

The Zoology Section covered a wide field; but the central theme was the consideration of the terrestrial, freshwater and marine faunas of the Pacific. Contacts with agriculture were made through economic entomology, and with oceanography by way of fish and fisheries and by joint discussions with these two related sections of the Congress. These talks led to a symposium on the protection of Nature in the Pacific and on the prospect of a world approach to international conservation.

There appeared to be two aspects of this latter problem. First there is the need for careful conservation in the Pacific area of the terrestrial and marine resources of raw materials and food for rapidly increasing human populations in the region. Fisheries have not yet been fully exploited, and interest centred around an American project to spend a million dollars on a survey of the marine resources and especially the tuna fisheries around Hawaii. The population of the Philippines depends almost wholly on rice and fish, and only an increased supply of the latter seems feasible as the immediate answer to the urgent problem of a rapidly rising human population.

The second aspect of conservation is the need to rescue and preserve agriculture from the ill-effects on native fauna and flora of introduced animals and plants. In the Hawaiian Islands, there are species of plants now confined to single areas and reduced to a few individuals. In New Zealand, also, innumerable problems have been created by the introduction of many species of plants and animals. Quite apart from the doubtful expedient of the original British settlers' of firing large areas of bush country as a means of clearance, widespread erosion has been caused by the destruction of mountain flora by deer, and the damage caused by opossums, goats, hedgehogs and rabbits is no less serious. No region in the world has suffered more from the effects of man's interference with Nature than the islands of the Pacific, including Australia and New Zealand. The Congress made detailed reference to these many problems and their remedies. The extermination in 1946 of the goats on the now uninhabited Three Kings Islands off the northern tip of New Zealand has resulted in the regeneration of the flora; the Islands were rapidly approaching the degree of bareness and aridity experienced in St. Helena more than a century ago. Valuable reports were presented by E. Mayr on the terrestrial faunas of the Pacific, including a survey of geological structure and geological history and their biological implications.

Distribution and utilization of marine Algæ received attention in the Botany Section. Distribution was considered to be more satisfactorily explained on the basis of continental drift than on the land-bridge hypothesis. Plant geography in the Pacific area was discussed, and attention was directed to O. H. Selling's publications on pollen studies of living Hawaiian plants and related genera elsewhere. Associated studies of the late Quaternary history of vegetation give striking indications of climatic waves in the recent history of these islands. C. Skottsberg discussed the flora of Hawaii and stressed the continental character rather than the insular, its strongest affinities being in the southerly Pacific area. Some results of recent research by the Swedish Deep Sea Expedition, and their bearing on the stability of the Pacific Ocean, were reported by H. Pettersson. H. J. Lam, of Leyden, outlined the progress of compilation of distribution maps of Pacific plant taxa. R. A. Silow, representing the Genetical Society of Great Britain, spoke on the problems of trans-Pacific migration involved in the origin of the New World cottons, and the suggestion of recent prehistoric influence from southern Asia in South America.

The section devoted to Soil Resources, Forestry and Agriculture took in a wide survey. The future of the Pacific countries depends largely on the right use of land resources. Methods of soil survey were compared, and differences were found to exist rather in nomenclature than in the actual nature of the categories. It is important to understand the genetic relationship of the soils mapped; discussions revealed a satisfactory overall agreement in aims and methods. Greater divergences appeared on the subject of land classification, where the objective is to integrate the physical, economic and other factors into a system which prescribes 'land-use capabilities'. Here the ascertainable facts are combined with personal judgment and have not the scientific accuracy of soil classifications, although examples of such land classification which had been proved accurate by experience were given. To many, 'land-use capability' is governed by erosion potential, which is a menace to be guarded against in all future land development.

In all this, forestry policy has an important place, and much time was devoted to problems affecting forestry in the Pacific area. Of exotic species tried in New Zealand, *Pinus radiata* was found to have been eminently satisfactory. Changes taking place in the general rural economy of the North Island were described by N. H. Taylor, of the Soil Bureau, Department of Scientific and Industrial Research, Wellington. This account was followed by an extensive tour in which the relation between soil, climate and the development of different systems of agricultural and forestry policy and production was clearly demonstrated. Large areas of North Island are covered by soils of fairly recent volcanic origin. The original forest was burnt off by early settlers to provide grazing lands. Lime and phosphate are the chief deficiencies where grass and clover are to be grown for intensive dairying. Despite such fertilizer treatment, scores of thousands of acres were of limited value for livestock farming owing to the intractable 'bush sickness'; but this has now been remedied by the application of cobalt salts. R. W. Phillips and C. P. Meekan opened discussions on dairy cattle improvement, and these led to lively comments. Such questions are receiving much less attention than they deserve in the Pacific countries. The outstanding developments of the Jersey for butter-fat production and of the Corriedale and other breeds for wool and fat-lamb production were, however, seen at first hand, as was also a Dutch Friesian herd of cattle with a butter-fat yield of well over four per cent.

Anthropology, Public Health and Nutrition, and Social Sciences were represented in three further sections of the Congress which often met in joint session. Sir Peter Buck, now director of the Bernice P. Bishop Museum at Honolulu, was a dominant figure; he was a medical graduate of Otago University at Dunedin, where most of his work has been done. His lectures and researches in anthropology, his book on the "Vikings of the Sunrise", and his part-Maori ancestry combined to make him the acclaimed, though modest, leader before popular audiences. V. W. T. McGusty, formerly director of medical services in Fiji, outlined the Colonial policy of administration in which primitive forms of society are protected and native medical officers are employed for the control of disease. Sir Peter Buck said this example is being followed by the United States in its trust territories in the Pacific. Similar training schools have been established at Guam which will provide native medical workers for the rest of Micronesia. E. Beaglehole, of Wellington, said that Colonial Powers are prone to believe that backward races require the same type of government as their own complex societies, whereas the islanders had a workable self-government before Europeans came, and would develop new procedures in their simple communities as their needs expanded. A. P. Elkin, of Sydney, said it has been proved that the aborigine in Australia can be led to an intelligent appreciation of the intruder's culture if his right to participate in citizenship is recognized. The report of the committee on blood groups of the Pacific area was given by H. L. Shapiro, of New York, and he also, along with

G. P. Murdoch, of Yale, outlined the anthropological studies in Micronesia. Papers on dental caries, tuberculosis and tropical diseases, together with reports on remedial measures, were contributed, and further research programmes were discussed. These sessions covered a wide and important field on medical and social problems, and represented a very live and vigorous section of the Congress. The present writer presided at a general Congress discussion on the "Social Implications of Science".

Parties of overseas delegates in groups of some twenty members were taken on conducted tours each of a week's duration through the North and South Islands. These tours were arranged to bring delegates south from Auckland to Christchurch with stops at interesting centres *en route*, and also after the termination of the Christchurch sessions. Apart from the scenic interest of these excursions by road, the delegates gained, by scientific intercourse and social fellowship, a lasting benefit comparable with, or even exceeding, that of the organised Congress itself.

In conclusion, it is a pleasant duty to acknowledge the help I have received from my fellow delegates from Britain in compiling this report, namely, Prof. G. W. Robinson, the leader; Sir Geoffrey Taylor; Prof. H. D. Kay; Prof. C. M. Yonge; Dr. G. E. R. Deacon and Dr. R. A. Silow, whose impressions, together with my own, I have endeavoured to record. These can, however, reflect only a small part of the whole work of the Congress.

PRE-STRESSED CONCRETE

In recent years there has been a growing interest among engineers in the use of pre-stressing for concrete structures, and on February 16 a conference was held at the Institution of Civil Engineers to review the present position of pre-stressed concrete. The conference was arranged under the auspices of the Institution and the Joint Committee on Materials and their Testing (a Committee representing some twenty-five technical and professional institutions and societies). The chair was taken, for the morning session, by Mr. R. H. H. Stanger, and, for the afternoon session, by Mr. W. K. Wallace.

A paper by Dr. F. G. Thomas, of the Building Research Station, had been prepared as a basis for discussion. The basic principle of pre-stressing, Dr. Thomas pointed out, consists in the imposition of preliminary internal stresses in a structure before the working loads are applied, in such a way as to lead to a more favourable state of stress when these loads come into action. The preliminary stresses induced in concrete are essentially pre-compressions, which may be uniform or non-uniform, with the primary object of avoiding cracking under the conditions of working load. In most practical cases the pre-stress is applied by stretched steel wires of high tensile strength.

A description of the early development of the technique was followed in the paper by a comprehensive survey of the basic features of pre-stressed concrete, including the materials used, the fundamental assumptions to be made in design and the various practical systems of pre-stressing. Dr. Thomas gave a brief account of the experimental investigations that have been made, and concluded with descriptions of constructional work executed in Great Britain and elsewhere. This section of the paper embraced references to bridges, tanks, reservoirs and pipes, buildings, and miscellaneous work such as tunnels, harbour construction, aeroplane runways and railway sleepers.

In introducing his paper, Dr. Thomas emphasized the need for high-quality materials to be used in pre-stressed concrete construction. Although a high strength of concrete is not always necessary, but often desirable, a high standard of quality control is essential. A high early strength of the concrete is required on economic grounds, and usually a rapid-hardening cement is adopted or suitable accelerators are incorporated in the concrete mix; curing with steam or electric heating is also of value in regard to rapidity of hardening.

For most of the design calculations, Dr. Thomas pointed out, no new theory is necessary. The classic theory of elasticity is applicable if approximate allowances are made for the effects of inelastic deformations due to creep (of steel and concrete) and to shrinkage of the concrete. There are two main systems of pre-stressing: the pre-tensioning system, in which the wires are stretched before the concrete has set; and the post-tensioning system, in which the wires are stretched after the concrete has hardened and obtained considerable strength. Whatever basic system of pre-stressing is adopted, there are many variations in the actual detailed arrangements. A study of the relative merits of the main processes has led Dr. Thomas to the conclusion that there is no general technical justification for one rather than another; the method to be chosen appears to depend upon technical and economic considerations relating to the particular circumstances of each design.

Referring to constructional work already completed, Dr. Thomas observed that the main advantages of pre-stressing have been obtained in beams and fluid-retaining structures. In the case of beams, the greatest advantages are reached where the effects of reduced sections and light weight are particularly important, that is, in bridges of larger span. In the case of fluid-retaining structures, where cracking must be avoided and where difficulty has been experienced in obtaining satisfactory joints in ordinary reinforced concrete, it seems certain that in the future a greater proportion of these structures will be made of pre-stressed concrete.

The possibility of using pre-stressing for roads or runways is of interest, particularly in view of the difficulty experienced in the past in obtaining good joints. In the Orly Airport runway, Freyssinet has experimented in this direction, and it may well be that pre-stressing will solve another difficult civil-engineering problem.

In the discussion which followed the presentation of the introductory paper, several speakers emphasized the desirability of using high-grade materials. Mr. J. W. H. King (Queen Mary College, London) pointed out that metallurgical study shows that the hard-drawn wire commonly used for pre-stressing possesses certain properties as a result of the drawing process in manufacture (for example, creep under sustained load or deformation) which are detrimental to the efficiency of the wire as a pre-stressing agent, subject to high tensile stress for the whole life of the structure. Prof. R. H. Evans (University of Leeds) agreed with Dr. Thomas that with 0·2-in. diameter wire the margin of safety against wire slip, in systems dependent on the bond between concrete and steel, is often not sufficient. Tests at the University of Leeds have shown that, for the transfer of the pre-stressing load from the steel to concrete by surface interaction alone, a length of wire of 80–250 diameters is necessary. Triple-stranded wires have been found to have better bond characteristics than single round wires. Mr. U. Bjuggren (Stockholm) remarked that in Sweden small-diameter (0·08-in.) wires are used in pre-tensioning systems; up to 140 wires have been used in a relatively small cross-section, and satisfactory bond has been obtained.

In regard to the concrete quality, Dr. A. R. Collins (Cement and Concrete Association) spoke of the simplicity of the arrangement of steel in pre-stressed concrete, contrasting this with the conglomeration of reinforcement in ordinary reinforced concrete. The simplicity is coupled with a greatly reduced amount of steel and allows the use of a concrete of relatively low workability and high durability. Concrete of high strength is not difficult to obtain if adequate control is exercised in the measurement and proportioning of the materials, and if the water content is limited to the minimum necessary for proper compaction of the concrete.

Mr. R. S. V. Barber (Dow-Mac (Products), Ltd.) and Mr. J. Ludlow (Metropolitan-Vickers Electrical Co., Ltd.) described work on electric heating as a method of accelerating the hardening of concrete, pointing out that electric heating can be arranged with the electric current passing through the concrete or alternatively through the reinforcing wires. The former has been used as a conductor, particularly in the U.S.S.R., to avoid frost action during the early hardening of the concrete, but a high current-density may affect the proper hydration of the cement. Mr. Barber and Mr. Ludlow said that they have therefore used the alternative method, namely, of heating the embedded wires, in the production of concrete railway-sleepers. This method has the advantages that the electrical resistance of the steel is constant, stable and small. The arrangement of straight wires in the pre-tensioning system is ideal for this treatment, which has resulted in a reduction in the production cycle from five to one day or even less.

On the fundamental approach to the design of pre-stressed concrete members there was some divergence of opinion. Prof. A. L. L. Baker (University of London) presented an analytical method for the determination of the ultimate strength of a pre-stressed concrete beam, and Prof. A. D. Ross (University of London) discussed the accurate assessment of losses of pre-stress due to inelastic deformation of the concrete. Other speakers were in favour of simple approximations for these losses; and Mr. Bjuggren (Stockholm) relied for his designs on empirical rules based on hundreds of tests.

The application of pre-stressed concrete to various structural systems was discussed by several speakers. Major A. J. Harris (Société Technique pour l'Utilisation de la Précontrainte, Paris), representing M. E. Freyssinet, showed how the difficulties of obtaining structurally continuous systems have been overcome in France. In statically indeterminate systems, pre-stressing tends to modify the supporting reactions for beams, involving an elaboration of the design calculations, and it also introduces practical difficulties. M. Freyssinet has devised a system of beams of variable cross-section, pre-stressed by straight cables, which has largely obviated the difficulties. In an alternative solution, the reactions are adjusted in practice to the values assumed in design, by introducing special small flat jacks. Major Harris also described the construction of bridges from pre-fabricated units. Elements 6 ft. long, cast in a factory, are later assembled to form a 240-ft. span bridge, the elements being held together by pre-stressing cables.

Mr. N. W. Swinnerton (British Railways) described the development of pre-stressed concrete railway-sleepers in Great Britain, involving laboratory tests and trials in high-speed track, leading to two designs which show promise. Mr. J. S. Campbell and Dr. P. W. Abeles (British Railways) spoke of successful bridge construction already completed in Great Britain and of further work soon to be started. In this latter connexion, Dr. Abeles discussed designs in which pre-stressed units would be combined with *in situ* concrete without preliminary stress, and gave details of tests showing that such composite construction is practicable and amenable to accurate stress analysis.

Mr. L. W. Elliott put forward the architect's point of view on pre-stressed concrete. The three essential considerations are the æsthetic, the functional and the economic aspects. The practical examples have shown that æsthetic and functional requirements can be well satisfied, and it appears that this type of construction is also economical. Mr. D. H. May (Stressed Concrete Design, Ltd.) discussed the economical aspect further, and gave evidence of cases in which pre-stressed concrete has been chosen, in direct competition with steel and reinforced concrete, for several structures in Europe and in America.

The proceedings of the conference are to be published later this year.

NEW FELLOWS OF THE ROYAL SOCIETY

AT the meeting of the Royal Society on March 17, the following were elected to fellowship:

Prof. J. F. Allen, professor of natural philosophy, University of St. Andrews, distinguished for his work in low-temperature physics, especially for his discovery of new phenomena shown by liquid helium.

R. W. Bailey, head of the Mechanical and Metallurgical Research Department at Metropolitan-Vickers, Manchester, distinguished for contributions on the behaviour of metals at high temperatures and for advances in design of turbines.

Dr. F. C. Bawden, head of the Plant Pathology Department at Rothamsted Experimental Station, Harpenden, distinguished for his work on plant viruses and virus diseases, and for important contributions to the study of virus serology.

Prof. F. W. Rogers Brambell, Lloyd Roberts professor of zoology, University College of North Wales, Bangor, distinguished for his experimental studies of processes of reproduction in mammals and of the factors concerned in antenatal mortality.

Prof. K. E. Bullen, professor of applied mathematics in the University of Sydney, distinguished for work in geophysics, particularly in relation to earthquakes and the distribution of density within the earth.

Dr. E. B. Chain, university demonstrator in chemical pathology, University of Oxford, distinguished for his work on enzymes of snake-venom and bacteria, and especially for his researches on penicillin and other antibiotics.

Dr. U. R. Evans, reader in metallic corrosion, University of Cambridge, distinguished for his researches on metallic corrosion.

Prof. E. D. Hughes, professor of chemistry, University College, London, distinguished for his researches in the mechanism of the reactions of carbon compounds.

Prof. W. Q. Kennedy, professor of geology, University of Leeds, distinguished for his contributions to tectonic geology and petrogenesis.

Prof. W. B. R. King, Woodwardian professor of geology, University of Cambridge, distinguished for his researches on the Lower Palæozoic rocks and on Pleistocene deposits.

Sir Ben Lockspeiser, chief scientist, Ministry of Supply, distinguished for his contributions to the development of modern aircraft.

Dr. J. M. McNeill, naval architect, John Brown and Co., Ltd., Clydebank, distinguished for his contributions to naval architecture.

Dr. H. R. Marston, chief of the Division of Biochemistry and General Nutrition, Commonwealth Council for Scientific and Industrial Research (University of Adelaide, South Australia), distinguished for his researches on nutrition and wool-growth in merino sheep and on trace element-deficiency diseases in ruminants.

Prof. K. Mather, professor of genetics, University of Birmingham, distinguished for his contributions to genetics and particularly for his studies of polygenic inheritance.

Prof. P. B. Medawar, Mason professor of zoology and comparative anatomy, University of Birmingham, distinguished for his studies of growth processes and the phenomena associated with tissue transplantation

Dr. W. T. J. Morgan, research worker, Lister Institute of Preventive Medicine and reader in biochemistry in the University of London, distinguished for his contributions to the chemistry of immunology and blood groups.

N. W. Pirie, head of the Biochemical Department, Rothamsted Experimental Station, Harpenden, distinguished for his researches on the chemical and physical properties of plant viruses.

Prof. C. F. Powell, Melville Wills professor of physics, University of Bristol, distinguished for his contributions to experimental physics, especially for his work on the properties of mesons.

Dr. D. A. Scott, research member, Connaught Laboratories, University of Toronto, distinguished for his contributions to the chemistry of insulin, heparin and carbonic anhydrase.

Prof. Wilson Smith, professor of bacteriology, University College Hospital Medical School, London, distinguished for his researches on the virus of influenza and on the pathology of staphylococcal infections.

Dr. G. B. B. M. Sutherland, reader in spectroscopy, Department of Colloid Science, University of Cambridge, distinguished for his experimental researches on infra-red and Raman spectroscopy, especially of hydrocarbons.

Prof. O. G. Sutton, professor of mathematics and physics, Military College of Science, Shrivenham, distinguished for his researches in atmospheric turbulence and evaporation.

Prof. Meirion Thomas, professor of botany at King's College, Newcastle-upon-Tyne, distinguished for his researches in plant physiology, and particularly for his work on the breakdown of sugar in the plant.

Prof. J. M. Whittaker, professor of mathematics, University of Liverpool, distinguished for his researches in the theory of integral functions.

Prof. F. G. Young, professor of biochemistry, University College, London, distinguished for his studies of the role of the hormones of the anterior lobe of the pituitary gland in carbohydrate metabolism.

NEWS and VIEWS

King's College, London: Prof. W. T. Gordon

PROF. W. T. Gordon retires at the end of the present session from the chair of geology, King's College, London. He joined the staff of the College as lecturer in charge of the then quite small Department of Geology in 1914. In 1921 he became professor of geology, a post held in the earlier days of the College by Charles Lyell, John Phillips, D. T. Ansted, James Tennant and Martin Duncan. It fell to Gordon to organise the expansion of the Department and its work which followed the First World War, and he also served as administrative head of the Department of Geography conducted jointly with the London School of Economics. Throughout his long years of service, Prof. Gordon has been a well-known and well-loved figure in his College and his University, taking a large part in the life and work of both. At the same time he has continued to prosecute his researches into the Scottish Lower Carboniferous flora, begun as a young man in Edinburgh. Not the least of his great services to his College arose from his abiding interest in mineralogy: the Department possesses by virtue of his efforts an unusually fine collection of well-crystallized minerals, and his own collection of gem stones has become justly famous to a long succession of students.

Dr. J. H. Taylor

DR. J. H. TAYLOR, who succeeds Prof. Gordon as professor of geology at King's College, London, in September, was educated at Clifton College, Bristol, and was an undergraduate at King's College. As such, he distinguished himself in every field, in scholarship, athletics and general service to the College. He obtained first-class honours in geology at the Final Examinations of the University of London, and, as the most distinguished man of his year in science at King's College, he was awarded the Jelf Medal, the most prized distinction to which a student can aspire. After a year's service on the staff of the Geological Department at King's College, he was elected to a Henry Fellowship at Harvard University, and while there he obtained the degree of A.M. Returning to Britain to join the Geological Survey of Great Britain, he continued his petrological researches into the rocks of the East Midlands, and particularly the sedimentary iron ores and associated rocks of Northamptonshire and Leicestershire. He was, consequently, selected as a member of the party asked to study and report upon the mining methods in Germany used to work the Cretaceous iron ores of the Salzgitter-Ilsede region, and the Dogger ores of Bavaria, Württemberg and Baden. While a member of the Geological Survey, Dr. Taylor continued lecturing work at the Working Men's College, Crowndale Road, London, and has been a member of Council of that College for many years. It will be clear from these varied activities that Dr. Taylor is a man of personality and drive. He has had a wide experience in geological work in the class-room and in the field in Britain, America and on the Continent, and will bring a highly trained, versatile and well-balanced mind to the problems of university education in geology.

Engineering at the University of Leeds: Prof. D. G. Christopherson, O.B.E.

DR. D. G. CHRISTOPHERSON, whose appointment as professor of mechanical engineering at the University of Leeds, in succession to the late Prof. W. T. David, has been announced, was educated at Sherborne School and University College, Oxford, where he took first-class honours in engineering science in 1937. He held a Henry Fellowship at Harvard University during 1938–39, and was for several years a member of Sir Richard Southwell's research team developing 'relaxation methods'. He was part author of the first paper in which the application of these methods to partial differential equations was presented, and his thesis for the Ph.D. degree in 1941 dealt entirely with this important branch of the work. During the period 1941–45, he was a member of the scientific staff of the Research and Experiments Department, Ministry of Home Security, and was made an O.B.E. in 1945. Dr. Christopherson was appointed a University demonstrator in the Department of Engineering, Cambridge, in April 1945, and was elected a Fellow of Magdalene College. In 1946 he was promoted to lecturer and in 1947 he became bursar of Magdalene. Though Christopherson has contributed papers on vibrations and structural problems, his interests lie mainly in the region of applied mechanics, and particularly in the theory of lubrication.

Holweck Prize and Medal: Prof. L. F. Bates

DR. L. F. BATES, Lancashire-Spencer professor of physics in the University of Nottingham, has been awarded the Holweck Prize and Medal by the Société Française de Physique. The Holweck Prize was founded by the Physical Society as a memorial to Fernand Holweck, director of the Curie Laboratory of the Radium Institute in Paris, and to other French physicists who were killed by the Germans during the occupation. The Société Française de Physique founded the Holweck Medal in bronze for presentation to the prizewinner. The award is made annually, alternately to a French and to a British physicist, for distinguished work in experimental physics. Prof. Bates is a leading authority on experimental magnetism. His book "Modern Magnetism", which appeared in 1939, has achieved an international reputation, and a second revised and enlarged edition appeared last year. His original work in an experimental field known for its difficulty is distinguished by a technique which he has built up since 1924 entirely by independent effort. In particular, his work on the heat liberated in step-by-step magnetism in the hysteresis cycle has advanced knowledge in a field where progress has long been retarded by the experimental difficulties. His work on the changes of specific heat at the ferromagnetic Curie point and his investigations of other properties of ferromagnetic substances are outstanding. His investigations in magnetism constitute a solid body of successful achievement which commands attention and admiration both at home and abroad. Magnetism is a subject in which there is now much interest in France, as instanced by the work of Néel and his school, and Prof. Bates will be warmly welcomed when he delivers his lecture in Paris in the early summer.

University of Birmingham and the Midland Region

AMONG other topics dealt with by the Vice-Chancellor of the University of Birmingham (Sir Raymond Priestley) in his report to the Court of Governors is that of the cordial relations between the University and the Midland region. During the period 1935–47 the University received £1,450,000 in benefactions, excluding further promises under seven-year covenants of about £700,000, a fine record for its friends and supporters; and in this respect it surpasses all universities except Oxford. Local government grants, too, have substantially increased, facts which are regarded by the Vice-Chancellor as a recognition of success and a token of confidence. A significant development has been the establishment of the Midland Advisory Council on Industrial Productivity, "an attempt to gear the new development in Engineering Production (made possible by the generous benefaction of Messrs. Joseph Lucas, Ltd.) to the regional productive drive". The Lucas chair in the principles of engineering production, of which Prof. T. U. Matthew is the first occupant, has as its object postgraduate teaching and research on engineering production and the principles of industrial management. This Advisory Council is intended to promote closer liaison between Midland industries and the University of Birmingham in order to improve standards of productivity. A further expression of the support of industry is the generous provision by Tube Investments, Ltd., of £1,500 per annum for seven years for the establishment of a research fellowship in engineering production. The first holder of this fellowship is Mr. Mansergh Shaw, senior lecturer in engineering in the University of Melbourne. To assist Prof. Matthew in developing the postgraduate courses, Mr. P. B. R. Gibson has been appointed as lecturer, and lectures in engineering economics for final-year mechanical and electrical engineering students have been arranged as introductory to the postgraduate courses. It is expected that postgraduate students will be, in the main, sent by industrial firms; they will be expected to have had considerable industrial experience and to possess the attributes essential for success in management.

Philosophical Society of the Sudan

A NATION is judged not only by its resources and productivity but also by its standard of scholarship and culture; and an indication of this may be estimated by its number and quality of learned societies. In company with the present-day awakening throughout Africa, the Sudan is, and has been, making great progress in the field of economic development and towards a larger measure of self-government. It is pleasant to report that learning is keeping pace with this development, and that the Philosophical Society of the Sudan, which was founded on February 2, 1946, is flourishing and setting a high standard. The *Proceedings* for 1946–47 record the activities of this Society for the first year of its existence. At the inaugural meeting seventy-five founder members were enrolled, and the officers and committee were elected. Soon after, at the first ordinary meeting, the president, Mr. A. J. Arkell, gave his address. After discoursing on archæological discoveries in the district, he went on to stress the wide possibilities of local research in the various fields of archæology, geology and geography for piecing together the history of the Sudan, and also the need for research on modern aspects of Sudanese life, such as local industries and crafts, place-names, languages, customs, etc. Finally, there was the necessity for an adequate museum and library to consolidate and display the results of such research.

This presidential address seems to have been taken up by the members of the Society, for, during the year, papers were presented dealing specifically with the Sudan on the following subjects: archæological finds in local caves; manuscripts relating to the early Muslim period; distribution of types of soil and discoveries of fossils; relation between soils and local vegetation; Turkish administration during 1823–37; agricultural research; history during 800 B.C.—A.D. 350; and archæological finds (this last being another address by the president). Other papers which were of rather more general interest included such topics as transport, light reading in the Middle Ages, welfare and development, examinations, rates of evolution, and forestry. The Society is to be congratulated on a successful year and on its increase of membership to more than a hundred. The officers for 1948–49 are: *President*, Dr. J. Smith; *Vice-President*, G. W. Ogden; *Honorary Secretary*, A. W. Ireland; *Assistant Honorary Secretary*, L. S. Cobley; *Honorary Treasurer*, G. C. Wood. The address is the Secretary's Office, c/o General Post Office, Khartoum.

Limiting Factors in World Development

In his address, "Limiting Factors in World Development, or What is Possible", to the Associated Scientific and Technical Societies of South Africa at Johannesburg on August 11, 1948, Sir Harold Hartley suggested that a primary cause of our present troubles is the failure to realize that in the twentieth century, with the exploitation of the virgin lands, the slowing down of the growth of population and the disappearance of 'easy money', a new technique is required to give a dynamic impulse to international trade and stimulate both production and purchasing power. The future depends on increasing both production and purchasing power, and Sir Harold then examined more particularly the limiting factors in agricultural production. Of these, water comes first, and he stressed the importance of irrigation, draining and soil conservation. Climate comes next, and here we have the problem how far science can overcome the handicap of temperature extremes by improved living conditions, diet and clothing. Soil presents a very intricate and difficult scientific problem; but great advances are being made, although we are only now realizing the delicate balance in the top few inches of soil on which fertility depends. Next comes man-power and human skill, involving questions of education, physique and incentives if production is to be improved. Diseases and pests have been a major limiting factor; but here we have immediate reason for optimism in recent discoveries and developments both for protecting the individual and for the eradication of carriers of disease and destruction of pests themselves.

Transport is another determining factor by making possible the exchange of commodities and the movement of individuals, and Sir Harold stressed the value of air transport in opening up undeveloped regions. This factor is intimately linked with the economic factor of energy and power and the corollaries of equipment and capital, and in this connexion he said there must be a growing emphasis on the processing of farm and forest products; this is a great new field for the agriculturist and the chemical engineer. Finally, an orderly solution of the problems of production in any area depends on a survey of its natural resources, human geography, economic structure and capacity for production and consumption. The technique of making such surveys is in its infancy, and Sir Harold stressed the contribution of the aeroplane and of wireless. Moreover, the value of such national surveys would be enhanced by some clearing house through which the results could be made available for all countries. In human engineering, however, man is the limiting factor, and we are fighting once more for the freedom and ethical standards of Western civilization. Nevertheless, men with vision and imagination, with the power to foresee what modern methods can achieve, with confidence in the future and with human interest in the backward peoples and determination to improve their lot, will be the pathfinders in the quest of plenty.

National Research Council (Canada): Review of 1948

The "National Research Council Review, 1948" (N.R.C. No. 1713. Pp. 216. Ottawa: King's Printer, 1948. 75 cents) describes the work of the Council during the year ended December 31, 1947, and gives more detailed information regarding the work of the laboratories than is contained in the annual report, the last (thirty-first) of which covered the year ended March 31, 1948 (see *Nature*, November 6, p. 748). Besides the more specific accounts of work in progress, the Review includes a full list of scientific staff, arranged by Divisions, now totalling 2,682 persons, with details of the representation of the National Research Council on outside committees. In addition to statistics of scholarships and fellowships awarded in 1947–48 and their distribution, there is an analysis of those awarded during 1917–48. Reports from the various Associate Committees list the members of those Committees, while the value of the reports from the Divisions of Atomic Energy Research, Applied Biology, Chemistry, Applied Chemistry, Mechanical Engineering, and Radio and Electrical Engineering is enhanced by the inclusion of lists of publications of the Divisions during the year. The Review is thus a most useful annual reference work on the work of the Council. Reference has already been made (*loc. cit.*) to features of the work of the Council during the year. It can only be added here that besides giving a clear picture of the organisation and activities of the Atomic Energy Research Division, the Review refers to a development unnoticed in the annual report—the establishment of a new company, Canadian Patents and Developments, Ltd., with a board of directors of representatives from industry, the universities and the National Research Council. The primary purpose of this Company is to make available to industry through licensing arrangements the inventions, new processes and improvements in processes, developed by the scientific workers of the Council. It is anticipated that the Company will eventually have charge of all Government-owned patents which can be made available to industry, including some 1,300 enemy patents now held by the Custodian of Enemy Property. The Company is also intended to provide a channel for the flow to industry of new developments by scientific workers in the universities.

Ancient Pottery of the Near East

POTTERY sherds, when they occur, are some of the most useful 'fossils' the prehistorian can have to deal with. When they are found with an industry, one can be almost certain that they are contemporary. It follows, then, that a known ware imported from some distant region and found associated with an unknown industry will date that industry with reasonable accuracy as being contemporary with the culture which manufactured the particular ware in question. This is not so true in the case of beads. It is a fact, of course, that when the association is real and there has been no subsequent chance introduction, the industry with which the bead of known date is found must be either contemporary with it or later in date. But beads have a long survival value; necklaces made of Egyptian beads were popular in late Victorian times, thousands of years after they were made. Prehistoric housewives, however, smashed crockery as freely as their descendants, and the survival value of a pottery vessel in use is limited. Pottery, then, is particularly useful for correlating in time various cultural levels from different regions. We can therefore be grateful to Marian Welker, who in a paper entitled "The Painted Pottery of the Near East in the Second Millenium B.C. and its Chronological Background", has brought together in convenient form a wealth of detail of the pottery in the Near East at this period (*Trans. Amer. Phil. Soc.*, N.S., **38**, part 2; September 1948). The paper is arranged by sites and areas, considering especially a number of Syrian localities. The author considers that Mesopotamian influence on the development of the wares in these sites is sporadic and that we shall have to look rather to an Iranian cradle for their origin. Chronological tables and some pages of illustrations are included, and the resulting volume will certainly prove of great use to students. There are also a catalogue of forms and several pages of references.

Society of Public Analysts and Other Analytical Chemists

THE seventy-fifth annual general meeting of the Society was held on March 9 in the meeting room of the Royal Society, Burlington House, London, W.1, with the retiring president, Mr. Lewis Eynon, in the chair. In his address, Mr. Eynon began by remarking on the Society's membership of 1,500, a doubling of the figure of ten years ago; he announced that, in alternate years in which no change of president occurs, the lecture which is delivered at the annual general meeting will in future be known as the Bernard Dyer Memorial Lecture, in honour of the late Dr. Bernard Dyer. The main theme of Mr. Eynon's address was the fundamental importance of analysis to the progress of chemistry and the necessity for giving a prominent place to analysis in the training of the student of chemistry. He said that although two former presidents of the Society had both deplored the inadequacy of training in analytical chemistry, little advance has been made in the status of analysis as a subject of instruction in the universities and technical colleges of Great Britain; indeed, the position has if anything become worse owing to the increasing claims of other branches of the science on a student's time. The great utilitarian value of training in analysis is too obvious and manifold when one considers its application to industry, medicine, water supply and Government inspection. The most important practicable step is for the establishment of chairs of analytical chemistry in universities and colleges and for a longer period of training for the student. With the present unsatisfactory conditions of training there is a serious danger that within the next twenty years the analyst himself will be "weighed in the balance and found wanting".

The following officers and members of Council were elected for the ensuing year: *President*, George Taylor; *Past Presidents serving on the Council*, F. W. F. Arnaud, Lewis Eynon, E. B. Hughes, G. Roche Lynch, S. E. Melling, G. W. Monier-Williams; *Vice-Presidents*, C. A. Adams, H. E. Cox, J. R. Nicholls, J. G. Sherratt (chairman, North of England Section), J. Sword (chairman, Scottish Section); *Honorary Treasurer*, J. H. Hamence; *Honorary Secretary*, K. A. Williams; *Other Members of Council*, N. L. Allport, R. C. Chirnside, J. F. Clark, D. C. Garratt, J. G. A. Griffiths, E. T. Illing, J. King, J. E. Page, C. J. Regan, F. A. Robinson, N. Strafford, A. M. Ward, A. Lees (honorary secretary, North of England Section), R. S. Watson (honorary secretary, Scottish Section).

New Grassland Research Station at Hurley, Berks

A NEW Grassland Research Station for Great Britain is being established by the Minister of Agriculture and the Secretary of State for Scotland in co-operation with the Agricultural Research Council. The new Station will occupy an area of 500 acres at Hurley, Berkshire, adjoining the new Berkshire Farm Institute. Its work will be the investigation of problems relating to the sward and its production and maintenance under different conditions, but mainly under those of medium and low rainfall. The existing Grassland Improvement Station at Drayton, Stratford-on-Avon, will be transferred to and amalgamated with the new Station. The work at Hurley will be carried out in close co-operation with that of the Welsh Plant Breeding Station at Aberystwyth, the Scottish Society for Research in Plant Breeding and other research institutions, and it will be under the scientific supervision of the Agricultural Research Council. The Station will be controlled by a Governing Body which will be constituted as a company limited by guarantee and without share capital, grant-aid being given by the Ministry of Agriculture. The thirteen members who have been appointed to the Governing Body, and of which Prof. H. G. Sanders is chairman, provide a balanced representation of scientific knowledge and practical farming experience.

Liquid Helium-3

IN the *Physical Review* of January 15, p. 303, S. G. Sydoriak, E. R. Grilly and E. F. Hamel report that on October 13, 1948, they succeeded in condensing pure helium-3. This is especially interesting, since several physicists, F. London, Tisza, and others, have expressed doubts that helium-3 would liquefy. Twenty c.c. (measured at S.T.P.) of helium-3 were used, and condensation took place at the bottom of a 1·2-mm. bore stainless steel capillary immersed at a depth of 5–10 mm. in the liquid helium well. Condensation was assumed to be taking place when the equilibrium pressure in the capillary was independent of the volume of helium which remained in the mercury manometer connected to the room-temperature end of the capillary. From the data obtained, $3{\cdot}3_4$° K. was chosen as the critical temperature of helium-3. The vapour pressure measurements showed that at 1·2° K. the vapour pressure of helium-3 was thirty-five times that of helium-4; helium-3 was suitable for thermometry at low temperatures down to 0·5° K. and perhaps lower; the normal boiling point of helium-3 was 3·2° K., and by extrapolation to the critical temperature the critical pressure was 875 mm. of mercury. A value of 0·041 gm./c.c. for the critical density was deduced.

Birds in London

In April 1947 the Minister of Works appointed a Committee on Bird Sanctuaries in the Royal Parks (England and Wales). For its general objectives the Committee decided to: (1) make suggestions for increasing the resident population of birds, their number and variety; (2) make suggestions for attracting migratory birds and for inducing unusual visitors to stay longer; (3) select competent persons as observers and reporters.

The Committee has now reported, and the results of its deliberations have been set out in a pamphlet, "Birds in London" (H.M. Stationery Office. *9d.*). The first duty was the appointment and guidance of competent observers, and it is their statements which provide most of the material in the pamphlet. They show how successful has been the policy of developing the London bird sanctuaries, which were originally set up so long ago as 1923.

Young Children

To mark the year of its silver jubilee, the Nursery School Association of Great Britain has begun the publication of a new quarterly journal. This follows the formation of the World Council of Early Childhood Education after an international meeting in Prague in August 1948, and the new journal is intended to act as a link between all who are interested in the education of young children in any part of the world. Volume I of *Young Children* contains articles on the use of water play in the nursery, the stages of education which follow the nursery school and the links between home and school. The new journal has been produced unpretensively and should strengthen a side of education which has been much neglected by existing journals. It is doubtful, however, if the new journal will survive unless the price is reduced.

Hundredth Meeting of the Genetical Society

The Genetical Society of Great Britain, founded in 1919 by William Bateson, will hold its hundredth meeting during June 30–July 1, in Cambridge. To mark the occasion guest speakers will review the early days of genetics, and there will also be comprehensive demonstrations of genetical work now in progress in Great Britain. Genetical societies abroad have been informed of this meeting, to which all geneticists are cordially invited. Details may be obtained from the secretaries, G. Pontecorvo, Department of Genetics, University, Glasgow, W.2, or H. G. Callan, Institute of Animal Genetics, University, Edinburgh 9.

The Night Sky in April

Full moon occurs on April 13d. 04h. 08m., u.t., and new moon on April 28d. 08h. 02m. The following conjunctions with the moon take place: April 9d. 13h., Saturn 3° S.; April 20d. 03h., Jupiter 5° N.; April 29d. 21h., Mercury 0·7° S. Mercury is in superior conjunction on April 13 and is not favourably placed for observation until later in the month; the planet sets 1h. 45m. after the sun on April 30, and can be seen in the western sky. Venus, in superior conjunction on April 16, is too close to the sun for favourable observation throughout the month. Mars rises about the same time as the sun during April, and cannot be observed. Jupiter is a morning star, rising at 3h. 20m., 2h. 30m. and 1h. 35m., at the beginning, middle and end of the month, respectively, and can be seen low down for a few hours before sunrise. Saturn sets in the early morning hours and is visible throughout the greater part of the night. Occultations of stars brighter than magnitude 6 are as follows: April 1d. 19h. 46 3m., 45 Arie. (*D*); April 7d. 00h. 31·4m., *c* Gemi. (*D*); April 11d. 20h. 56·3m., η Virg. (*D*). *D* refers to disappearance, and the latitude of Greenwich is assumed. The Lyrid meteor shower is active about April 18–24. A total eclipse of the moon, visible at Greenwich, takes place on April 13, the circumstances of which are given as follows: moon enters penumbra, 01h. 31·6m.; enters umbra, 02h. 27·7m.; total eclipse begins, 03h. 28·0m.; middle of eclipse, 04h. 10·9m.; total eclipse ends, 04h. 53·8m.; moon leaves umbra, 05h. 54·1m.; leaves penumbra, 06h. 50·3m. A partial eclipse of the sun, visible at Greenwich, occurs on April 28, its magnitude being 0·41 at Greenwich, where it begins at 6h. 21m., reaches its greatest phase at 7h. 15m., and ends at 8h. 14m.

Announcements

On the joint recommendation of the presidents of the Royal Society and the Institution of Civil Engineers, the Council of the Institution of Civil Engineers has awarded the James Alfred Ewing Medal for 1948 to Sir Edward Appleton. The medal is awarded annually, and was founded in 1936 in memory of Sir Alfred Ewing. This award has come appropriately when Sir Edward has just taken up his appointment as vice-chancellor of the University of Edinburgh, a position which Sir Alfred Ewing occupied with such distinction.

Dr. R. P. Linstead, director of the Chemical Research Laboratory, Teddington, since 1945, has accepted the invitation of the University of London to succeed Sir Ian Heilbron as professor of organic chemistry and director of the Organic Chemistry Laboratories at the Imperial College of Science and Technology as from April 1, or as soon afterwards as can be arranged.

M. Gaston Dupouy has been elected *correspondant* for the Section of General Physics of the Paris Academy of Sciences in succession to Prof. W. J. de Haas, who has been elected a foreign associate.

A division of the Royal Aeronautical Society has recently been formed in South Africa on the same lines as those formed in Australia and New Zealand in October 1948. Associate fellows will still be elected by the parent body of the Society in London; but otherwise these Divisions of the Commonwealth will possess a fully self-governing status and will be free to develop along their own national lines.

The Royal Photographic Society will be holding its annual exhibition at 16 Princes Gate, London, S.W.7, in two parts: part 1 (pictorial and colour), September 9–October 2; part 2 (scientific, Nature, medical, record, press, commercial, industrial, technical and radiographic), October 8–26. Admission will be free. Entries must be received by July 23, and entry forms may be obtained from the Secretary at the above address.

A New Analgesic Drug Analogous to *iso*Amidone

IN the course of our search for new analgesics free from undesirable side-effects, 6-piperidino-4 : 4-diphenyl-5-methyl-3-hexanone (III) (the piperidyl analogue of *iso*amidone) has been synthesized by the following route :

$$Ph_2CH.CN + ClCHMe.CH_2NC_5H_{10} \rightarrow$$
$$\text{(I)}$$
$$Ph_2C(CN).CHMe.CH_2NC_5H_{10} \rightarrow$$
$$\text{(II) (HCl, m.p. 225–226°)}$$
$$Ph_2C(CEt : NH).CHMe.CH_2NC_5H_{10} \rightarrow$$
$$\text{(2HCl, m.p. 193°)}$$
$$Ph_2C(COEt).CHMe.CH_2NC_5H_{10}$$
$$\text{(III) (HCl, m.p. 197–198°)}$$
$$\text{(HBr, m.p. 208–209°)}$$

In the combined synthesis of amidone and *iso*amidone it has been shown that at least two isomeric nitriles are formed by the condensation of diphenylacetonitrile (I) and 1 (or 2)-chloro-2-(or 1)-dimethylaminopropane, owing to ring formation in the latter[1], and in view of the isolation of a third isomer of amidone[2] other chemical mechanisms may also operate. As the synthesis shown in the above scheme does not, therefore, establish the structure of the product, this was elucidated by the process of exhaustive methylation on the penultimate nitrile (II) on lines similar to those described by Schultz, Robb and Sprague[3].

Degradation of the nitrile (II) gave *N*-methylpiperidine (picrate, m.p. 222° [4]) and 2 : 2-diphenyl-3-methylbutenenitrile, m.p. 64–65°, apparently identical with that obtained by the American workers[3]. On hydrogenation it gave 2 : 2-diphenyl-3-methyl-*n*-butylamine, of which the phenyl urea derivative, m.p. 204–205°, was identical with a specimen synthesized by an independent method. Work is now proceeding with the view of isolating any other isomer of (III) that may be formed.

The piperidyl analogue of *iso*amidone has proved of considerable pharmacological interest, since it shows the smallest degree of undesirable side-actions of any of the active analgesic drugs we have yet studied. The methods used for the assessment of toxicity, analgesic and respiratory depressant activities have been described[5,6], and the results obtained with this compound are shown in the accompanying table, together with the figures previously reported for amidone and *iso*amidone. In all cases morphine has been used as the standard for the measurement of analgesic and respiratory depressant actions.

'Piperidyl *iso*amidone' (III) shows the same effects in acute animal toxicity experiments as amidone or *iso*amidone, death in all cases resulting from acute cardiac failure. All these compounds differ from morphine in this respect, since they are many times more toxic upon rapid intravenous injection than is morphine, although the toxicities in sub-acute experiments are very much more similar to that of morphine. All the compounds referred to, with the exception of morphine, are toxic to the isolated rabbit heart (Langendorff's preparation) at concentrations stronger than 1 part in 100,000, although 'piperidyl *iso*amidone' alone shows appreciable coronary dilator activity in concentrations below this figure.

Compound	Toxicity (I.V. mice) mgm./kgm.	Analgesic activity		Respiratory depressant activity	
		Equi-active doses mgm./kgm.	Approximate ratio	Equi-active doses mgm./kgm.	Approximate ratio
Morphine	—	3·0	1·0	4–5	1·0
Amidone	12·5–25*	2·2–2·5	1·3	2·5	1·4–2·0
*iso*Amidone	40	3·0	1·0	7–10	0·4–0·7
'Piperidyl *iso*amidone'	25	3·0	1·0	12	0·3–0·4

* The toxicity of amidone and its optical isomers in mice is greatly influenced by the strain of animals employed, the published figures showing very wide variations.

In man 'piperidyl *iso*amidone' in doses of 12·5 mgm. produced no appreciable side-actions. When the dose was increased to 25 mgm., some of the volunteers described a sensation of warmth, were flushed and slightly dizzy, although the symptoms were less pronounced than those we have observed with other analgesic drugs. This drug was without significant effect upon the cardio-vascular system.

The depressant effect of 'piperidyl *iso*amidone' upon the respiratory response in human subjects to the inhalation of 5 per cent carbon dioxide in oxygen was examined by Prescott, Thorp *et al.*[7], and shown to be far less than that produced by equivalent analgesic doses of morphine, pethidine, amidone, *iso*amidone or Hoechst compound 10582, and to be approximately one third that of morphine.

From the table it would appear that *iso*amidone itself should be a superior drug to amidone; but in a few patients given *iso*amidone it was found that the duration of analgesic action was too short for the drug to be of real value. On the other hand, 'piperidyl *iso*amidone' produced analgesia similar in duration to that of amidone, and has shown sufficient promise to warrant an extensive examination and clinical trials, particularly in obstetrics, and the results of this work will be reported elsewhere.

Note added, January 10. Recently a second nitrile hydrochloride, m.p. 199–200°, isomeric with the hydrochloride of (II), has been isolated and converted into the corresponding ethyl ketone (6-piperidino-4 : 4-diphenyl-3-heptanone, $Ph_2C(COEt).CH_2.CHMe.NC_5H_{10}$) (HCl, m.p. 118–120°). Preliminary results obtained by Dr. A. C. White and Mr. A. F. Green, using young rats, indicate that this ketone is approximately twice as active as morphine analgesically, yet only equal to it as a respiratory depressant.

Constitution and Properties of Laccase

IT was shown that laccase, which had been inactivated by cyanide under certain conditions, could be almost completely re-activated by cupric ions, whereas other metals were ineffective[1]. Further evidence will be presented here to show that copper is an essential constituent of this enzyme. Laccase was purified by the method of D. Bertrand[2,3]. At each successive stage of purification the enzyme activity was measured in the manner previously described[1], and copper and manganese were estimated by microchemical methods[4,5]. Manganese disappears after the first steps of purification; the copper content increases with the Q_{O_2} and remains proportional to activity in all fractions up to the purest preparation having Q_{O_2} 30,000 in presence of *para*phenylene diamine (Fig. 1).

In recent papers, D. Bertrand has described three important properties of laccase which will be re-examined here. It is claimed that the activity of this enzyme is much more sensitive than that of other enzymes to small variations of *p*H [6]. For example, with pyrogallol as substrate, the 'relative Q_{O_2}' is said to fall from 10,000 to 1,500 when the *p*H changes from 6·5 to 7·0. On repeating these experiments, I found that the sensitivity of laccase to *p*H variations is no greater than is generally the case with enzymes, and that optimum activity is observed at *p*H 7·4 with pyrogallol and at *p*H 7·0 with *para*-phenylene diamine (Fig. 2).

Furthermore, D. Bertrand found that laccase, like cytochrome oxidase, has the property of oxidizing cytochrome *c*[7,8] and cystein[9], and this led him to believe that the two enzymes are probably closely related. However, if laccase is added to reduced cytochrome *c* and the mixture shaken in air, no spectroscopic change occurs. The oxidation of cytochrome *c* has also been studied manometrically in the way described by D. Bertrand[7,8]. Thus the oxygen uptake at 20° C. of a system consisting of laccase and 10 mgm. hydroquinone in 3·3 ml. phosphate buffer, *p*H 7·1, was only increased by 5–7 per cent by the addition of 0·2 ml. of 1 per cent cytochrome *c*. Since, however, the quantity of cytochrome *c* used in such experiments is at least thirty times greater than the quantity of laccase (assuming that pure laccase has a Q_{O_2} of 20,000 in the oxidation of hydroquinone), the resulting increase in oxygen uptake is insignificant, and there is thus no indication that cytochrome *c* is oxidized by laccase.

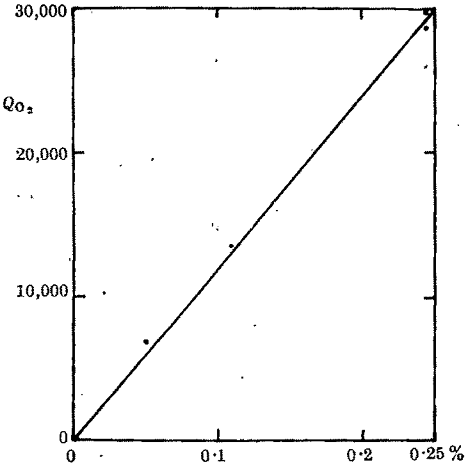

Fig. 1. Relation between the activity of the enzyme (Q_{O_2}) and the copper content

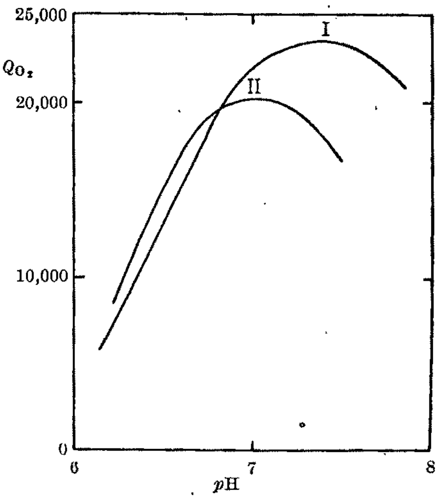

Fig. 2. *p*H curves of laccase activity. Curve I was obtained with pyrogallol and curve II with *para*phenylene diamine

The methyl ester of cystein, as well as cystein itself, is said to be oxidized by laccase[9]. It was claimed that this oxidation has the unusual feature that the *p*H activity curve shows two well-marked optima at *p*H 6·7 and 7·45, at which the rate of oxygen uptake is 31 and 27 per cent respectively of that by hydroquinone at *p*H 6·35. On repeating these experiments in Barcroft manometers, it was found that cystein was not oxidized at all by laccase, even after shaking for thirty minutes. The slow rate of oxygen uptake observed with laccase and cystein methyl ester represented only 5–8 per cent of that found with laccase and *para*phenylene diamine. Moreover, a study of the effect of *p*H on this slow oxidation revealed not two optima, but one at 7·1, and the *p*H activity curve was of the usual type. As laccase does not oxidize cystein, and as its effect on the methyl ester is very small, the conclusion that cystein can be oxidized directly by laccase is not justified.

Investigations with Radioactive Penicillin

MUCH of the published data regarding the mode of action of penicillin is necessarily concerned with secondary effects on bacteria, for example, rate of killing under different conditions, morphological changes, etc. By use of radioactive penicillin, it should be possible to find out directly something of the nature of the primary reaction between penicillin and the cell.

In a previous communication[1], we have described attempts to measure the amount of penicillin involved in the killing of bacteria, which gave no positive

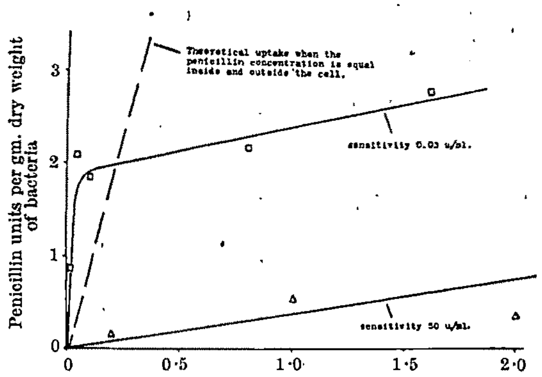

Fig. 1. Penicillin uptake on resting staphylococci

results. In these preliminary experiments we assumed that self-absorption of the β-rays by bacteria would be considerable, and accordingly looked for a disappearance of radioactivity from the filtrate, rather than an increase on the bacteria. Further experiments have shown that this self-absorption effect can be eliminated by counting thin films of bacteria, and under these conditions we have been able to detect a penicillin uptake.

Bacteria were suspended under various conditions in radioactive penicillin solutions, centrifuged, washed and the radioactivity on the bacteria measured directly by the Geiger counter, the uptake being expressed as units of penicillin per gm. dry weight of the cells, as this avoids any assumptions regarding size of bacteria, etc., made when calculated in terms of molecules attached per organism. The penicillin uptake is very small, varying from a maximum of 40 units per gm. dry weight down to the smallest detectable amount of 0·5 units per gm., this variation depending on the strain of the organism and conditions of experiment.

Penicillin is taken up by all bacteria in amounts which increase with penicillin concentration in the external environment. In the range of 0–0·5 u./ml., however, there is a marked qualitative difference in the shape of uptake curve for sensitive and resistant organisms (see Fig. 1), so that, at these minimal concentrations, much more penicillin is fixed by sensitive than by resistant bacteria. There is, in fact, a direct correlation between the sensitivity of an organism and the amount of penicillin attached to it. The uptake increases greatly when growth occurs in presence of penicillin (see Fig. 2). However, if growth is halted by cooling, or if the cells are already dead, there is still a rapid but smaller uptake.

The penicillin is strongly and irreversibly attached under all conditions of reaction, and cannot be removed by washing or by incubation for 30 min. with 0·1 per cent cetyl trimethyl ammonium bromide or 'Aerosol OT', 5 per cent phenol, 1 per cent cysteine, 1 per cent sodium hydroxide, *N* hydrochloric acid, 1 per cent glucose or with ordinary penicillin (200 u./ml.); it is, however, removed by heating for five days at 60° C. in water.

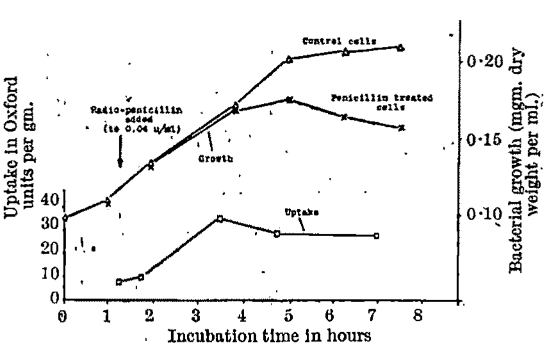

Fig. 2. Rate of penicillin uptake on actively dividing staphylococci

The site at which penicillin is attached to resting cells is not blocked by pre-treatment of the cells with 3 per cent formalin, 0·1 per cent cetyl trimethyl ammonium bromide, 0·1 per cent euflavin, *N* hydrochloric acid, or by autoclaving; but heating for five days at 60° in water or pre-treatment with penicillin or acetic anhydride completely prevents any uptake.

Whatever the nature of the primary site of penicillin action, it is clear from this and other work that rapid growth exposes more centres in the bacteria with which the penicillin can react. The combination must either be by unusually strong adsorptive or by chemical forces.

We are grateful to Dr. E. Lester-Smith for further preparations of radiopenicillin and to Mr. P. Roberts for his help in maintaining the counter.

Electrophoretic Properties and Analysis of Whale Myoglobin

IN a recent note[1] describing the preparation of whale myoglobin, it was shown that this protein could be crystallized as the carboxy- or met-myoglobin.

In continuation of this work, an electrophoretic study has been carried out using the Tiselius apparatus. The myoglobin was dissolved to give a 1 per cent solution in phosphate buffers of ionic strength 0·1 at *p*H values between 4 and 11. Only above *p*H 11 or below *p*H 4·6 was a single boundary observed. At all intermediate *p*H values two or three boundaries were present.

Globin hydrochloride was prepared by the method of Anson and Mirsky[2], which has already been used with success by Drabkin[3] in the case of horse myo-

globin. The native product became denatured readily, though in two out of six experiments a clear solution was obtained in 3 *M* phosphate buffer at *p*H 7·0. Such solutions nevertheless were too unstable for electrophoretic examination. The denatured globin, which was soluble below *p*H 4·0 and above *p*H 10·0, gave the expected picture of a single sharp ascending boundary with a very diffuse descending boundary.

A preparation of the globin, obtained by precipitating twice with acetone–hydrochloric acid followed by heat coagulation, contained 17·0 per cent nitrogen, corrected for ash. Amino-acid analyses were made by methods in current use in this laboratory, and the results are collected in the accompanying table. The minimum molecular weight would appear to be about 16,700. Application of the end-group assay method of Sanger[4] suggests that the molecule may be a peptide chain bearing a terminal valyl residue.

I wish to thank Prof. A. C. Chibnall for his advice and encouragement, and the "Stiftung für Stipendien auf dem Gebiete der Chemie" for a grant.

Role of Substances Formed during Germination in the Growth of Plants

IN this laboratory, v. Hausen[1] showed in her doctoral thesis that if the cotyledons of a pea plant are removed after a germination period of five to nine days, and the cotyledonless seedling is transferred into a sterile nutrient solution (the sterile culture system of Virtanen and v. Hausen[2]), it grows at first poorly and small chlorophyll-containing leaves are formed; but growth soon ceases. If crystalline ascorbic acid (30–40 mgm. per pea plant) was added to the nutrient solution (1 litre per pea plant) the plant grew until the flowering stage. Since the cotyledons of the pea at this stage of development contain more than 90 per cent of the vitamin C formed during germination, this experiment gave convincing proof for the conclusion[3] drawn from the previous observations that vitamin C is a growth hormone of plants and indispensable for their life.

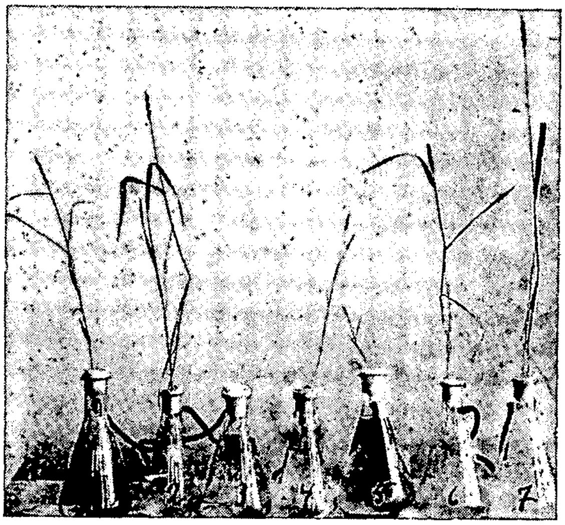
This problem has again been under investigation in this laboratory during the last two years. Saubert-v. Hausen[4] has already reported on experiments which show that the B-complex and biotin also promote to a certain extent the growth of cotyledonless peas. The effect of vitamin C is, however, much superior. The effects of various vitamins are additive.

The purpose of our new experiments has been in the first place to clarify the mode of action of vitamin C. At first we found that large doses of vitamin C (100–120 mgm. ascorbic acid per pea plant, administered in three doses) produced in some cases with cotyledonless seedlings a growth comparable with the normal growth. In the previous experiments with smaller doses of vitamin C (30–40 mgm.) the growth was much weaker. Our experiments showed also that amino-acids and especially the expressed juice of the growing pea promote to a certain extent the growth of cotyledonless peas. The growth was, however, not comparable with the response obtained with vitamin C.

All the experiments reported above were performed in nutrient solutions with calcium nitrate as the source of nitrogen. As the idea that ascorbic acid would function as a reducing system did not seem impossible, we carried out a number of experiments using ammonium sulphate as the source of nitrogen. The experiments were made both with cotyledonless peas and endosperm-free wheat plants. In the wheat grain, the vitamin C content of the embryo increases during two or three days to such an extent that the vitamin C content of the endosperm largely loses its significance. The wheat embryo must therefore be removed from the endosperm at a very early stage in order to obtain a distinct response to the vitamin C addition to the nutrient solution. In our experiments the wheat embryo was excised one or a few hours after the moistening of the seed. From a pea plant, in which vitamin C accumulates in the cotyledons, these were removed four to five days after moistening the seeds.

The results with wheat have shown consistently in all experiments that the excised embryo grows very poorly in a nutrient solution where nitrate is used as the source of nitrogen unless supplied with vitamin C. In a nutrient solution containing vitamin C the growth is again good. When ammonium sulphate is used as the source of nitrogen, the wheat embryo grows fairly well without vitamin C, nor does the addition of vitamin C improve the growth; on the contrary, it depresses growth to some extent (see photograph).

With pea the results in nutrient solutions with ammonium salts are not so distinct and consistent as with wheat. Difficulties are added in the first place by the fact that the pea takes up ammonium ions so rapidly[5] that ammonium salts in amounts injurious to growth are easily accumulated in the



Effect of ascorbic acid and different sources of nitrogen on the growth of isolated wheat germs

No. of expt.	Additions	Source of nitrogen	Dry weight of seedling (mgm.)	Length of shoot (cm.)
1	None	$(NH_4)_2SO_4$	520	37
2	,,		720	46
3	,,	$Ca(NO_3)_2$	11	11
4	,,	,,	123	28
5	,,	,,	38	12
6	Vitamin C	$(NH_4)_2SO_4$	370	37

plant. The light conditions and other factors affecting growth determine whether the pea grows well on ammonium salts or whether it withers. All this makes it difficult to carry out experiments on peas with ammonium nitrogen. In any event, even with peas a fairly good growth was induced in some experiments by means of ammonium sulphate without addition of vitamin C, and no improvement of growth resulted from vitamin C administration. In most cases the addition of vitamin C was harmful, perhaps because the oxidation-reduction potential was lowered too much.

The results suggest that the effect of vitamin C in plants is at least partly based upon the reducing properties of this vitamin. Regulation of the redox potential is apparently the important function of this vitamin in plants.

Our results show likewise that the prevailing concept that immediately after the appearance of chlorophyll the plant forms all its organic material through assimilation of carbon dioxide, in other words, is autotrophic for its metabolism, does not as such hold good. The plant needs the substances formed in the seed during germination often for a long time after the development of the first green leaves. This period varies in different plants.

The close dependence of the growth of plants on the substances formed in the seeds suggests that the productiveness of the different varieties of the same plant may perhaps depend on the quantity of such substances formed during germination. The elucidation of this problem, which is of much interest for the breeding work, requires extensive analytical material.

Note added in proof, March 12. Later experiments have confirmed the view that the reducing properties of vitamin C are of high significance. In addition to vitamin C many other substances, such as reductone, cysteine and glutathione in suitable concentrations promote growth in nutrient solutions with nitrate as the source of nitrogen. With ammonium salts these reducing substances are either ineffective or, in somewhat higher concentrations, injurious. Our measurements have also shown that vitamin C as well as other reducing substances added to the substrate lower the redox potential within the plant. Except in the above-described system, we have examined the growth of germs also in the dark on agar substrate which in addition to mineral salts contained 4 per cent[6] cane sugar. Generally the results were in agreement with those above.

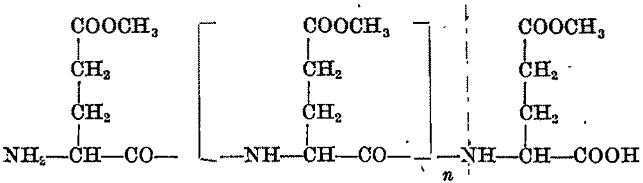
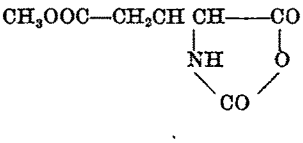
Evidence of Chain Folding in a Synthetic Polypeptide and in Keratin

A STUDY of polypeptides prepared by Leuchs's method[1,2] is being carried out in this Laboratory. We have recently prepared the polypeptide I (below) by the polymerization of the N-carbonic anhydride of γ-methyl L-glutamate (II), and wish to describe here observations which indicate that it has a folded structure as shown in III.



$NH_2-CH(CH_2CH_2COOCH_3)-CO-\left[-NH-CH(CH_2CH_2COOCH_3)-CO-\right]_n-NH-CH(CH_2CH_2COOCH_3)-COOH$

(I)



(II)

A small number of initiating centres were formed by exposing the anhydride to water vapour, and the specimen was left to polymerize in the solid state for three months in a desiccator. The polypeptide prepared in this manner was insoluble in the usual organic solvents; it dissolved readily in formic acid and slowly in *meta*-cresol. The specific viscosity measured in *meta*-cresol was 0·42 ($C = 1{\cdot}00$ gm./100 c.c.), corresponding to a molecular weight of about 30,000.

Films of the polypeptide could readily be cast from hot *meta*-cresol solution; these films were coherent and pliable. A film of the polypeptide was cast on a thin smooth sheet of cadmium and rolled to produce an extension of 500 per cent. After rolling, the film was still coherent and flexible and showed double refraction, the maximum polarizability being in the direction of extension ($\Delta n = 0{\cdot}0076$).

The spectrum of the extended film was examined by a polarizing infra-red spectrometer of high resolving power. The optical density of the specimen could be measured accurately with the electric vector of the incident radiation parallel and perpendicular to the direction of extension[3]. The results obtained in the 3 μ-region of the spectrum for bands which could be accurately analysed are given in the table.

Polyglutamic ester stretching-frequencies

Band frequency	Assignment	Dichroic ratio
3,305 cm.$^{-1}$	N—H stretching (hydrogen-bonded)	1·26
3,076	N—H vibration	1·80
2,851	CH_3 or CH_2 symmetrical stretching	0·60

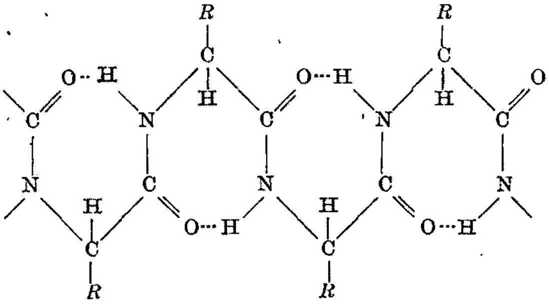
The dichroic ratio is the ratio of the optical density of the absorption band with the electric vector parallel to the direction of extension to the density with the electric vector perpendicular to this direction.

The bands at 3,305 and 3,076 cm.$^{-1}$ are practically identical with those of nylon 66 (3,308 and 3,078 cm.$^{-1}$), and are characteristic of many mono-substituted amides and polyamides. The band at 3,305 cm.$^{-1}$ is due to the N—H stretching-frequency in the hydrogen-bonded state. The band at 3,076 cm.$^{-1}$ may either be an overtone of the 1,550 cm.$^{-1}$ frequency or it may be due to the N—H stretching, accompanied by close hydrogen-bonding such as may occur in nylon. It is certainly an N—H frequency, and has been discussed from this point of view by Astbury, Dalgliesh, Darmon and Sutherland[4].

Polyglutamic ester shows the surprising result that the maximum absorption due to both bands is parallel to the direction of extension, which indicates that the N—H bonds tend to lie parallel to the chain axis. The dichroic ratio is not large and suggests merely a preferred orientation of the N—H bond towards the chain axis. By examining the specimen with the radiation incident in several different directions, it has been shown that the above result is not due to the unlikely event of the chains being oriented perpendicular to the direction of rolling. Preliminary observations on the band at 1,650 cm.$^{-1}$ due to the peptide C : O stretching-frequency also indicate that the C : O bond is parallel to the chain axis.

In a rolled specimen of nylon 66 [3], both the N—H bands and the C : O band show stronger absorption perpendicular to the chain axis, as is to be expected in the extended form of the chain where the N—H bonds lie in planes perpendicular to the chain axis.

These results can be explained if the peptide chain is folded and maintained in the folded state, in spite of the extending force, by *intra*-chain hydrogen-bonding between the N—H and C : O groups (III), in which the N—H groups are inclined towards the chain axis.



(III)

It is likely that this folding is a direct consequence of the steric hindrance to *inter*-chain hydrogen-bonding, produced by the bulky side-chains. The folding of peptide chains in natural proteins has, of course, been suggested by Astbury[5]. Picken[6] has suggested that protein chains can exist in various configurations with the same internal energy, the extended form being the least probable. The folded configuration proposed for rolled polyglutamic ester should possess the same internal energy as the *inter*-chain hydrogen-bonded peptide. It may be that this folded structure exists largely in the non-crystalline regions of the polymer.

Results similar to the above have been obtained with a polyglutamic ester of molecular weight about 15,000 prepared by polymerization in solution.

Polarized infra-red observations of the highly oriented α-keratin obtained from the quill tip of *Atherurus africanus* have also given results similar to the synthetic polypeptide. MacArthur[7] has shown that porcupine quill is one of the most highly oriented available forms of α-keratin. The infra-red results indicate that α-keratin is also folded in the same way as the synthetic polypeptide and forms an extended ribbon-like molecule. The side-chains and seven-membered rings will both lie approximately in the plane of the ribbon. Huggins[8] has suggested the possibility of a similar seven-membered ring for α-keratin, but has adopted a different arrangement of the *R* and H groups about the asymmetric carbon atom. He also favours an arrangement with close spiralling of the ribbon. A spiral structure in a closely packed system does not seem to be consistent with the ease of effecting the α-β transformation, and a close spiral certainly will not account for the infra-red results.

Infra-red and X-ray investigations are now being carried out on other synthetic polypeptides and proteins.

Structure of Chitosamine

In a recently published paper[1], it was shown that a number of aldose sugars are oxidized at characteristic rates by the action of hypoiodous acid. The rate of oxidation appears to be related to the structural configuration for any particular aldose; thus glucose and xylose show a similar rate of oxidation, which is, however, different from that shown by galactose and arabinose, and different again from that shown by mannose. The magnitude of these variations in the rate of oxidation is sufficiently great to enable a positive identification of the configurational group to which any one of these aldoses may belong. This work (*loc. cit.*) suggested that kinetic measurements of the hypoiodous acid oxidation of sugar derivatives of the aldose type might yield valuable information on the structure of such derivatives.

Chitosamine hydrochloride, for a pure sample ($\alpha_D^{20} = +72{\cdot}5$) of which, prepared from the carapace of *Jasus Lalandii*, I am indebted to Dr. J. B. Polya, was submitted to the oxidation procedure, and its rate of oxidation found to coincide closely with that of the galactose–arabinose group of aldoses. The experimental results are shown in the accompanying table, glucose and mannose being added for purposes of comparison.

Time of quarter change (sec.)

*p*H	Chitosamine hydro-chloride	Galactose	Arabinose	Glucose	Mannose
10·55	4·25	4·25	4·25	6·5	28
10·95	3·25	3·25	—	4·5	18·5
12·80	15·0	16·25	16·0	32·0	175

This result is surprising, since the configuration of chitosamine has generally been accepted on what appears to be reliable evidence as that of glucose[2].

The results reported here may indicate, therefore, that chitosamine in strongly alkaline solution exists in some other modification than a pyranose ring (possibly a high percentage of the free aldehyde form), since only those aldoses which have a pyranose ring have been studied in previous oxidation experiments[3]. The products of the oxidation reaction are at present being examined with the view of clarifying this point.

Stability of Aminobenzyl-Quaternary Salts

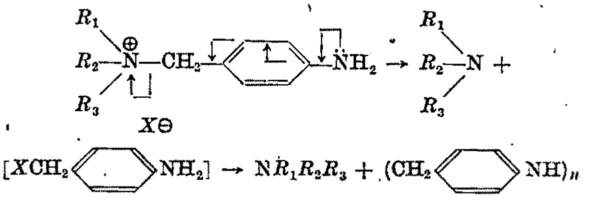
While engaged in the preparation of benzyl-quaternary salts of a number of N-heterocyclic ring systems, the abnormal instability of some salts containing the aminobenzyl group was observed.

When, for example, *o*- or *p*-nitrobenzylquinolinium chloride was reduced under neutral conditions (ferrous hydroxide or iron powder and water), the desired amino-compound was difficult to isolate, and the only recognizable product (yield *c*. 80 per cent) was quinoline. The first conclusion, that here was a particularly facile case of reductive debenzylation, had to be abandoned on further investigation. Thus, when *p*-nitrobenzylquinolinium chloride was hydrogenated in aqueous solution in the presence of palladium–charcoal and more than one mole of hydrochloric acid, six hydrogen atoms were absorbed, and the filtrate could be evaporated in a vacuum at a low temperature to leave *p*-aminobenzylquinolinium chloride hydrochloride as almost colourless hygroscopic crystals. In the dry state this was fairly stable over several weeks, and in solution it could be diazotized normally and coupled, for example, with β-naphthylamine in acid solution. The colourless solution of the hydrochloride, on treatment with sodium acetate, turned orange and deposited orange-yellow needles of the free amino-compound. This had a very low order of stability. It could be dried rapidly in a vacuum and analysed, but could not be recrystallized; warmed gently with water, it first dissolved but then rapidly decomposed to give quinoline in high yield and a brown amorphous material. In the dry state decomposition was apparent after a few days. Acetic anhydride converted the aqueous suspension into *p*-acetamidobenzylquinolinium chloride, a crystalline substance stable to boiling water.

On the other hand, *m*-aminobenzylquinolinium chloride hydrochloride, prepared in a similar manner to the *p*-isomer, was a non-hygroscopic substance, the aqueous solution of which was quite stable to boiling after the addition of sodium acetate. The free amino-quaternary iodide formed orange-red crystals from methanol.

Further work has since shown similar properties (*p*-amino, unstable; *p*-acetamido- and *m*-amino, stable) in the aminobenzyl-quaternary salts of *iso*quinoline, pyridine and phenyldimethylamine, as well as a number of *bz*-substituted quinolines. In the case of *p*-aminobenzylpyridinium chloride, the facile decomposition was probably observed by Lellmann and Pekrun[1]; but the significance was not explained.

It is suggested that the explanation for these observations may be that shown diagrammatically below; the strain in the benzyl-N bond due to the



presence of the adjacent positive charge is magnified to the point of actual rupture by the electromeric effect of a *free* amino-group in the *o*- or *p*-position. The greater stability of the *m*-isomer as well as that of the salts and acetyl-derivatives of the *o*- and *p*-isomers follows logically, while the amorphous substance which always accompanies the tertiary amine is seen to be probably the polymeric benzylene-imide.

It is hoped to publish fuller details of this work later.

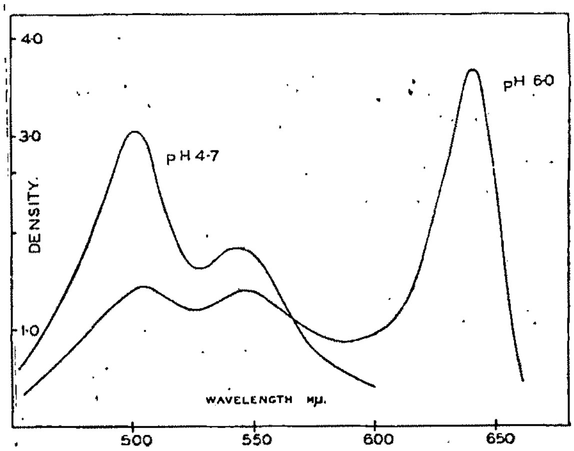
Use of Dyes to Determine the Iso-electric Point of Gelatin

The effect of small concentrations of gelatin on the absorption characteristics of aqueous solutions of certain carbocyanine dyes has been reported by Sheppard[1] and Solovyev[2].

During an investigation of some of the factors influencing the adsorption of these dyes to proteins, it was noted that the adsorption is electrostatic in character and depends upon the *p*H of the gelatin solution. Certain dyes exhibit a narrow and intense absorption band in the red region of the spectrum in dilute gelatin solutions (0·01 per cent) if the *p*H is above the iso-electric point. Below the iso-electric point the absorption is similar to that of the aqueous dye solution. The colour change is sharp and is illustrated by the absorption curves in the accompanying diagram.



The absorption of 1 : 50,000 3 : 3′-dimethyl 5 : 5′-dichloro-9-ethyl thiacarbocyanine chloride in 0·01 per cent aqueous gelatin solution at two *p*H values

This effect provides a quick and convenient method for the determination of the iso-electric point of gelatin. The following technique has been found to give reliable and reproducible results. Several dyes were examined and the one selected was chosen for sharpness of end-point.

To 50 ml. distilled water add 0·5 c.c. of 1 per cent gelatin solution followed by 0·5 c.c. of 1 : 2,000 ethyl alcohol solution of 3 : 3′-dimethyl 5 : 5′-dichloro-9-ethyl thiacarbocyanine chloride. If, as usual, the *p*H of the solution is above the iso-electric point, the colour will be blue. *N*/100 hydrochloric acid is added from a micro-burette until the colour of the solution changes from blue to red. Each addition of acid is followed by thorough stirring of the solution. The end-point is reached when the last trace of blue colour just disappears from the solution. Measurement of the *p*H of the solution at this stage gives the iso-electric point. If the end-point is overshot, addition of a slight excess of alkali will enable the titration to be repeated, and by this method several estimations can be made on one sample.

A comparison of the dye method with the spirit precipitation method[3] is given in the following table, using four different gelatins. The figure given for the dye method is the mean of four estimations.

Gelatin	Iso-electric point	
	Dye	Spirit precipitation
A	*p*H 5·05	*p*H 4·95
B	4·75	4·75
C	4·87	4·85
D	5·05	5·05

The end-point with acid-washed gelatins of high iso-electric point (*c.* 8·0) is not so sharp, but with these gelatins the spirit precipitation method also gives indeterminate results. The dye method has the advantage that an estimation can be made on as little as 5 mgm. of the gelatin.

Inhibition of the Low-Temperature Polymerization of *iso*Butene

R. M. THOMAS *et al.*[1] have stated that the presence of olefines diminishes the yield of the low-temperature polymerization of *iso*butene by Friedel–Crafts catalysts and also reduces the molecular weight of the product. Plesch, Polanyi and Skinner[2] have reported that ethanol or diethyl ether inhibit the same reaction when using titanium chloride ($TiCl_4$) and traces of water as catalyst, even if the titanium chloride is in excess of the inhibitor; and Plesch[3] has shown acetic acid to be an inhibitor. Norrish and Russell[4] have reported that the rate of the low-temperature polymerization by stannic chloride is decreased by ethanol, *t*-butanol, diethyl ether, acetone, butene-1 and butene-2; and that the first four of these substances also reduced the molecular weight of the product.

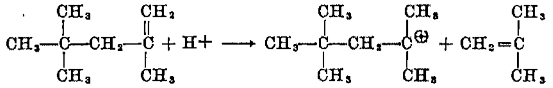
We have investigated the effect of inhibitors on the low-temperature polymerization of *iso*butene by boron trifluoride (BF_3). The reactions were carried out adiabatically and were followed in terms of the temperature rise, due to the heat of polymerization, by means of a thermocouple. The reaction vessel was part of a vacuum system, and the required volume (50 ml.) of monomer solution in hexane (10 per cent vol./vol.) could be syphoned into it from the reservoir with complete exclusion of the atmosphere. The inhibitor was added by condensing into the reaction vessel a known quantity of the inhibitor vapour. When the mixture of solvent, monomer and inhibitor had been brought to a temperature near − 65° C., the reaction was started by circulating a fixed volume of boron trifluoride and nitrogen (containing $7 \cdot 5 \times 10^{-3}$ gm. mol. BF_3) continuously through the solution. This circulation was carried out by an all-glass magnetically operated pump working in a closed circuit.

The mean molecular weights of the polymers were calculated from the intrinsic viscosities of their solutions using the Houwink equation[5] and the constants determined by Florey[6]. The yields were measured both by estimating the bromine consumed by the residual monomer and by weighing the polymer precipitated in alcohol and dried.

The yield of polymer was high (88–100 per cent) and not affected by the inhibitors used. In the absence of inhibitor, the reaction-rate decreased monotonically from its initial maximum value, the temperature rise (24–27° C.) was completed in 35–45 sec., and a product of molecular weight 40,500–55,000 was obtained. The presence of *t*-butanol and ether produced markedly *S*-shaped time–temperature curves analogous to those observed in free-radical polymerizations and possibly having a similar explanation[7].

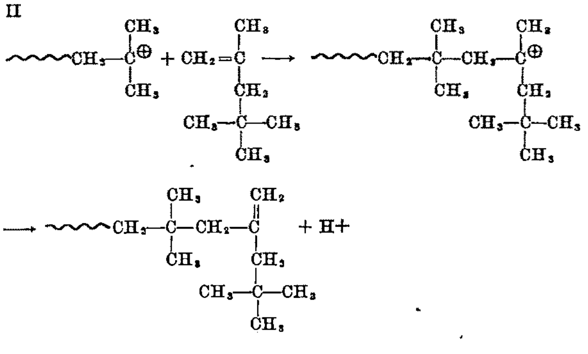
With 3×10^{-3} gm. mol. *t*-butanol or ether present, the time of reaction increased to 160 and 200 sec. respectively, and in the case of *t*-butanol gave molecular weights of polymer of 11,100–13,700. The addition of the same quantity of di-*iso*butene (a mixture of 2,4,4-trimethyl pentene-1 and -2) reduced the molecular weight to 5,600 but left the reaction time at 40 sec., as in the uninhibited experiments. Thus *t*-butanol and di-*iso*butene both increase the rate of chain termination; but *t*-butanol reduces the rate of chain initiation (by complex formation with boron trifluoride), and di-*iso*butene leaves this rate unaffected. A possible explanation of the di-*iso*butene case in terms of the carbonium ion theory of Friedel–Crafts polymerizations[8,2] and the steric properties of the structures involved is that an activated di-*iso*butene molecule may start a chain (I), but the incorporation of di-*iso*butene in a growing

I



⟶ Uninhibited propagation.

II



Further propagation sterically inhibited by neopentyl group.

chain (II) terminates the latter due to the steric hindrance to any further step[9,10].

The terminated chain in II can start another chain by proton transfer, thus permitting an original initiation process to cause the same total amount of polymerization with and without di-*iso*butene but giving lower molecular weights in its presence.

We are informed by A. G. Evans and G. W. Meadows that they have established the occurrence of a high degree of chain transfer for the reaction of *iso*butene in the presence of boron trifluoride–cocatalyst complexes. Their results have been submitted for publication elsewhere[11].

Streaming Potential in Paper Chromatography

The net resultant flow of solvent through the capillary channels of paper used in chromatography is in a direction away from the point of feed; and it was therefore considered possible that such a system might result in the setting up of a streaming potential[1].

This has been verified experimentally in some cases, using water and inorganic salt solutions: distilled water flowing through a washed and dried strip of No. 3 Whatman paper showed a potential gradient of approximately 10 mV. per cm. measured by a Cambridge *p*H meter. With 1 per cent thorium nitrate solution in place of water, the potential was reduced almost to zero. 1 per cent sodium chloride solution showed a potential gradient of approximately 4 mV. per cm. Various factors, such as rate of flow of liquid, and nature of electrodes used in making the measurements, may affect the values considerably.

Such potentials (or their causes) may well exert a marked effect on the process of chromatographic development, and preliminary experiments in which the potentials have varied have given interesting indications. For example, development of 0·01 ml. of 0·1 per cent aqueous solution of a mixed colour (Edicol Green 37113, I.C.I., Ltd.) with distilled water failed to separate the components, the band moving with the solvent front, whereas development with 1 per cent sodium chloride solution achieved complete separation into blue and yellow bands. Very dilute solutions of aluminium chloride and thorium nitrate caused strong adsorption of both components, which is difficult to attribute to 'salting out' effects[2] in view of the low salt concentrations, and more probably relates to changes in the electric double layer.

Indications have been observed using either the strip or central feed technique[3] that the flow of one liquid over another occurring in 'partition' chromatography may result in streaming potentials of varying sign, which may be significant in considering possible mechanisms of 'partition' separations.

A study of the above and related phenomena is in progress and will be reported more fully elsewhere.

Dielectric Properties of the Human Body in the Microwave Region of the Spectrum

As a preliminary to a detailed study of the reactions of certain body tissues to electromagnetic radiations on centimetre wave-lengths, it has been found desirable to determine the propagation characteristics of such waves in various parts of the body.

The specimens were obtained in most cases from surgical operations, being selected for homogeneity and cut into sections suitable for insertion in a wave-guide cell. In this cell the specimen was trapped between a tight-fitting plug of polystyrene one half wave-length in thickness and a reflecting metal plunger driven on a micrometer screw thread. The cell was surrounded by a bath of water thermostatically controlled at a temperature of 37° C. to an accuracy of $\pm \frac{1}{2}$° C.

From measurements on the standing wave pattern set up in the wave-guide feeding the cell, two constants α and β for the medium were determined by a method similar to that used by Roberts and von Hippel[1]. The parameter α is the absorption coefficient and is expressed in nepers/cm. The parameter β is the phase constant expressed in radians/cm. and is a measure of the velocity of the wave in the medium. To a first approximation the dielectric constant of the medium can be taken as proportional to β^2.

The following representative body constituents have been measured in this way at a wave-length of 3 cm., several thicknesses from various specimens being used where practicable (Table 1).

The results quoted in Table 1 should have a measurement accuracy better than ± 5 per cent in α and ± 1 per cent in β; but the difficulty of repeating biological specimens accurately should be appreciated. Measured in the same equipment, the corresponding constants for distilled water at 37° C. were $\alpha = 2{\cdot}70$ and $\beta = 16{\cdot}0$, which are in good agreement with those obtained by Collie, Hasted and Ritson[2].

Examination of the results for biological materials leads to the following general conclusions.

(1) The absorption coefficients at 3·18-cm. wave-length for a large number of body constituents are substantially the same as that of water at the same temperature. Fatty tissue and bone have a considerably lower absorption, and are relatively transparent to the radiation.

(2) The phase constants for a large number of body constituents fall into a group with a rather lower average value than that of water. Small, but significant, differences occur within the group, presumably attributable to the variation of water content. This is demonstrated by results taken on

Table 1

Specimen	α (nepers/ cm.)	β (radians/ cm.)	Remarks
A. Normal			
Whole blood	2·90	13·5	Uncoagulated by 1/500 mgm. heparin
Skin 1. Breast	2·65	12·1	Free of areolar tissue
2. Leg	2·55	11·8	
Muscle (skeletal)	2·50	11·7	Stripped of fascial sheath
	2·70	11·6	
Sigmoid colon	2·75	13·5	Sections included muscle coats, but no serous coat
	2·70	13·4	
Tænia coli	2·85	13·6	
Thyroid gland	2·70	13·7	Hyperplastic
	2·85	13·5	
	2·65	13·5	
Prostate gland	2·70	13·7	Hyperplastic
	2·50	13·7	
Fat 1. Breast	0·49	4·0	Free of areolar tissue
2. Leg	0·44	4·0

B. Malignant			
Carcinoma of breast (scirrhus)			
(*a*)	2·70	13·1	Sections were taken from four different tumours and all were confirmed scirrhus carcinoma of breast by histological examination. The only difference revealed was in the degree of fibrous stroma present in each tumour section
	2·75	12·5	
(*b*)	3·0	13·1	
	3·2	13·0	
(*c*)	2·75	12·5	
(*d*)	2·65	12·5	

Table 2

Specimen	Corpuscle concentration (× 10^6 per c.mm.)	Radians/cm.	Dielectric constant relative to air
Blood serum	—	15·2	57
Whole blood	4·9	13·5	45
Corpuscles in high concentrations	17·1	12·7	40

whole blood and its products after centrifuging (Table 2).

Fatty tissue and bone have correspondingly lower dielectric constants, of the order of 4·5 and 8·0, respectively.

(3) At this wave-length no significant difference may be expected in the behaviour towards the radiation of malignant and non-malignant tissue. It is to be expected that the effect of the polar water molecules will overshadow any changes which may result from biologically different structures.

Consider 3-cm. wave-length radiation falling normally from outside on an area of the body, which can be treated for this purpose as a uniform and infinitely extended medium with average values of the constants α and β. Calculation shows that approximately one-third of the incident power will be absorbed by the body, the remainder being reflected. The high value of the absorption coefficient indicates that the majority of the absorbed power will be dissipated initially in the first few millimetres of skin. The resulting heat distribution will normally be modified by conduction and by the action of the vascular system.

These dielectric measurements are being extended to 10-cm. and 1·25-cm. wave-lengths.

The work has been carried out at the Royal Victoria Infirmary, Newcastle upon Tyne, with the aid of a grant from the North of England Council of the British Empire Cancer Campaign. The assistance of Ministry of Supply, Telecommunications Research Establishment, in supplying electronic equipment is also gratefully acknowledged.

Wound Extracts and their Effects on the Growth of Hen Fibroblasts

STERILE, healing wounds (rats) were extracted with physiological salt solution. Extracts were made from wounds of ages from 1 to 12 days. The extract was dialysed with several changes of distilled water at a low temperature in a 'Cellophane' tube. In this way the albumin and globulin fractions of the extracts could be separated. Both solutions were then brought to *p*H 6·5–7 and diluted to the same dry-weight concentration. The usual heart fibroblast cultures in Carrel flasks and Carrel glasses were later treated with the prepared extracts. The results are given in Fig. 1, in which the zero horizontal line represents the usual index of increase for the corresponding control culture. A minus index means growth inhibition, and a plus index represents increase of growth.

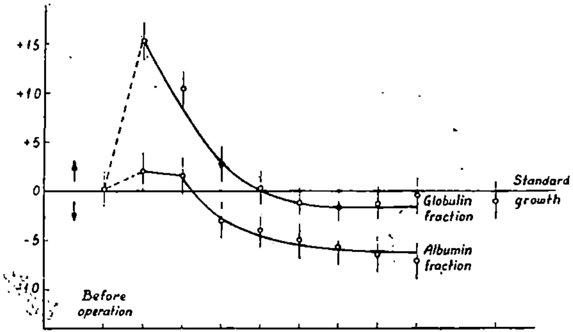

Fig. 1

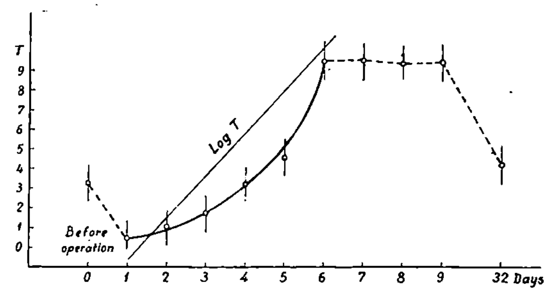
The power of the wound to combine with basic dyestuff was also investigated. By a previously developed method (Balazs) the amount of dyestuff that the tissue bound was quantitatively ascertained. Frozen sections of wound preparations (100 μ) were later weighed and laid in a specific concentration of toluidine blue in water solution. The preparation



$T = 10^{-3}$ mgm. dyestuff per mgm. tissue
Fig. 2

remained in this solution for 24 hours at + 3° C. Then the concentration of the coloured solution was ascertained photometrically, and from the figures obtained the amount of dyestuff absorbed per mgm. tissue was calculated. The results are given in Fig. 2.

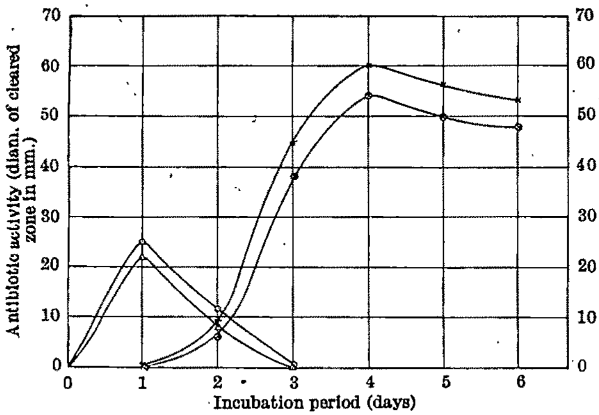
Antibiotic Activity as Shown by a Highly Amylolytic Strain of *Bacillus subtilis*

In the course of an investigation on the formation of amylase by *Bacillus subtilis*, it was observed that the organism, when grown on wheat bran medium, showed a pronounced antibiotic activity. The maximum activity was found in the aqueous extract from a 24-hour-old culture. The amylase formation during this period was found to be low, but steadily increased with further incubation. This phenomenon led to a study of the relationship between the antibiotic production and amylase formation by *B. subtilis*[1] (N.C.T.C. : 2027 *N*) when grown on wheat bran.

The production of substances of antibiotic nature by *B. subtilis* has been studied by earlier workers. It has been shown that three compounds, bacillin, subtilin and bactracin, which are characterized by their bacteriostatic and lytic actions on different Gram-positive and Gram-negative organisms, are synthesized by the various strains of *Bacillus subtilis*. Recently, work has been conducted employing wheat bran as a whole or wheat bran extracts for culturing *P. notatum*[2,3]. These observations indicate the possibility of increasing the penicillin yield by about 60 per cent. It has been suggested that as wheat bran has a fairly high fat content, the fatty acids liberated during the growth of fat-splitting organisms are responsible for the antibiotic action. No direct proof has, however, been advanced to demonstrate the origin of the antibiotic substances from fatty acids.

Bacillus subtilis was grown on wheat bran (10 parts) moistened with the phosphate buffer solution (*p*H 7·0; 25 parts) for the production of amylase[4]. A control series using de-fatted wheat bran was also run along with the experimental series. The extracts were made with water (25 parts) at intervals of every 24 hours. The mass was then strained through cheese cloth and the extract filtered through Whatman's filter paper No. 42. The amylase and antibiotic activities of the clear filtrates were then determined. The antibiotic activity was tested against *Staphylococcus aureus*, by the cup assay method[5]. The results obtained are given in the accompanying table.



Amylase and antibiotic activity of *B. subtilis*. ×—×—, ⊙—⊙—, wheat bran whole; ⊕—⊕—, △—△—, wheat bran de-fatted

Age of the culture (days)	Amylase activity (units per ml.)		Antibiotic activity (diameter of the zones in mm.)	
	Whole wheat bran	De-fatted wheat bran	Whole wheat bran	De-fatted wheat bran
1	Negligible	Negligible	25·0	22·0
2	9·0	6·5	11·0	8·0
3	45·0	38·0	Negligible	Negligible
4	60·0	54·5	,,	,,
5	55·5	50·0	,,	,,
6	53·0	48·0	,,	,,

The results show that an active strain of *B. subtilis* is able to synthesize antibiotic substances during the earlier stages leading to the production of amylase. This antibiotic activity cannot be attributed to the liberation of fatty acids, because the activity is developed even on de-fatted bran.

The antibiotic activity is at a maximum on the first day of growth and gradually disappears with extended incubation. On the other hand, amylase production, which is negligible on the first day, steadily increases as the incubation period proceeds, and reaches its peak value on the fourth day. These observations show that there is some relationship between the production of antibiotic substances on one hand and amylase formation on the other. Probably the secretion of antibiotic substance at an earlier stage serves to prevent invasion by undesirable organisms. In the light of the observations already made by Rao and Murti[6], the lag phase in amylase formation may bear some relation to the development of antibiotic substances. Further work in this direction is in progress.

My thanks are due to Prof. V. Subrahmanyan for his interest and guidance.

Origin of the Radio Frequency Emission and Cosmic Radiation in the Milky Way

Recent measurements by Hey, Parsons and Phillips[1] on the angular distribution of the galactic radio-frequency radiation at 64 Mc./s. and particularly the observations by these authors, by Bolton and Stanley[2,3] and by Ryle and Smith[4] on variable sources of radio-frequency radiation in low and high galactic latitudes strongly suggest a revision of current ideas on the origin of this radiation.

The interpretation of galactic radio-frequency radiation by free-free transitions of electrons in the interstellar gas, as advanced by Reber, Henyey and Keenan[5] and also adopted by myself[6], besides being obviously unable to explain the variable radiations now meets with the following difficulties :

(*a*) The explanation of the intensity and angular distribution at 20–30 Mc./s. requires the assumption of an electron temperature of 100,000–200,000° K., as Townes[7] and the present author[6b] noticed independently. On the other hand, we know that even in planetary nebulæ with central stars of more than a hundred thousand degrees, the temperature of electrons is kept as low as approximately 10,000° by collisions with oxygen. (*b*) The observed 'concentration' of the radiation in galactic latitude is too small, that towards the galactic centre too strong.

Let us now examine the assumption—which hitherto has mostly been rejected—that the galactic radio-frequency radiation originates in some particular type of stars. Comparing the 'radio-isophotes'[1] of the galaxy with the visual ones of Hopmann[8]—taking roughly into account the obscuration by dark nebulæ—we find that an *average* mag. 1 star (visual scale) emits about 2×10^{-23} watts per m.^{2} per c./s. (afterwards simply called a 'unit').

The discrete sources[1,2,3] emitting 6×10^{-23} (Cygnus) to 2×10^{-24} (Hercules) units cannot, so far, be identified with any reasonable objects on Bottlinger's Galactic Atlas; these should therefore be fainter than mag. 6. For them, therefore, a mag. 1 object would emit *more* than 6×10^{-21} to 2×10^{-22} units. On the other hand, the sun (mag. − 27, visual) emits approximately 13×10^{-23} units—taking the 'quiet' radiation with an effective temperature of $1 \cdot 5 \times 10^{6}$ degrees; slight perturbations are sufficient to increase this figure by several powers of ten. Using the first 'standard' figure, we obtain for a mag. 1 star approximately 8×10^{-34} units.

It seems at first quite incredible that the ratio of 64 Mc./s. radiation to visual light should be $2 \cdot 5 \times 10^{10}$ times higher for an average star and probably more than 10^{13} times higher for some of the discrete sources than it is for the sun. In reality, however, there is nothing impossible about the idea that the sun is an extremely weak radio-frequency radiator.

During the great solar eruption of July 25, 1946, according to Lovell and Banwell[9] the radiation on 72 Mc./s. increased temporarily to an effective temperature of 8×10^{11} °K., that is, by a factor of $5 \cdot 3 \times 10^{5}$ compared with our adopted 'normal' value. Considering, moreover, that the area of the eruption observed by Ellison[10] in $H\alpha$ was only 1/800 of the visible hemisphere, and that for a star with a surface temperature of 3,000°, for example, the surface area per unit visual light is about ninety times larger than for the sun, a total extra-factor of 4×10^{10}, or even somewhat more for a star with strong eruption-activity, appears quite possible.

The low galactic concentration of radio-frequency emission[1] indicates that it originates not in the high-temperature *O* and *B* stars showing high concentration towards the galactic plane, but in late-type stars, probably connected with Baade's population II. This hypothesis is favoured by the strong radio-frequency radiation of the galactic nucleus consisting of population II stars[11]. In addition, it should be noted that the spectra of many late-type stars exhibit indication of an 'activity' much superior to that of the sun, that is, strong emissions within the Ca^{+}, H and K absorption lines; broad hydrogen emissions superposed by metallic absorption lines as in solar eruptions[12], etc. Since even large solar eruptions give very little change of visual light, we should not expect necessarily to find great visual light variations in objects emitting a changing radio-frequency radiation.

Some difficulty might be derived from the fact that the frequency distribution of the galactic radiation is somewhat different from that of the sun. However, observations by Allen[13] on the angular distribution of the sunspot-radiation at 200 Mc./s. (derived from Fig. 4, ref. 13) indicate that this is emitted at a radio-optical depth of approximately 4. Quite plausible differences among the absorbing layers of different types of stars thus appear amply sufficient to account for the observed differences of the radio-spectra.

Our hypothesis of the great abundance of stars the radio-frequency emission of which is roughly 10^{11} times higher than that of the sun gains increased interest in connexion with Forbush's[14] and Ehmert's[15] discovery of cosmic radiation emitted by solar flares. For the strong eruption of July 25, 1946, Forbush—measuring two-hourly means—observed an increase of cosmic radiation by 15 per cent. Let us compare now the 64-Mc./s. radiation for this eruption of about 5×10^{-20} (to 5×10^{-19}) units with that of the whole sky. Using the 'isophotes' given by Hey, Parsons and Philips[1], I get an average intensity of roughly 5×10^{-21} units per unit solid angle, or $6 \cdot 3 \times 10^{-20}$ units altogether. Thus the ratio of eruption-radiation to everyday radiation is almost the same for the 64-Mc./s. radio-frequency radiation and for the cosmic radiation primarily consisting of charged particles.

Taking the average over 3·2 years, Ehmert's coincidence-counting indicates a solar contribution of 0·07 per cent to the cosmic radiation, a figure which for various reasons might be increased somewhat. Taking the average radio-frequency radiation of the sun to be ten times this normal, that is, $1 \cdot 3 \times 10^{-21}$ units, this is about 2 per cent of the radiation of all the galaxy. Again, the idea of a general proportionality between cosmic radiation and radio-frequency radiation is confirmed.

Since the cosmic radiation undergoes considerable changes within the uppermost few cm. of mercury pressure of our atmosphere, we must in any case assume that it originates in the tenuous outer parts of some cosmic structures. The hypothesis of its origin in supernovæ would lead us to expect a great increase of cosmic radiation in connexion at least with every galactic supernova. In fact, an eruption like that of Tycho's nova in 1572, which at maximum was about 400,000 times brighter than most extra-galactic supernovæ, should have increased the cosmic radiation so much as to produce great biological effects which could not have been overlooked.

On the other hand, within the frame of our hypothesis, the problem of a sidereal time variation of the cosmic radiation should be investigated more closely. In any event, the magnetic field of the earth and perhaps also cosmic fields of force[16] will smooth out considerably the angular distribution of the primary cosmic radiation coming from the galaxy.

Altogether our central hypothesis that the radio-frequency radiation of the galaxy as well as the cosmic radiation originate in (late type) stars showing eruption-activity like the sun, only roughly on a 10^{11} times larger scale, has much to recommend it. The detailed physical mechanisms for the production of both radiations remain to be investigated; no doubt large-scale magnetic fields changing in vast layers of tenuous ionized gas play an important part (see refs. 17, 18, 19). Applying Faraday's law of induction, it is evident[18] that changing solar magnetic fields can at most produce 10^{9}–10^{10} eV. The observation of energies up to 10^{15} eV. points toward the existence of much larger spots, etc., in stars in agreement with our previous assumptions.

Maintenance of Nocturnal Ionization

THE rate of change of ionization in the F_2 ionospheric layer is considered to follow the equation

$$dn/dt = q(t) - \alpha n^2, \qquad (1)$$

under the assumption that the layer is electrostatically neutral and that the net rate of attachment[1,2] is negligible. In (1), n is the number of electrons/cm.^{3}, α is the coefficient of recombination (cm.^{3}/sec.) and $q(t)$ is Chapman's ionization function[3]. During darkness $q(t) = 0$; whence upon integration equation (1) becomes

$$1/n = \alpha t + C_1. \qquad (2)$$

It is well established that during the absence of solar radiation the decrease in ionic concentration does not follow equation (2) exactly. In an effort to provide a better explanation of the nocturnal concentration of ions in the F_2-region, the following theory was developed.

A diurnal temperature variation is assumed to exist at the height of the F_2-layer such that

$T = T_m$, from 2 hours after sunrise to 2 hours before sunset;
$T = T_m \exp(-2ft)$, from 2 hours before sunset to sunrise;
$T = \varphi(t)$, from sunrise to 2 hours after sunrise. (3)

These assumptions are consistent with the theory of radiative equilibrium put forward by Godfrey and Price[4], and other workers in this field. The constant f may be easily evaluated employing $T = T_0$ at sunrise, and t as the time elapsing between the occurrence of T_m and T_0.

From relationship (3) it is easily ascertained that the corresponding pressure function as evaluated from the hypsometeric equation is given by

$$P = P_m \exp(-2f(g+1)t, \qquad (4)$$

where g is a constant empirically determined. The value P_m is that computed when $T = T_m$.

Obviously, under the assumed nocturnal temperature decrease, an atmospheric contraction occurs at the level of the F-layer. We make the logical assumption that the influx of electrons/cm.^{3} is proportional to the influx of total particles/cm.^{3}.

Now define an 'influx function'

$$s(t) = (n/N)\, dN/dt, \qquad (5)$$

which governs the increase in ionic concentration brought about by atmospheric contractive effects. N is the total number of original particles/cm.^{3}.

Under the above conditions, the equation for the rate of change of ionization during the absence of solar radiation becomes (neglecting meteoritic and other possible ion sources)

$$dn/dt = s(t) - \alpha n^2. \qquad (6)$$

It is further recalled that under conditions of volume recombination such as exist in the ionosphere, it is possible to write[5]

$$\alpha = aT^{1/2} = aT_m^{1/2} \exp(-ft), \qquad (7)$$

where T is the electron temperature (° K.). It is permissible to employ equation (7) if it is assumed that the velocity distribution of the electrons, ions, and other particles follows a Boltzmann distribution, and that all particles are in thermal equilibrium.

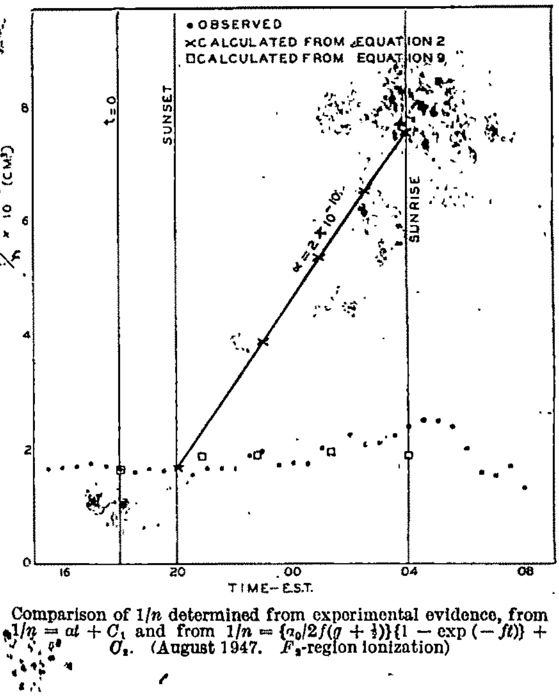
The complete recombination equation during darkness, taking cognizance of the dependence of the recombination coefficient on temperature, thus becomes

$$dn/dt = (n/N)\, dN/dt - \alpha_0 n^2 \exp(-ft), \qquad (8)$$

where $\alpha_0 = aT_m^{1/2}$. The above equation on simple quadrature becomes

$$1/n = \{\alpha_0/2f(g+\tfrac{1}{2})\}\{1 - \exp(-ft)\} + C_2. \qquad (9)$$

The accompanying figure shows $1/n$ versus time (Eastern Standard Time) for one day in August 1947 at Washington, D.C.[6]. The value of n was computed from the familiar expression $n = Kf^2$ for each half-hour interval. Upon the graph is indicated the decrease of electron concentration expected from equation (2), and that anticipated by employing equation (9). It is evident that the rate of change of electron population is very much better described



Comparison of $1/n$ determined from experimental evidence, from $1/n = \alpha t + C_1$ and from $1/n = \{\alpha_0/2f(g+\frac{1}{2})\}\{1 - \exp(-ft)\} + C_2$. (August 1947. F_2-region ionization) by the latter relationship, which contains the influx term, than by the former.

Since the temperature at the height of the E-layer was considered to have a negligible diurnal temperature variation, the relationships derived above degenerate to the conditions usually assumed for the E-ionospheric layer.

Uncertainty Principle

WRITERS appear either to introduce or to illustrate the uncertainty principle by supposing that a fundamental particle such as an electron is viewed through a microscope to determine its position at the same time as measurement is being made of its momentum[1]. The error in the position of the particle is accepted to be δx in the formula for the resolution power of a microscope, namely, $\delta x \sim \lambda/\sin\theta$. This formula is derived in optics from a study of the diffraction of light from two equal disks placed close together and from one disk alone.

Now the diffraction ring patterns of the disks are brought about, according to the quantum theory itself, by the action of quanta in the mass, and each individual quantum merely energizes a particular spot in a pattern. I cannot see that the optics formula, which essentially gives the effect of the mass action, can be applied to the action of an isolated quantum or photon. The appearance of a single photon on a screen cannot furnish any information about the direction from which it came before striking the screen, and even less can it indicate the point from which it emanated. If, as we are told, the wave phenomenon of light is due to mass action of photons, then we require proof that the wave formula can be applied to an individual photon, because we know that the behaviour of a single molecule of a gas is different from the mass behaviour of molecules producing sound in a gas.

A second difficulty is that the optics formula does not so much give a fundamental limit to observation, but rather a formula of convenience. It implies that it is difficult for the unaided eye to differentiate between the two sets of ring patterns, but it makes no claim that no difference exists between the patterns. The analysis admits that the set from one disk alone is circular, whereas that from two disks close together is oval. The formula gives the condition that the inner rings from the two disks change over from dumb-bell shapes which can readily be associated with two disks, to approximately elliptical ovals which cannot. By employing accurate methods for measuring shape and the intensity distributions in the fields, we can proceed considerably beyond the limit represented by the formula. An astronomer, for example, is justified in deducing that a star is a double star if the ring pattern he obtains from it is oval.

Perhaps the quantum theory can put this matter right, but I find the classical arguments so full of gaps that they are far from convincing.

Early Man and Fossil Vertebrates on the Island of Celebes

OUTSIDE Java, which has yielded many important finds of fossil remains from the *Pithecanthropus* group of mankind and an abundance of fossil vertebrates, as well as two distinct palæolithic industries (the Patjitan chopper chopping-tool complex with an intrusion of 7 per cent Acheul hand-axes, and the Sangiran flake industry), palæolithic finds have not hitherto been made in the Indonesian Archipelago.

Prehistorical research on Celebes has now shown, however, that early man inhabited this island in Pleistocene times, since palæolithic tools have been discovered, associated with fossil bones of vertebrates of Asiatic origin. The newly discovered site is situated in the southern part of the island near Tjabenge and is bordered by the Walanae River on one side and by the Great Sinkang depression on the other.

Dr. D. A. Hooijer, of the Rijksmuseum van Natuurlijke Historie at Leyden, has studied the fossil fauna and has distinguished among the small collection five different forms, of which three are extinct: (1) a new genus of a large pig, *Celebochœrus heekereni* Hooijer[1]; (2) a dwarf archidiskodont elephant which is very closely related to the Lower Pleistocene *Archidiskodon planifrons* (F. and C.) from India and China[2]; (3) a large tortoise, *Testudo margæ* Hooijer[3]. The other two fossils are *Anoa depressicornis* (Smith) subsp. and *Babyrousa babyrussa beruensis* Hooijer[4], which are two typical elements from the recent fauna of Celebes, thus proving that those mammals had already evolved in Pleistocene times.

Celebes was, perhaps, never connected with Java (and Borneo), as the islands are separated by the deep Strait of Macassar and the Flores Sea. This is the so-called 'Wallace's Line', which indicates a faunal break between the Indo-Malayan and the Australian fauna (1860). This theory was at first generally accepted by zoologists; but now it is known that 'Wallace's Line', which was geologically well founded, separates a zone with rich animal life from a badly impoverished one, as Ernst Mayr has rightly pointed out. Migration to Celebes took place via land-bridges, which connected this island with the Philippines, Formosa and southern China. The newly discovered palæolithic industry is very closely related to the Sangiran flake industry.

Systematic research in this part of Celebes will no doubt lead to other important finds.

INTERNATIONAL RADIO CONFERENCES

DURING the summer of 1948 there were a number of international meetings in Europe on various aspects of radio research, development and operation. Three of these were held in Stockholm during July, while some of the others took place in Brussels, Copenhagen and London (see *Nature*, **161**, 695; 1948).

The International Scientific Radio Union (U.R.S.I.) held its Eighth General Assembly in Stockholm during July 13–24. Beginning concurrently with this meeting, the Fifth Reunion of the International Consultative Committee on Radiocommunication (C.C.I.R.) was also held in Stockholm. On the termination of the U.R.S.I., a brief meeting of the Joint Commission on Radio-Meteorology was held in the same place. Later, in Brussels, during July 28–30, there was a meeting of the Mixed Commission on the Ionosphere. At all these meetings the subjects discussed included various scientific and technical matters on which international collaboration or agreement is necessary in order to advance our knowledge of radio science and its application to radio communication, broadcasting and navigation. The above meetings were followed by a British Commonwealth Specialist Conference on Radio Research held in London during August 4–6. This formed a very convenient occasion to review the various recommendations made by the international assemblies, and to agree on an appropriate distribution of responsibility, within the Commonwealth, of the British contribution to the international research programme.

Wave-lengths for Broadcasting

Reference has already been made in *Nature* (**162**, 562; 1948) to the European Broadcasting Conference in Copenhagen, where over a period of some ten weeks a new plan was produced for a revised allocation of wave-lengths to broadcasting stations in Europe. The Copenhagen plan, 1948, as it is called, will come into operation on March 15, 1950, when some 340 stations and synchronized networks will be accommodated in 139 channels in the long (frequencies 150–285 kc./s.) and medium (525–1,605 kc./s.) wave portions of the radio spectrum allotted exclusively for broadcasting. Details of the new wave-lengths, with the frequency and power assigned to each station, are given in the *Wireless World* of November 1948.

Resolutions of the U.R.S.I. and C.C.I.R.

Reverting to the two major conferences, which are concerned with scientific research and development, some brief details of the resolutions and recommendations of the U.R.S.I. and C.C.I.R. are given below. The International Scientific Radio Union, the president of which is Sir Edward Appleton, after considering the extension of the radio field, decided to replace the four commissions, into which it was previously organised, by seven commissions. The titles and presidents of these are as follows: (I) Measurements and Standardization, Dr. J. H. Dellinger (U.S.A.); (II) Troposphere and Wave Propagation, Dr. C. R. Burrows (U.S.A.); (III) Ionosphere and Wave Propagation, Sir Edward Appleton (Great Britain); (IV) Terrestrial Atmospherics, Prof. H. Norinder (Sweden); (V) Extra-terrestrial Radio Noise, Dr. D. F. Martyn (Australia); (VI) Waves and Oscillations, Prof. B. van der Pol (Netherlands); (VII) Electronics, Dr. G. Lehmann (France).

The C.C.I.R. conference was held under the presidency of Dr. H. Sterky, director-general of telegraphs in Sweden, and was attended by delegates from more than thirty nations. A large proportion of its work at Stockholm consisted in surveying a number of technical questions put forward by the Atlantic City meeting of the International Telecommunications Union. Only a preliminary examination of these subjects could be carried out in most cases; and at the termination of the meeting, the plenary assembly of the C.C.I.R. set up thirteen international study groups to carry out preparatory surveys and submit reports for the next reunion, which is to take place in 1951. The subjects for study included various aspects of radio transmitters and receivers, wave propagation along the ground and through the lower and upper atmosphere, time signals and standard frequencies, and certain questions relating to broadcasting and television. During the Stockholm meetings, recommendations were made that Prof. B. van der Pol, of the Netherlands, should be appointed director, and Mr. L. W. Hayes, of the British Broadcasting Corporation, vice-director, of the C.C.I.R. Both appointments were to be taken up in January 1949.

Some of the conclusions and resolutions on scientific matters reached by the various conferences are referred to briefly in the following sections.

Radio Standards and Measurements

It was strongly recommended by the U.R.S.I. and the C.C.I.R. that the study of field-strength measurement over the whole frequency spectrum should be continued, and that the interchange of equipment between the various national laboratories should be encouraged. In addition, the U.R.S.I. urged that a study of standard noise sources of various types should be carried out, and that investigations should be made of the various methods of measuring radio-frequency power, particularly at frequencies above a few hundred megacycles per second.

On the question of standard frequency transmissions, the C.C.I.R. stated that there is an urgent need to put into operation additional standard frequency and time stations, perhaps in the United Kingdom and in Australia, to serve the now inadequately served areas of the world. Such stations should operate on the frequencies assigned for the purpose at the Atlantic City Conference in 1947, and it was recommended that an international study group should organise and control experiments to determine the effective service areas and the zones of interference with the existing emissions from Washington (Station *WWV*).

The Commonwealth Conference urged that the plans for the establishment of a standard frequency service in the United Kingdom should be pursued, and that both Australia and South Africa should establish similar services, if possible.

A further recommendation of some interest is that all standard-frequency stations should periodically and simultaneously interrupt their transmissions to permit measurement of natural radio noise, suitable programmes for this purpose to be worked out jointly by the U.R.S.I. and C.C.I.R.

Radio Wave Propagation

The subject of wave propagation was of common interest to all the international bodies, although perhaps with different objects in view; the following recommendations may therefore be taken as being agreed generally by the various organisations concerned.

(*a*) *Propagation through the ionosphere.* In order to assist the study of the characteristics of the ionosphere, and the presentation of the results of ionospheric soundings, a detailed list of symbols and related nomenclature was drawn up and recommended for general adoption. Various details in the technique of carrying out vertical incidence soundings were revised in order to secure uniformity in practice at ionospheric observatories. There was general agreement that the density of ionospheric recording stations over the world should be increased, particularly along the three lines of longitude, 150° E., 20° E. and 70° W.

The Brussels meeting of the Mixed Commission on the Ionosphere was presided over by Sir Edward Appleton, and in the course of its six sessions it surveyed in some detail our present knowledge of the ionosphere as obtained by direct radio exploration, and also by studies of auroras and geomagnetic phenomena. A number of resolutions were drawn up for consideration by the appropriate international scientific unions, with the view of enhancing the correlation of the characteristics of the ionosphere with geophysical and astrophysical phenomena.

At all the conferences there was universal agreement on the need for encouraging theoretical and experimental research on the mode of propagation of radio waves through the ionosphere, involving an increased and more precise knowledge of the absorption in the various regions, which is essential to the success of the forecasting of communication conditions. Particular attention was directed to the need for studying the technique of obtaining warning of disturbed conditions in the ionosphere, and communicating this to the practical user.

(*b*) *Propagation through the troposphere.* There was complete agreement at the Stockholm and London Conferences that it was necessary to proceed as rapidly as possible with the study of the propagation of waves at all frequencies above 30 Mc./s., in order to ensure the best and most efficient use of this end of the radio-frequency spectrum. At the lower end of this range, it is sometimes necessary to take ionospheric conditions into account; but in general at these frequencies, it is the propagation of such waves over the ground and the obstacles on it, and through the lower atmosphere, that is much more important in connexion with the practical applications of very short waves. It was recommended that simultaneous studies of radio-wave propagation and the associated meteorological conditions should be undertaken on as wide a basis as possible, and that the appropriate scientific radio and meteorological organisations should study the relevant characteristics of the troposphere in all parts of the world. In this connexion the need was expressed for improved techniques for measuring the vertical and horizontal gradients of temperature and humidity in the lower atmosphere, and the variations of these gradients with time and place. It was considered that the time is approaching when a suitable standard nomenclature might be drawn up for this subject, together with a uniform method of presenting both the radio and meteorological results.

These general recommendations were confirmed and elaborated by the Stockholm meeting of the Joint Commission on Radio-Meteorology, which held two technical sessions under the presidency of Dr. C. R. Burrows, of Cornell University. It was agreed that this Commission should direct its attention, as opportunity arose, to the theoretical and experimental determination of those properties of the lower atmosphere which affect radio propagation. These were deemed to include the study of storm detection by radar, and the location of sources of atmospherics by radio methods, as well as the actual transmission of radio-waves for communication or other purposes.

(*c*) *Long-wave propagation.* Following the lead given by the international bodies, the London Conference recommended that those Commonwealth countries in a position to do so should carry out a study of long waves propagated along the ground and through the ionosphere, and should seek the co-operation of other members of the Commonwealth when necessary. Partly in this connexion, it was considered important to increase our knowledge of the electrical constants of the ground, and all Commonwealth countries were urged to collect all appropriate information on this subject and arrange for its adequate distribution; and the United Kingdom was asked to prepare a survey of existing knowledge of the electrical constants of the ground at radio frequencies.

Radio Noise

In addition to the remarks already made above on this subject, the C.C.I.R. considered that atmospheric radio noise imposes one of the most important limitations on communications, and that therefore the study of such noise should be pursued on as wide a basis as possible. The conclusions agreed with those of the other bodies in recommending that meteorological studies should be undertaken to provide a knowledge of the distribution and nature of thunderstorms and the atmospherics originating from them. Investigations of the propagation of atmospheric disturbances and of the wave-forms and magnitude of the radio noise should be made in association with measurements of the direction of arrival at the receiver. Attention should also be given to the measurement of noise characteristics and their effects on receiving equipment in the frequency-range 10 kc./s. to 30 Mc./s., with particular reference to the range 10–300 kc./s.

The Commonwealth Conference endorsed the above recommendations and agreed to support the United Kingdom in the continuation and extension of a world survey of atmospheric noise-level by a subjective measuring method until the technique can be improved. It was further suggested that, in the interests of saving man-power and of ensuring that the quality of the data be as good as possible, particular consideration should be given by the United Kingdom to restricting the time schedule of such observations to the minimum necessary to obtain an adequate representative sample.

All meetings agreed that the work at present being conducted on solar and cosmic noise in various countries should continue on the existing lines.

Conclusion

The above notes are intended as only a general survey of the main conclusions of the conferences, and a more detailed consideration of the various recommendations must await the publication of the proceedings of the meetings in the usual manner. Apart from the actual committee work leading to these results, the various conferences provided the usual informal opportunities for meeting contemporary workers in other countries. The meetings in Sweden also enabled delegates to visit certain research and manufacturing organisations in Stockholm and Gothenburg. R. L. SMITH-ROSE

LARGE-SCALE VERTICAL MOTION IN THE ATMOSPHERE

AT a meeting of the Royal Meteorological Society on February 16, the subject for discussion was large-scale vertical atmospheric motion. In opening, Mr. J. K. Bannon stressed the importance of the rising and sinking of large masses of air in atmospheric dynamics and explained the relatively small attention given to vertical motion by meteorologists by the fact that so far it has been impossible to measure directly the vertical velocities, which can only be inferred, and that with difficulty. He went on to describe a method of estimating up-currents from the rate of rainfall[1], depending on the approximate equality of the rate of release of precipitation from a mass of rising air and the rate at which the saturation vapour content of the same air decreases as the temperature falls due to adiabatic expansion (that is, neglecting the changing water content of the cloud particles, which is small except in convection clouds). This method can be applied in cases of steady rising currents over a wide area (thirty miles square or more), and examples of results obtained from rainfall records in the Hebrides show that up-currents in the lower and middle troposphere are of the order of 10–20 cm./sec. in typical disturbances of the North Atlantic.

Mr. J. S. Sawyer then gave a brief description of two other methods of deducing vertical atmospheric movement. The first, that of Graham[2], requires a network of upper air observations of temperature and wind at regular time intervals. The horizontal motion between consecutive times of upper air observations being known, temperature changes unexplained by horizontal movement are assumed to be due to changes in height, and to take place adiabatically; and hence the vertical motion in the period may be inferred. The method is quick and may be used by the weather forecaster; the results are consistent with other phenomena such as rain (up currents). The second method, which Mr. Sawyer has applied to several cases in the neighbourhood of the British Isles, depends on the relation between vertical motion and the divergence of the horizontal wind field (the equation of continuity), and between the divergence of the horizontal wind field and the rate of change of the vertical component of vorticity (the vorticity equation). Several approximations must be made, but even so the technique is rather laborious and the method is only suited to research. Notwithstanding the approximations, the results obtained agree qualitatively with expectations, up-currents being deduced over rain areas and down-currents over anticyclones; Graham's method gave comparable results. As emphasized later in the discussion by Dr. R. C. Sutcliffe, this vorticity method requires only knowledge of the pressure field—at more than one level, of course—and can be employed when wind observations are lacking.

Prof. P. A. Sheppard then gave a preliminary account of work being carried out under him in the Department of Meteorology of the Imperial College of Science and Technology by Mr. H. A. G. van Ufford and others. The eight radar wind-finding stations in the British Isles may be grouped to form seven triangles with sides of the order of 200–300 miles in length. The wind observations at the corners of these triangles (specially supplied by the Director, Meteorological Office, to the nearest degree in direction and the nearest knot in speed) were used to evaluate the horizontal divergence over each triangle, at 100 mb. intervals, between pressure-levels of 900 mb. and 200 mb., that is, approximately between 3,000 and 40,000 ft.; by the equation of continuity the vertical motion at each level was deduced from the horizontal divergence. The months December 1947–February 1948, inclusive, were investigated, and the large amount of data so obtained is still being analysed.

A few examples of results obtained were given. The weather of December 1947 was mainly anticyclonic over southern England, that of January 1948 very disturbed and cyclonic; frequency curves of the distribution of ρw (where ρ is air density, w is vertical velocity) for both the lower and upper troposphere reflect this, showing a preponderance of down-currents in the south of the British Isles in the first month; in the January, both in the north and the south of the country, almost equal numbers of up and down currents occurred, and larger vertical velocities were more frequent. Prof. Sheppard also demonstrated curves showing the distribution with height of the mean up and down velocities for January 1948 over central England. When there was general ascent below 500 mb. the maximum of just over 7 cm./sec. occurred between 600 and 500 mb., that is, about 16,000 ft.; with general subsidence in the troposphere, the maximum was between 6 and 7 cm./sec. and occurred between 500 and 400 mb. (about 20,000 ft.). It is noteworthy, he said, that in both cases the mean up and down currents, respectively, at tropopause-level are about 4 cm./sec. As well as the statistical results, which Prof. Sheppard stressed were the most important and significant outcome of the investigation, the distribution of vertical velocity was demonstrated for a few individual occasions, agreeing well with the general features of the weather (rainfall, development of ridges of high pressure, etc.). Velocities, both up and down, of up to 30–40 cm./sec. were deduced even in the lower stratosphere, though 10–20 cm./sec. were more usual maxima.

Mr. M. K. Miles said that, in using Graham's simple method, it is necessary to remember its limitations; as the author admits, it does not always lead to one definite value of vertical motion, and also the deduced velocity is an average over a considerable time, usually 6–12 hours. A comparison with Bannon's method, which tends to under-estimate the up current, and with a direct evaluation from horizontal wind observations, in one particular case, showed that Graham's method considerably under-estimates the vertical velocity.

Dr. R. C. Sutcliffe was enthusiastic of the results obtained so far by Prof. Sheppard. The network of upper air observing stations in the British Isles is the closest in the world, and this region should be used to determine the basic facts of the structure and working of typical weather situations. Atmospheric models, so determined, may then be applied to similar phenomena in other parts of the world where upper air information is scanty or lacking. Prof. Sheppard's investigation is an example of the use to which the British Isles observations may be put, to the great benefit of meteorology generally. Dr. Sutcliffe also pointed out that the horizontal scale of these vertical currents deduced by Prof. Sheppard is implicit in the dimensions of the triangles of observations used.

In reply to questions from Mr. C. S. Durst, Prof. Sheppard said that he had found no individual cases giving ridiculous values for the vertical velocities; since the radar wind observations are averages over depths of about 3,000 ft., such small variations in the wind as Richardson[3] feared would preclude any attempt at a numerical analysis of the wind field of a weather situation are probably eliminated. The time required to analyse each wind-finding ascent for all the various levels is about half an hour, using graphical methods. This indicates the large amount of work involved in producing the basic data for his investigation.

In concluding the discussion, the president, Sir Robert Watson-Watt, said that the results described showed exciting progress; as that most famous English meteorologist, Sir Napier Shaw, used to emphasize, measurements are as essential in meteorology as in every other branch of science.

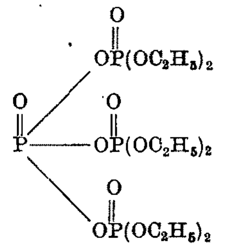
INSECTICIDAL PROPERTIES OF CERTAIN ORGANO-PHOSPHORUS COMPOUNDS

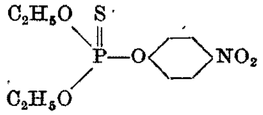
THE success of D.D.T. and benzene hexachloride insecticides has already shown the important part that synthetic chemicals can play in agriculture. Interest is therefore being shown in the organo-phosphorus group of insecticides, especially as certain of these compounds show high contact-activity and others are capable of rendering the plant systemically insecticidal. As these compounds have not yet been available in sufficient amounts for wide-scale investigations, and as little has been published on the subject, there is a considerable demand for accurate information. A meeting of the Association of Applied Biologists on November 5 sought to adjust this state of affairs by bringing together workers qualified to speak on various aspects of the subject.

Dr. H. Martin, of Long Ashton Research Station, introduced the proceedings. He referred to the classical work of Michaelis (1890–1915) on the chemistry of the organic compounds of phosphorus, and mentioned that Nylen[1] had described the tetraethyl ester of pyrophosphoric acid but had overlooked its toxicity towards insects. The discovery of, and information on, the insecticidal properties of these compounds was due almost entirely to Schrader[2]. He had shown that tetraethyl pyrophosphate is highly toxic to aphides, but had not carried forward his discovery to the manufacturing scale, as the substance rapidly lost its activity in contact with water. Instead, Schrader had investigated the reaction between phosphoryl chloride and triethyl phosphate and had obtained a product known as hexaethyl tetraphosphate (I), which he considered had the following structure:



(I)

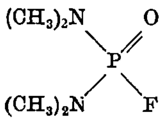
This substance was shown to be as toxic to aphides as nicotine and to have sufficient water-stability to be of practical value; consequently, its manufacture was commenced in Germany in 1944. Dr. Martin mentioned that chemical evidence had recently been produced that hexaethyl tetraphosphate is probably a mixture of alkyl polyphosphates; but investigations at Long Ashton on the toxicity of samples prepared by different processes had revealed no differences. However, it is not sufficiently stable for use with alkaline spray material such as lime sulphur or for incorporation in dusts, consequently its usefulness to agriculture is limited. Schrader found that the thiopyrophosphoric esters were more stable to hydrolysis than the pyrophosphoric esters, yet retained their pronounced insecticidal action. In 1945 a series of thiophosphoric acid derivatives was investigated, with the result that the highly potent insecticide, diethyl-*p*-nitrophenyl thiophosphate *E*.605 (II), was discovered.



(II)

E.605 was a marked improvement on hexaethyl tetraphosphate. It is more toxic to many species of aphides than nicotine, giving a complete kill at 0·005 per cent (Schrader), and is sufficiently resistant to hydrolysis to be used with lime sulphur or as a dust. It is also ovicidal, being about as toxic to *Aphis pomi* eggs as 3 : 5-dinitro-*o*-cresol. Claims had been made that *E*.605 was toxic to a wide range of insects. Schrader found that diethyl-*p*-nitrophenyl phosphate (*E*.600) was also highly insecticidal, but had not gone further with this compound on account of its toxicity to mammals.

Dr. Martin then referred to the discovery of the systemic insecticides by Schrader and Kükenthal[3]. Apparently these workers had included a soil-watering test in their routine examination for insecticidal properties, and had found that certain organic compounds could be absorbed by plants, which thereby became toxic to insects placed on them. Few of the systemic insecticides described by Schrader are available in Great Britain, but three have been examined at Long Ashton:

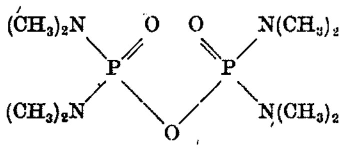


(III)

Bis-(dimethylamino)fluoro-phosphine oxide

$CH_2(OCH_2CH_2F)_2$ (IV)

Bis-(2-fluoroethoxy)methane



(V)

Pyrophosphoryl tetrakis dimethylamide

Dr. Martin considered that the systemic insecticides would prove of value in the investigation of translocation in plants, but he deprecated their practical use for insect control before it is known whether or not they are toxic to mammals or give rise to toxic products in the plant.

Dr. H. E. Coates discussed points of chemical interest concerning the phosphorus insecticides, particularly methods of synthesis and questions of chemical constitution. He said that hexaethyl tetraphosphate is a mixture of linear polyphosphoric esters, hexaethyl tetraphosphate, pentaethyl triphosphate, tetraethyl pyrophosphate and unreacted triethyl phosphate, together with a small amount of acidic by-product. The branched structure (I) suggested by Schrader is incorrect because only a small amount of *ortho*-phosphoric acid is obtained on hydrolysis, whereas the branched formula should give one molecule of *ortho*-phosphoric acid per molecule of the substance. The explanation of linear ester formation is that phosphoryl chloride and triethyl phosphate disproportionate on heating to give a mixture of diethyl chlorophosphonate and ethyl dichlorophosphonite, which then reacts with more triethyl phosphate to give the linear esters. Two methods for the preparation of tetraethyl pyrophosphate were given; the first, of academic interest only, uses silver pyrophosphate and ethyl iodide, but the second, from diethyl chlorophosphonate and triethyl phosphate, is applicable to large-scale production. *E*.605 can be prepared by allowing thiophosphonyl chloride to react with alcoholic sodium ethoxide, the resulting diethyl chlorothiophosphonate being heated with sodium *p*-nitrophenate in chlorobenzene. In the synthesis of bis-(dimethylamino)fluorophosphine oxide, it was shown to be advantageous to cause one molecule of phosphoryl chloride to react with four molecules of dimethylamine to give bis-(dimethylamino)phosphoryl chloride $[(CH_3)_2N]_2POCl$; this gave the desired end-product on reaction with sodium fluoride. Reference was made to a recent colorimetric method[3] for the estimation of *E*.605.

Mr. S. H. Bennett described preliminary experiments with systemic insecticides, referring to certain organo-phosphorus compounds, and to bis-(2-fluoroethoxy)methane, which had been investigated by Schrader, and also to sodium selenate, the systemic properties of which are more generally known. Schrader's findings had first been confirmed at Long Ashton when groundsel plants watered with a 1 per cent solution of bis-(2-fluoroethoxy)methane were shown to be highly poisonous to fully grown larvæ of the cinnabar moth (*Callimorpha jacobææ*). Similar results were obtained using tick bean plants inoculated with bean aphis (*Aphis fabæ*); infestations occurred only on untreated plants. It was found that bis-(dimethylamino)fluorophosphine oxide and bis-(2-fluoroethoxy)methane had powerful systemic properties, but pyrophosphoryl tetrakis dimethylamide was only weakly systemic. These compounds act as fumigants as well as contact poisons; but tests of the former activity failed at first because of the difficulty of separating the fumigant effect of the material in the leaf from that in the soil. This difficulty was overcome by rooting willow plants in water culture, transferring to the insecticide solution and returning to the water culture again when sufficient material had been absorbed, after which it was possible, by assuming uniform distribution of insecticide throughout the plant tissue, to calculate the amount present in a leaf. The fumigant effect was then tested by placing brassy willow beetles (*Phyllodecta vitellinæ*) on muslin with the plant material below and enclosing the whole in a glass vessel. In these circumstances it was found that the fumigant activity of the insecticide in the plant tissue was a hundred times as great as might have been expected from comparable experiments with aqueous solutions. Further experimental work is desirable to explain this effect, which may be the result of differences in the partial pressure of the fumigant in the two systems.

In further experiments, *Calandra granaria* were fed on grain from plants which had been watered with solutions of bis-(2-fluoroethoxy)methane or sodium selenate. While neither compounds caused the grain to become directly toxic to the weevil, infestation did not build up in the selenate-treated wheat, and it appeared that the reproductive powers of the insect had been affected. Referring to the phytotoxicity of these compounds, Mr. Bennett mentioned that bis-(dimethylamino)fluorophosphine oxide is the most toxic to plants growing in soil, but in water culture pyrophosphoryl tetrakis dimethylamide has caused serious plant damage.

In the general discussion that followed, Dr. J. K. Eaton referred to the ovicidal properties of *E*.605 and related compounds. He said that, of the twenty-seven substances examined at East Malling, only *E*.605 and *E*.600 (diethyl-*p*-nitrophenyl phosphate) showed appreciable toxicity to winter moth eggs (*Operophtera brumata*). The eggs of the green apple aphis (*Aphis pomi*) were more susceptible to the action of these organo-phosphorus esters, *E*.600 and di*iso*propyl-*p*-nitrophenyl phosphate giving complete kill at 0·005 per cent. The results indicated that toxicity to *Aphis pomi* eggs is associated with the incorporation into the phosphoric or thiophosphoric acid molecule of two alkyl groups and an aryl group. Toxicity is increased by the introduction of electron-attracting groups in the *para* position of the aryl substitutent. Preliminary field trials for the control of certain species of aphides using *E*.605 and hexaethyl tetraphosphate had been carried out. The results showed that both give control equal to or better than nicotine at the same concentration; *E*.605 is generally the superior. No phytotoxic effects had been noted.

Mr. R. S. Pitcher said that a high kill of the raspberry cane midge (*Thomasiniana theobaldi*) had been obtained under conditions in which *E*.605 appeared to exert an ovicidal effect at a distance. Dr. Martin replied that there was little evidence that *E*.605 had systemic properties, and he considered that the action could be explained as a fumigant effect. Answering a question concerning the use of systemic insecticides marked with radiophosphorus for following the movement of these compounds in plants, Dr. B. A. Kilby said that work had just started at the University of Leeds on the synthesis of such compounds. The most convenient synthesis used phosphoryl chloride as the starting material[1]; but radiophosphorus is most readily available as inorganic phosphate, and the conversion of this to phosphoryl chloride is not easy. The difficulty might be overcome by the discovery of a suitable exchange reaction or by a supply of radiophosphorus in a more convenient form.

Dr. R. A. E. Galley urged that the nomenclature of the organo-phosphorus compounds should be standardized and favoured the introduction of trivial names for the better known phosphorus insecticides.

'MECHANISM' OF *PHYTOPHTHORA*-RESISTANCE OF POTATOES

By K. O. MÜLLER and LOTHAR BEHR*

USING as a basis the American 'native forms' of the tuber-bearing species of Solanaceæ, German breeders during the last two decades have developed potato varieties with both leaves and tubers resistant to most of the known races of *Phytophthora infestans*. It is true that the origin and initial constitution of the material which was used for the breeding of these varieties is only imperfectly known; but we know that its refractory behaviour towards the *Phytophthora* fungus is associated with a gene *R* which is not found in any European variety of the old-fashioned type. Furthermore, according to K. O. Müller, this resistance gene has several associated alleles and is inherited independently of other economically important characters, such as yield capacity, time of maturity, and the like. Therefore it did not take very long to combine the *Phytophthora* resistance of these '*W* varieties' with the high yielding-capacity and other inherent qualities of the European cultivated potato. The first German commercial varieties resistant to *P. infestans* which appeared on the market were Erika (1941), Robusta (1941), Fruehnudel (1941), and Aquila (1942). There are at present in Germany ten new registered potato varieties, all of which possess this resistance gene.

Investigation into the mode of action of this gene, particularly as regards the tubers, led to the conclusion that the alleles present in the *W* varieties are not responsible for the resistant condition itself, but induce only a genetic predisposition of the tissues to 'acquire' a local immunity from infection when they come into contact with the hyphæ of parabiontic races of *P. infestans* (that is, those strains which kill the cells quickly, thereby arresting the further growth of the hyphæ). From the physiological point of view, whether or not a variety is resistant is not decided until the parasite has penetrated into the host tissues. Comparative investigations into the reactions of susceptible and resistant genotypes revealed that in both the host cell is destroyed after coming into contact with the protoplasm of the parasite. Judging by the morphological and physiological changes the final effect is the same—the cell collapses and loses its ability to serve the parasite as a host. But the rapidity with which this final effect is achieved differs in susceptible and resistant genotypes. While the cells of the former live relatively long —six to fourteen days at 19–21° C.—those of the latter die after one or two days, the process being too rapid for fructification of the fungus to occur; moreover, further penetration by the hyphæ is made impossible by the rapid reaction of the host tissue, which in the course of this reaction also loses its ability to serve as a host to eusymbiontic fungus strains (that is, strains which can invade the host tissue without killing it quickly). Other pathogenic micro-organisms, too, are unable to use such 'immunized' tissues as nutritive substrates. The reaction is therefore unspecific (K. O. Müller and H. Boerger).

Cytological-physiological investigations by K. O. Müller, G. Meyer and M. Klinkowski in 1938 showed that it is possible to distinguish in this 'defence-necrosis' at least five successive stages, the last two being characterized by cell collapse and by a heavy infiltration of the cell-walls and cytoplasm with phlobaphene-like compounds, which appear to arise, according to Meyer (1939), through polymerization of tannic substances. These can be demonstrated by the usual tannin reagents after infection in host cells which are still alive.

This close relation between the degree of resistance and the rapidity with which necrosis is brought about was demonstrated in extensive breeding material, consisting partly of previously unselected *F*2 families of crosses between 'resistants' and 'susceptibles'. It was also shown that the two extremes, 'highly susceptible' (the parasite penetrating uniformly through the entire tuber and fructifying luxuriantly) and 'highly resistant' (the parasite penetrating only a few cell-layers of the parenchyma of the tuber and then ceasing to grow without fructifying), are connected by at least two genotypically conditioned intermediate types. These are characterized by an intermediate reaction-rate and—in agreement with what has just been said—their tubers are penetrated to a considerable depth by the parasite (K. O. Müller).

Other investigations led to the conclusion that the 'defence necrosis' is induced by substances secreted by the parasite into the host tissue. Accordingly, the specific behaviour of the resistant genotypes would appear to depend on a specific sensitivity of the protoplasm, controlled by gene *R*, so that the highest reaction-rate would be associated with the greatest degree of resistance. Because the susceptible genotypes also react to these substances, there appears to be no fundamental, but only a graduated, difference between 'resistants' and 'susceptibles', and we conclude (paradoxical though it may appear at first) that the greater the sensitivity of the cells to the metabolic products of the parasite, the greater the resistance of the tuber. Further, the resistance gene *R* is not a factor *sui generis*; it only accelerates a reaction which the susceptible genotypes are also capable of producing. There is, however, a further conclusion. In the course of the reaction the host tissue loses the ability to serve as a nutrient substrate for the fungus. As not only *P. infestans*, but also other micro-organisms which can thrive on a wide range of organic matter (*Rhizopus nigricans*, *Aspergillus niger*, and others), are not able to exist in the necrotic, transformed tissue, the necrosis of the affected tissues must be accompanied by the formation or activation of a principle ('phytoalexin') which exercises a retarding influence on the penetrating parasite. In these circumstances necrosis would depend less on the absolute reaction-rate and more on the relation between the hyphal growth-rate (Cp) and the rapidity with which the principle forms (Cw). Hence with increasing $Cp : Cw$ values the resistance would decrease, while with decreasing values it would increase.

---

* Formerly at the Biologische Reichsanstalt für Land- und Forstwirtschaft, Berlin, now at the National Institute of Agricultural Botany, Cambridge, and Quedlinburg, respectively.

From experiments in which the influence of temperature on the reaction in various genotypes was examined, valuable insight was obtained into the dynamics of the defence mechanism described above (K. O. Müller and R. Griesinger). At low temperatures (5–10° C.) the immunological behaviour of the susceptible genotypes strongly resembled that of the resistant ones. But on the other hand, no decrease in the capacity for resistance in the resistant genotypes was induced. This, however, was achieved in another way, and for this K. O. Müller and L. Behr started from the following hypothesis. If it were possible in the resistant genotypes to retard the necrosis of the tissues affected by the fungus by some kind of chemical or physical treatment of the tubers, the development of the fungus would be promoted simultaneously. The parasite would be able to penetrate farther into the tissues than in the untreated tubers, and at the same time would also fructify.

The experience of other workers (Salmon, Stakman, Bolle, Gassner and Hassebrauck), who have studied the effect of narcotics on the immunological behaviour of plants against fungal parasites, suggested the materials to use for such experiments. The tubers of resistant and susceptible genotypes were treated with methyl, ethyl, propyl, butyl, *iso*propyl, and *iso*butyl alcohol (water–alcohol mixtures), and were inoculated *after* treatment. Germination tests with sporangia of *P. infestans* in alcohol–water mixtures showed that the concentrations used did not check the development of the parasite. The results were as anticipated. The treatment of the tubers with the alcohols above mentioned prolonged considerably the life of the cells which had come into contact with the parabiontic strain of *P. infestans* (retardation of cell collapse, inhibition of phlobaphene formation). At the same time—and this is most important—a material increase in the development of the fungus followed, which in many cases went so far that the parasite developed thick aerial mycelium (with sporangia), even in the highly resistant types.

The accompanying table shows the effect of ethyl alcohol on the immunological behaviour of a highly resistant *W* variety.

That the tubers were *in toto* still alive after the alcohol treatment was shown by the ability of parenchyma cells to become plasmolysed and by the fact that non-inoculated tubers, treated with a 3–5 per cent alcohol–water mixture, could be stored for weeks at room temperature and high air humidity without showing any rotting symptoms caused by facultative parasites.

A comparison of the effects of the four normal alcohols showed that a close correlation exists between the length of the carbon chains and their effect in reducing resistance. Richardson's 'law of homologous series' has thus been confirmed. Furthermore, *iso*propyl and *iso*butyl alcohol were considerably less effective than the normal alcohols. This result, too, agrees with the findings of previous workers, who maintained that the greater the branching of the carbon chains, the less the narcotic effect.

Effect of ethyl alcohol on the immunological behaviour of the *W* variety *BRA* 23/31

Concentration of alcohol (% volume)	Reaction of the host			Development of the parasite	
	Necrotic changes immediately beneath the site of inoculation		Phlobaphene-formation within the tuber	Aerial mycelium (sporangia)	Within the tuber
	after 48 hours	after 120 hours	after 120 hours	after 120 hours	after 120 hours
0 (Control)	very strong	very strong	very strong, distinctly limited (2–3 cell-layers)	none	no mycelium outside the necrotic tissues
3	weak	strong	weak, diffuse, up to a depth of about 10 mm.	thin	parasite penetrated up to about 35 cell-layers
5	weak	strong	,,	thin	,,
10	very weak	very strong	very weak (greatly variable in extent)	thick	penetration up to about 15 cell-layers
12	very weak	very strong	extremely weak, diffuse	very thin	penetration up to about 7 cell-layers

The results of these experiments with narcotics have thus confirmed the original theory developed on a genetic basis: the greater the rapidity with which the host cells in contact with the fungus react to the metabolic products excreted by the fungus, the greater the resistance of the plant. The results also suggested a satisfying physiological explanation of the effects of narcotics in decreasing resistance, noted already by previous workers on other organisms, though differently interpreted. Details cannot be given without exceeding the scope of this short article, but our interpretation appears to have the advantage of explaining satisfactorily many effects, with only one premise to be recognized, namely, the greater the reaction-rate, the greater the resistance.

The effect of chloroform (applied as a vapour) has also been tested, and the result agreed with the above findings. This leads to the conclusion that the action of narcotics on the 'resistance mechanism' is an effect connected with the primarily unspecific changes in the physico-chemical structure of the host cell. As other observations point to the fact that the necrobiosis is connected with the respiratory metabolism of the host cell, it can be assumed that it is this metabolism which the narcotics affect first. This would also hinder the course of the defence necrosis and simultaneously postpone the material changes in the host cell, which we must consider to be the direct physiological cause of the 'defence' against the parasite.

Whether or not this attempted explanation conforms with the facts, we can deduce from the results that the necrobiosis of host tissue, induced by a parabiontic strain of *P. infestans*, is essentially an active response of the affected cells, very probably connected with an increased release of energy. If the defence necrosis of the resistant genotypes induced by fungal contact were the same as a passive dying, such as we can observe, for example, after the effects of supramaximal or inframinimal temperatures, it would appear incomprehensible why just those substances, which in our experience had only a paralysing effect on cell activity, should increase the longevity of infected cells.

SEISMOLOGY IN BRITAIN

A VERY wide range of activity in the fields of pure and applied seismology by British seismologists is referred to in the recently published fifty-third report of the Committee on Seismological Investigations of the British Association for the Advancement of Science.

The work of the International Seismological Summary is carried out by a staff of three, headed by Mr. J. S. Hughes. Through the courtesy of the director of the Meteorological Office it is housed in two huts at Kew Observatory. The bound volumes for 1936 have been issued, as also have more recent quarterly parts. Manuscript for 1937 is compiled. The past year has seen the change-over from the use of normal geographic co-ordinates for the positions of observing stations as a basis for the estimate of travel times to that of geocentric direction-cosines. Such a change means that no distances, calculated for epicentres used before 1937, can be used for preliminary epicentres. The slowing up of the work, now that the system is well in hand, is thought, however, to be inappreciable. Prof. H. Jeffreys (director) and Mr. J. S. Hughes now wish to know what readings they may expect to receive from observatories for the period after the outbreak of hostilities in 1939.

There have been few British earthquakes recently. The earthquake of May 28, 1948, at 17h. 02½m., G.M.T., was felt over a considerable region of Norfolk, Suffolk and Cambridgeshire, but was accompanied by no appreciable damage. It was recorded by the Kew seismographs, both short-period and Galitzin, *Pg* occurring at 17h. 02m. 53s. G.M.T. and *Sg* 14 sec. later; the distance from Kew was therefore about 120 km. Dr. A. T. Dollar, of the University of Glasgow, has resumed the collection of macroseismic data concerning British earthquakes, and it is hoped to publish his collected observations on the small earthquakes of April 2, 1948, at Bethesda, Carnarvonshire, and May 31, 1948, at Ullapool, Ross-shire, together with later observations in 1949.

Phase	Velocity	Starting time	Thickness	Standard deviation of one observation
Sedimentary *P* wave	1·6 – 5·4 km./sec.	0	9·01 ± 1 km.	—
Pg (Near stations)	6·06 ± 0·09	2·8 ± 0·27	17·4 ± 2 km.	0·16 sec. on regional means
Pg (Distant stations)	4·9 – 5·5	—	—	3 sec. for 1 layer. 0·50 and 0·86 for 2 layers
Pn	8·18 ± 0·014	7·37 ± 0·1	—	0·19 sec.
Sn	4·36 ± 0·06	2·8 ± 1·3	—	0·43 sec.
R	3·05 ± 0·1	4·6 ± 6	—	3·6 sec.

Two of the Committee's seismographs were removed from the University Observatory, Oxford, to Down House, Downe, Kent, in 1937, and were put in the care of Dr. O. J. R. Howarth. They were assembled by Miss E. F. Bellamy and later calibrated by Mr. J. S. Hughes and Mr. E. N. Lawrence. Dr. Howarth has since been comparing the seismograms which he has obtained with the readings from the seismograms obtained at the observatories at Kew and Durham, and also with the preliminary epicentres on the cards issued by the United States Coast and Geodetic Survey; he has also sent observations on microseisms to Dr. G. E. R. Deacon at the Admiralty Research Laboratory. In addition, the Committee has Milne–Shaw seismographs at Edinburgh (recording suspended), Cape Town, Perth (Western Australia) and Suva (Fiji), and a Jagger shock recorder at Comrie, Perthshire.

The seismological work of the Department of Geodesy and Geophysics at the University of Cambridge has included Prof. E. R. Lapwood's theoretical investigation of the diffraction effects at the surface of a semi-infinite homogeneous elastic medium after a pulse has been emitted by a buried line source. Prof. Lapwood has shown that at distances large compared with the depth of the source, the disturbance at the time of arrival of the direct *S*-pulse differs from that at the time of arrival of the *P*-pulse in being smudged or blunted. Some seismic work at sea has been done; microseisms with frequencies greater than 8 cycles per sec. have been investigated and are thought to be man-made; and short-range explosion seismology has been done in the Lake District and in Wales. Mr. P. L. Willmore has designed a moving-coil seismograph with a nearly constant response to ground velocities of frequency 2–25 cycles per sec., and a maximum sensitivity of 5,000 cm. per cm. per sec. Mr. M. N. Hill has designed a long-period inductance-bridge seismograph. Mr. Willmore spent several months in Germany, arranging for seismological observations to be made on the tremors from the explosion on Heligoland of nearly 4,000 tons of ammunition on April 18, 1947. Observations were made by portable seismographs in Germany, chiefly from the Geophysical Institutes at Göttingen and Celle, in Holland and in Denmark, and by two ships in the North Sea. The tremors were also recorded by observatory seismographs in Belgium, France, England, Czechoslovakia and Switzerland. Travel times were observed at distances of 50–1,000 km. from Heligoland; these were supplemented by the observations up to 50 km. of the explosion of about 400 tons of explosive near Soltau in the autumn of 1946. The characteristics of the artificial earthquake wave phases are given in the table, which also includes figures for the thicknesses of the assumed layers.

R appears to be a wave, according to Willmore, which was propagated through the ultrabasic layer, after suffering reflexion from the surface at one point in its path. Prof. C. Charlier is of the opinion that this observed phase was propagated through a separate layer in the earth. Calculations from the measurement of seismograms give a value of 10^{17} ergs for the energy transformed into earthquake waves by the whole explosion. Measurements of the crater show that $1 \cdot 5 \times 10^{18}$ ergs were expended in moving the rock above the charge, while the total thermal energy of the explosive was $1 \cdot 3 \times 10^{20}$ ergs.

Dr. G. E. R. Deacon reports that work at the Admiralty Research Laboratory seems to throw some light on the origin of microseisms. It has been shown that pressure fluctuations due to sea-waves likely to be responsible for microseisms occur when there is interference between sea-wave groups of the same frequency travelling in opposite directions. This interference may arise in the neighbourhood of a fast-moving depression over the sea, or in a coastal region where energy is being reflected from the shore. The theory suggests a definite two to one relationship between the periods of the sea-waves and microseisms, which has been confirmed by observations. Further, by submitting simultaneous records of waves and microseisms to frequency analysis, it has been thought safe to conclude that a depression moving rapidly over deep water north of the Azores caused microseisms at Kew. Microseisms on Kew seismograms can be detected some thirty hours before the swell from a distant storm reaches the coast.

ERNEST TILLOTSON

MAGNETIC AMPLIFIERS

THE thermionic valve amplifier is so universal in its application that even the existence of other means of amplifying tends to be overlooked. Two papers read recently before the Institution of Electrical Engineers record developments in magnetic amplifiers, and indicate the field of application within which such amplifiers possess advantages. These papers, "Magnetic Amplifiers", by A. G. Milnes, and "A Theoretical and Experimental Study of the Series-Connected Magnetic Amplifier", by H. M. Gale and P. D. Atkinson, were presented on December 2, 1948.

Essentially the principle of the magnetic amplifier is that of controlling the current in an A.C. circuit by varying, by means of an auxiliary D.C. circuit, the impedance of an iron-cored reactor in series with the load. The D.C. circuit thus effects its control by producing magnetic saturation of the reactor core. This principle has been known and has been applied for many years, indeed since the period of the First World War; but it was not until high-permeability nickel–iron alloys and metal rectifiers became available that rapid development of the magnetic amplifier for a wide range of applications took place.

The basic circuit arrangements of magnetic amplifiers have now assumed fairly well established forms, and the present papers give a systematic theoretical treatment and design procedure for the standard circuits. As a rule the magnetic amplifier operates as a D.C. amplifier in the sense that the input or controlling current is a small direct current, and the output is again a direct current produced by the rectification of the alternating current passed by two reactors, the reactance of which is controlled by the input. A simple, single-stage magnetic amplifier employing high-permeability cores might give a power-gain of the order of 10 to 20. This gain may be very greatly increased, however, by the use of positive feed-back. Feed-back is applied by circulating the direct output current through an additional winding on the cores. If the magnetic effect of this feed-back winding is in such a direction as to reinforce that of the input current, there is partial self-excitation which increases the ratio of output current to input current. The effects of feed-back are closely analogous to those obtained with thermionic amplifiers, and excessive positive feed-back will give rise to instability. Positive feed-back is commonly utilized to obtain power gains per stage of the order of 2,000. Without feed-back a magnetic amplifier does not discriminate between positive and negative input signals; but with the application of feed-back, reversal of the polarizing flux changes the feed-back from positive to negative, and discrimination results. Magnetic amplifiers commonly operate with input powers of the order of a microwatt, and it is stated in one of the papers that 10^{-9} watt may be regarded as the lower usable limit of input power.

Perhaps the most significant difference between the behaviour of the magnetic amplifier and that of the thermionic amplifier lies in the time delay of the response of the magnetic amplifier to a sudden change of input. The build-up of the steady state following a sudden alteration of input is approximately exponential, and the response-time of magnetic amplifiers is usually expressed as the time-constant of an approximately equivalent exponential rise. This time delay, which is practically inversely proportional to the frequency of the A.C. supply and increases in proportion to the stage amplification, is one of the important limiting factors in the application of magnetic amplifiers. In order to obtain a high ratio of amplification to time-constant it is desirable to connect a number of stages in cascade, since the overall amplification is the product of the amplifications of the individual stages, whereas the total time-constant is, very roughly, the sum of the time-constants of the stages.

It is interesting to note that in the two papers the theoretical analysis proceeds along quite different lines, and different approximate-design techniques are developed. It is pointed out that a magnetic amplifier to control a given power output is ordinarily considerably larger than the corresponding power transformer, and supply frequencies in the range 400–1,600 c./s. are commonly employed in order to reduce the size of the equipment. The equivalent exponential delay of an amplifier is stated to correspond to a time-constant of the order of 2–100 cycles of the supply frequency.

JAMES GREIG

RECRUITMENT AND TRAINING FOR THE IRON AND STEEL INDUSTRY

IN order that the continuous and rapid technical developments in the iron and steel industry shall not outrun the capabilities of the men who will be required to operate the processes involved, the British Iron and Steel Federation has recently prepared recruitment and training schemes to benefit the industry as a whole. Based on the experience gained by various firms who have already developed training programmes of a far-reaching character, the Recruitment and Training Committee of the Federation has introduced a sample training scheme which has been circulated to all member firms. In order that the scheme should be fully discussed and improved, a Conference was held at Ashorne Hill, Leamington, on January 14–16, 1949, under the chairmanship of Mr. Gerald Steel, joint managing director of the United Steel Companies. The Conference was attended by representatives of member firms from all parts of Britain, and included production managers as well as personnel officers of various grades.

Pointing out that the number of youths in industry between the ages of 14–18 years had fallen from 3¼ millions in 1938 to 2½ millions in 1947, Mr. A. Goodram, of Samuel Fox and Co., Ltd., discussed the training of the junior operative both from the economic and social points of view. In his own Company the scheme began with a period of three weeks pre-entry training in which the change-over from school to work was cushioned and gave the boy and girl some idea of the shape and importance of the firm and of its general organisation. The boy's first job as a messenger lasted eight months, and during this time he obtained more information about individuals, departments and processes. The next phase of training was given in the workshops, when suitable boys were selected as craft apprentices. Junior operatives were then placed in production departments until they were called up for National Service; but during this time they would be given experience in at least three departments as well as opportunities for attending educational institutions on one day a week.

The director of training at Stewarts and Lloyds, Ltd., Mr. Graham Satow, then outlined a scheme for training craft apprentices and suggested re-introduction of the formal method of 'agreements'. Training should include both technical and general aspects, and should be the joint responsibility of the firm and the local education authority. For the more able apprentice, education up to the ordinary and higher national certificate standards should be provided, while for the craftsman who was good with his hands a less academic examination should be instituted. Practical training should be done by the firm, and should include experience in the use of hand and machine tools as well as the actual jobs associated with the boy's future work. Selected craft apprentices should be given both the opportunity of moving up to the technical apprentice-level and of sitting for State technological scholarships.

In opening a discussion on the training of technical apprentices, Mr. Cleghorn Thomson, chief education officer of Richard Thomas and Baldwins, Ltd., indicated that these would generally be recruited from grammar school boys of matriculation standard. His suggestions for training this type of apprentice presupposed that ultimately the heads and chief assistants in the chemical, metallurgical and fuel departments of the larger works would all be honours degree men, or associates of the appropriate professional bodies, that ordinary degree men would be in charge of the main sections under them, and that foremen testers and senior chemists and testers should have at least higher national and national certificates, respectively. Training of technical apprentices in the works should provide progressive movement linked up with their theoretical studies and success in examinations. The period of training would last about five years and would include time spent in other firms. During the ensuing discussion the doubt was expressed whether it would be practicable to insist on matriculation as the prerequisite for this type of entrant to industry, while the need for universities to provide more facilities for part-time studies was strongly advocated.

The training of clerical workers was introduced by Mr. D. R. O. Thomas, chief education officer to the United Steel Companies, who emphasized that this was an aspect of industrial training which had not been given the attention that its importance required and merited. The national certificate in commerce had not yet gained wide acceptance mainly because it had not been sponsored by any single authoritative body. This situation may be altered after the Carr-Saunders Committee, which is deliberating at present, has reported. The training should include preliminary instruction in the history and organisation of the firm, practical training in various departments and, concurrently with the practical training, theoretical training at a commercial college which should not be over-weighted on the vocational side. In summing up this particular session, the chairman insisted that the training provided "must wipe out that unfortunate figure, the routine clerk keeping up appearances on a miserable pittance".

Probably the most difficult subject at the Conference, training in the small firm, was tackled by Mr. A. Roebuck, technical director of Hadfield's, Ltd. Training in the small firm is as necessary as in the big firm, and Mr. Roebuck believed that this would be achieved if small firms would co-operate in groups on a trade or geographical basis. This is already happening in some parts of Great Britain, and in order to extend training facilities throughout the country it is proposed to set up local committees in various steel-making areas to help in the organisation of suitable training schemes. In this way large and small firms would be able to help each other, the small firm often making a contribution to training which was impossible in the bigger firm.

In surveying the work of the Conference, Mr. Geoffrey Summers, director of John Summers and Sons, Ltd., emphasized that all technical training needed to be reinforced with social and humanistic education in which young industrial workers should be taught how to make their leisure a period of profitable active enjoyment.

The Conference closed on an evangelical note with the following remarks by Mr. G. Steel. "We must proselytize. We must make everyone training-conscious. For the welfare of our own industry and the country as a whole, it is essential that we succeed. Only thus can we ensure that the best possible use is made of our strictly limited resources."

These words, and the calling of the Conference, indicate the way in which the iron and steel industry in Britain is adjusting itself to become more and more efficient in a world that daily grows more competitive.

T. H. HAWKINS

POTATO VIRUS X

THE drastic roguing which is performed on crops of potatoes for seed has resulted in a reduction of the amount of the more obvious viruses leaf-roll and rugose-mosaic. Potato virus *X*, however, causes a slight mottle of the foliage which is noticeable only under certain conditions of weather, and may often be missed by the roguers. F. C. Bawden, B. Kassanis and F. M. Roberts conclude, in a recent paper (*Ann. App. Biol.*, 25, No. 2, 250–265; June 1948), that the control of virus *X* must involve methods additional to those of field inspection. Presence of the virus in a stock of potatoes can be tested by inoculation to indicator plants and by serological methods. Spread of the virus is slow under natural conditions, and the authors conclude that the maintenance of stocks from which virus *X* has been eliminated by testing is feasible under commercial conditions. The virus reduces yield by 5–24 per cent; but it is refreshing to find the idea of clonal selection also considered along with questions of yield and loss due to virus.

Potato virus *X* is shown by F. M. Roberts (*Ann. App. Biol.*, 35, No. 2, 266–278; June 1948) to be transmitted by contact of leaves or roots. About ten per cent of healthy plants in contact with diseased.

ones become infected, and the more virulent strains of the virus spread more rapidly than the less virulent ones. The rate of spread is much greater in tomato than potato plants. *Datura stramonium* and tomato, indeed, become infected when grown in soil containing only sap or residues from virus-infected plants. The fungus *Rhizoctonia solani* cannot effect transfer of virus *X*.

Variations in the properties of virus *X* have been studied by F. C. Bawden and A. Kleczkowski (*J. Gen. Microbiol.*, 2, No. 2, 173; May 1948). Concentration of the virus extract by high-speed centrifugation or precipitation with acids and salts results in an insoluble form of the virus which is, nevertheless, infective and serologically active. Ribonuclease readily hydrolyses the nucleic acid derived from virus *X*, but has no action on the active virus.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, March 28—Wednesday, March 30

Chemical Society (joint meeting with the Chemistry Division of the Atomic Energy Research Establishment, at Rhodes House, South Parks Road, Oxford).—Symposium on "The Chemistry of the Heavy Elements".

Tuesday, March 29

Manchester Geographical Society (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. Wm. A. Singleton: "Impressions of Sweden".

Institution of the Rubber Industry, London and District Section (at Caxton Hall, Caxton Street, London, S.W.1), at 7 p.m.—Prof. H. W. Melville, F.R.S.: "Redox Polymerization". (Members of the Plastics Group of the Society of Chemical Industry are invited.)

Pharmaceutical Society, Manchester, Salford and District Branch (in the Council Chamber, Houldsworth Hall, Manchester), at 7.45 p.m.—Dr. C. Melville, Mr. H. Steinman, Mr. J. B. Lloyd and Mr. H. Burlinson: Papers on "Different Aspects of Pharmacy".

Wednesday, March 30

Physical Society, Colour Group (at the Royal Photographic Society, 16 Princes Gate, London, S.W.7), at 3 p.m.—Ninth Annual General Meeting; at 3.15 p.m.—Discussion on "Photoelectric Spectrophotometers and Tricolorimeters" (to be opened by Dr. T. Vickerstaff)

Manchester Literary and Philosophical Society, Chemical Section (at the Portico Library, Mosley Street, Manchester), at 5.30 p.m.—Dr. Hill: "Chemistry at the Shirley Institute".*

Royal Institute of Chemistry, London and S.E. Counties Section (joint meeting with the British Association of Chemists and the Association of Scientific Workers, at Gas Industries House, 1 Grosvenor Place, London, S.W.1), at 6.15 p.m.—Discussion on "Part-time Education in Chemistry".

Wednesday, March 30—Friday, April 1

*Institute of Metals (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1, on March 30 and 31, and at 4 Grosvenor Gardens, London, S.W.1, on April 1), at 10 a.m. each day—Annual General Meeting.

Thursday, March 31

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—108th Annual General Meeting; at 3.30 p.m.—Sir Ian Heilbron, F.R.S.: "Concerning Amino-acids, Peptides and Purines" (Presidential Address).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Mineralogical Society (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 7.15 p.m.—Mr. H. Marsden: "Nylon Yarn Processing in U.S.A.".

Thursday, March 31—Monday, April 4

British Psychological Society (at Bristol).—Annual General Meeting.

Friday, April 1

Chemical Society (joint meeting with the Chemistry Division of the Atomic Energy Research Establishment, at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 9.30 a.m.—Discussion on "The Use of Radioactive Tracers in Chemistry".

Society of Public Analysts and Other Analytical Chemists, Physical Methods Group (in the Chemistry Lecture Theatre, The University, Highfields, Nottingham), at 3.30 p.m.—Discussion on "Electrophoretic Analysis".

Institution of Mechanical Engineers, Applied Mechanics Group (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Dr. F. P. Bowden, F.R.S.: "Seizure of Rubbing Surfaces"; Dr. J. R. Bristow: "The Measurement of Kinetic Boundary Friction or the Experimental Investigation of 'Oiliness'".

Royal Statistical Society, London Group of the Industrial Applications Section (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, Strand, London, W.C.2), at 6 p.m.—Mr. C. Wainwright: "Statistical Principles in Quality Specifications for Plastics".

Society of Chemical Industry, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—Mr. H. V. Potter: "Synthetic Fibres" (Jubilee Memorial Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. S. Tolansky: "The Examination of Crystal and Metal Surfaces using Interferometry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physical Chemists (Scientific Officer grade) at a Ministry of Supply Research and Development Establishment near London, for duties in (*a*) high temperature refractories, (*b*) crystallography and practical microscopy, (*c*) spectrography, and (*d*) plant development—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1025/48A (April 2).

Senior Scientific Officers and Scientific Officers (with a good honours degree, or equivalent, in physics, and an interest in photography from high-speed aircraft and in air survey photography) at the Royal Aircraft Establishment, Farnborough, Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.43/49A (April 2).

Responsible Lecturer in Mechanical Engineering, and a Lecturer in Mathematics—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (April 2).

Physicists (Senior Scientific Officer and Scientific Officer grades) in Ministry of Supply Research and Development Establishments in South England and South Midlands—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.42/49A (April 2).

Senior Experimental Officer in Ministry of Supply Headquarters, London, for the co-ordination of thermionic valve requirements and supervision of an information service on valves for Government Departments and associated organisations—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting D.69/49A (April 2).

Lecturer (qualified to teach up to B.Sc. general degree standard in Mathematics) in the Physics and Mathematics Department—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (April 2).

Senior Assistant in Physics at the Bradford Technical College—The Director of Education, Town Hall, Bradford (April 2).

Ventilation Engineer in the Production Department at the Board's Headquarters in London—The National Coal Board, Establishments (General) Branch, Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/126 (April 4).

Lecturer (Grade IIb) in Industrial Metallurgy—The Secretary, The University, Birmingham 3 (April 9).

Engineers or Physicists in the Hydraulics Research Organization (Department of Scientific and Industrial Research) for work in connexion with the design and development of new instruments for hydraulics laboratory and oceanographic research—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.51/49A (April 9).

Principal Scientific Officer (Ref. F.134/49A) to be responsible, under the Superintendent, for research on chemical, physical and engineering problems of flax cultivation and processing, a Senior Scientific Officer or Scientific Officer (Ref. A.36/49A) for research in connexion with fibre grading and testing, etc., a Scientific Officer (Ref. F.135/49A) to undertake research into some aspects of chemical and biological retting, etc., a Senior Experimental Officer or Experimental Officer (Ref. F.136/49A) to take charge of the chemical testing and analytical section, and an Experimental Officer or Assistant Experimental Officer (Ref. A.37/49A) to take charge of the technical library and information section, at the Norfolk Flax Establishment, King's Lynn—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (April 9).

Director of the Marine Biological Station which is being established at Bangor to develop the facilities for the study of Marine Biology within the University of Wales—The Secretary and Registrar, University College of North Wales, Bangor (April 9).

Lecturer in Agricultural Zoology—The Secretary of University Court, The University, Glasgow, W.2 (April 12).

Senior Biochemist to direct the research activities of a cell metabolism unit at the Australian Institute of Anatomy, Canberra—The Chief Medical Officer, Australia House, Strand, London, W.C.2 (April 14).

Lecturer in Pharmacology—Prof. J. H. Gaddum, Pharmacology Department, The University, Edinburgh (April 15).

Assistant in the Department of Natural Philosophy, University College, Dundee—The Secretary, The University, St. Andrews (April 15).

Lecturer (Grade III) in Geography—The Registrar, Queen Mary College, Mile End Road, London, E.1 (April 22).

Chemist to assist in research with radioactive isotopes—The Secretary and House Governor, Royal Cancer Hospital, Fulham Road, London, S.W.3 (April 22).

Lecturer in Animal Husbandry and Management, and a Lecturer in Pathology and Bacteriology, in the Veterinary School, Gordon Memorial College, Khartoum—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (April 23).

Principal (woman)—The Secretary, Studley College, Warwickshire (April 29).

Post-Graduate Studentships (3) for research into stored products entomology in the Colonial Empire—The Under-Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1 (April 30).

I.C.I. Research Fellowships in bacteriology, biochemistry, chemical engineering, chemistry, chemistry of leather manufacture, chemotherapy, colloid science, colour chemistry and dyeing, engineering (civil, electrical or mechanical), fuel and refractories, metallurgy, pharmacology physics, textile industries (protein chemistry)—The Registrar, The University, Leeds 2 (April 30).

Lecturers in Chemistry (special qualifications in physical chemistry required for one post and in technical chemistry for the other)—The Secretary, The University, Edinburgh (April 30).

Lecturers and Senior Lecturers in Physics—The Secretary of University Court, The University, Glasgow, W.2 (May 31).

Nuffield Research Studentships and Fellowships for experimental and theoretical research in nuclear physics—The Professor of Natural Philosophy, The University, Glasgow, W.2 (May 31).

Research Fellowship in Metallurgy—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (June 1).

Science Graduate, for bureau literary work—The Director, Commonwealth Bureau of Animal Health, Veterinary Laboratory, New Haw, Weybridge, Surrey.

Senior Physicist to take charge of the researches on the physical aspects of rubber science and technology—The Secretary, Research Association of British Rubber Manufacturers, 105 Lansdowne Road, Croydon, Surrey.

Senior Technician (special knowledge of V.D. pathology essential)—The Pathologist, London Hospital Whitechapel Clinic, London, E.1.

Lecturer (up to B.Sc. standard) in Mathematics—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Physical Chemist or Physicist for research on the manufacture, properties and use of whiting, and an Information Officer to deal with library, abstracting and information services—The Director of Research, British Whiting Research Laboratories, 235 Ampthill Road, Bedford.

Lecturer in Botany—The Registrar, University College, Exeter.

Assistant Director of the Game and Tsetse Control Department, Government of Northern Rhodesia—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Chief or Senior Technician to take charge of the biochemical laboratory—The Chemical Pathologist, Hospital for Sick Children, Great Ormond Street, London, W.C.1.

Lecturer, and two Assistant Lecturers and Demonstrators (one part-time) in the Department of Physiology—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

University Graduate (with first- or second-class honours in botany) for bracken investigations—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen.

Laboratory Assistant in the Department of Biochemistry—The Secretary, University College, Gower Street, London, W.C.1, endorsed 'Biochemistry/2'.

THE BRITISH SCIENTIFIC INSTRUMENT INDUSTRY

ON two occasions during the latter half of the war period, attention was directed in these columns to the important contribution which the scientific instrument industry would be called upon to make towards the rehabilitation of every phase of life in Great Britain, and to the achievement of normal national prosperity. The experience of the post-war years has shown that the demands made upon the manufacturers of scientific instruments have not merely been heavy; but, in consequence of the necessity imposed by economic circumstances for an accelerated achievement of industrial production and efficiency greatly in excess of pre-war standards, even more arduous than had been anticipated. The manufacturers of scientific instruments were, in common with members of many other industries, completely immersed in the war effort, and had not the opportunity—nor were they permitted—to indulge in any post-war planning. It is appropriate, therefore, at this distance from the termination of the War, to review the position and condition of this vital industry and to assess its ability to meet the very heavy responsibilities which still rest, and will continue to rest, upon it.

It is well to remember that the functions of a scientific instrument industry are far more complicated and diverse than was the case a generation or so ago. At that time, the predominant activity of the manufacturer of scientific instruments was concerned with the provision of instruments for educational, laboratory and research purposes. The main commitment of the instrument maker was to meet the demands of pure science; and, as a consequence, not only was there intimate contact with the world of science, but also something of the laboratory atmosphere permeated the scientific instrument works. To-day, while the fulfilling of the requirements of pure science remains a vital function of the instrument industry, yet the greatest demands for instruments come from the world of applied science, and in particular of industrial science. It should also be borne in mind that the scientific instrument industry is not a single industry, but is, in fact, a collection of several individual industries. The techniques of manufacture of the microscope maker have little in common with those of the maker of electrical instruments. The problems of the manufacturer of instruments of metrology differ markedly from both. This lack of common ground in manufacturing technique between different classes of instruments connotes an equal diversity in the scope of development work required to be undertaken by the industry, and it is not always realized that the total development effort of the industry has to be divided into numerous classes of development projects which are as diverse in their nature as are instruments themselves. The magnitude of the development field which has to be covered by the manufacturers of scientific instruments cannot be over-stressed, for much of the impatience which is more than occasionally shown towards the scientific instrument industry arises from the complete preoccupation of a particular section of users with a particular class of instrument, and a consequent—and, let it be said, understandable—over-estimation of the proportion of the total development capacity of the industry for dealing with particular development projects. Nevertheless, the ability to produce new instruments and to modify existing types of instruments to meet new and urgent requirements does provide the 'acid test' of the efficacy of the instrument industry and the main symptom of the state of its health. It is, however, appropriate that a timely reminder should be given of the onerous nature of the instrument maker's commitments in the development field, and to remark that only a very flourishing scientific instrument industry can hope to meet those commitments with adequacy.

Opportunities have occurred in the displays of instruments at successive British Industries Fairs, in the annual exhibitions sponsored by the Physical Society such as that held in London during April 5–8 at the Imperial College of Science and Technology, and in the trade shows at Stockholm and Copenhagen, of judging the progress made by the scientific instrument industry of Britain, which, it can be said, without much exaggeration, had almost to make a fresh start at the conclusion of the War. At the Copenhagen exhibition, the comments on British instruments were most favourable, and some sense of astonishment was expressed by Scandinavian users, whose practice it had been to obtain all their instruments from the Continent, at the range of instruments shown and at the excellence of their design. There can be little doubt that there is no longer any substantial measure of validity in the criticism so often levelled at the scientific instrument industry of Britain in the past, that it exhibited weakness in its design and engineering activities. A comparison of post-war and pre-war British instruments cannot but reveal that remarkable progress has been made, and clearly indicates the very considerable effort which has been made by scientific instrument makers. These developments have occurred at a time when instrument manufacturers have been called upon to make the greatest possible effort to increase the export trade in instruments. At the moment, British scientific instruments to the value of £10,000,000 a year are being exported, as compared with some £2,000,000 before the War. This diversion of instruments abroad has necessarily had an unfavourable impact on the dates of delivery of instruments to the user in Great Britain.

The effort which the industry has already made to revive its production of civil instruments after its long pre-occupation with military requirements, and to assist the general economy of the country by making its contribution to the export drive, has undoubtedly and inevitably placed some limitation on the magnitude of its development effort. In consequence, it has not been found possible for the instrument maker to meet in every case the eager demand of instrument users for new and particular types of instruments; yet the addition which a considerable export trade has made to the resources of the industry ought to mean that all users' requirements should be met in an increasingly adequate degree. There is little need to stress the vital character of the part which, in this technological age, instrument production plays in the life of an industrial nation, and the increasing dependence of the work of the men of science on the provision of specialized instruments. The ability of the scientific instrument industry to play this part is, however, dependent upon its total volume of trade, and the recent expansion of its export trade was welcomed as offering potential resources which would enable the provision of scientific instruments in Great Britain to be achieved in a more worthy and complete manner than ever before. The revival of the German scientific instrument industry, in economic circumstances which are particularly favourable to that revival, does therefore create a problem, the solution of which demands serious attention. The official prognosis is that the trade in British instruments must inevitably shrink; this, in the long run, can only mean that the ability of the instrument manufacturer to meet, through his research and development activities, the continuous and varied requirements of instrument users in Great Britain, must correspondingly decrease. Such a situation cannot be faced with equanimity, since its repercussions are so vital and so widespread. The soundness of the reasons which have compelled the Allied control authorities in Germany actively to assist industrial revival is patent. The implications of that revival in respect of the ability of the British scientific instrument maker adequately and abundantly to produce scientific instruments, which provide the means of scientific research and the key tools of industrial efficiency—and ultimately profoundly affect the amenities and standard of life—should, however, not be forgotten. The problem is more complex than appears at first sight, and should be given very serious and practical thought.

CARBOHYDRATE CHEMISTRY

Chemistry of the Carbohydrates

By William Ward Pigman and Rudolph Maximilian Goepp, Jr. Pp. xvii+748. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1948.) 10.80 dollars.

The Chemistry of the Polysaccharides

By Dr. Robert J. McIlroy. Pp. vii+118. (London: Edward Arnold and Co., 1948.) 10*s*. 6*d*. net.

An Introduction to the Chemistry of Carbohydrates

By John Honeyman. Pp. vii+144. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 15*s*. net.

FEW fields of investigation in organic chemistry have shown more rapid or more spectacular advances than has been the case with the carbohydrate group. Once methods had been developed for precise structural determinations of the monosaccharides and disaccharides and their derivatives, a vast range of natural products became open for detailed study. The position then reached (1929) was depicted in Sir Norman Haworth's classical memoir "The Constitution of Sugars". Since that time the carbohydrate group has been the subject of continuous and intensive investigation by physical, chemical and biochemical methods, with the result that considerable further insight has now been gained into the molecular structure of the polysaccharides, including celluloses, starches, glycogens, pectic materials, plant gums and mucilages, and bacterial polysaccharides.

These developments in the chemistry of complex substances of high molecular weight are by no means the whole story. The simple sugars also have shown an amazing versatility of reaction and, selecting only one or two examples, we may recall the progress made in the study of the anhydro-sugars, the sugar alcohols, ascorbic acid and its analogues, and the amino-sugars. Much has been learned also of the behaviour of sugars towards enzymes, notably in regard to the mechanism of alcoholic fermentation and muscular contraction, and concerning the enzymic synthesis and break-down of amylose, amylopectin and glycogen. There is, therefore, an urgent need for new text-books which will incorporate these recent advances, and the books now under review may be taken as representative of three different approaches to the problem of recording knowledge in this field.

"Chemistry of the Carbohydrates", by W. W. Pigman and R. M. Goepp, is a large-scale monograph which provides a comprehensive survey of the broad field with full literature references up to 1946–47. It contains a wealth of information, including details of historical developments, and will be indispensable to all postgraduate students and research workers on the carbohydrate group. The material is clearly and accurately presented with adequate diagrams, and very little that is of importance in carbohydrate chemistry has escaped the authors' notice. The book, however, does not claim to be as comprehensive and detailed as the "Tollens–Elsner Handbuch" of 1935, and, from the point of view of the research worker, it is not so conveniently arranged. The difficulty seems to be that the authors have attempted to combine in one volume the features of a reference book with those of a large-scale text-book, with the result that, despite the careful and elaborate system of indexing, it is often difficult to track down a particular item of information. One could cite, for example, the way in which references to partially methylated sugars are scattered through the volume, while in the chapter which is designated "Ethers, Anhydrides and Unsaturated Derivatives" little collected information on the methyl ethers is provided. As a test case, let the reader attempt to ascertain from the book how to prepare 4-methyl glucose. The volume does, in fact, contain a literature reference pointing to this topic, but it appears unexpectedly in a section on optical rotatory power (p. 515) and does not appear in the index. The book is, however, the only one of its kind in the English language, and in view of its clarity and comprehensiveness (the index alone occupies 100 pages) it will be given an enthusiastic welcome by all who are seriously concerned with sugar chemistry.

R. J. McIlroy's "The Chemistry of the Polysaccharides", deals mainly with modern work on polysaccharides, a field in which new knowledge has been accumulating so rapidly that the author has been compelled to add an appendix giving advances which took place while the main body of the book was being printed. The accounts are clear and precise, with useful and adequate literature references. Their brevity is such, however, that they are likely to be of greater value to postgraduate students than to readers seeking some general knowledge of main achievements in polysaccharide chemistry. There is a most useful chapter on the methods of estimation of sugars, but it would have been more profitable to utilize the space devoted to "Derivatives of the Monosaccharides" for a more detailed description of the polysaccharides.

The third book on the list, J. Honeyman's "Chemistry of Carbohydrates", can be unreservedly recommended as an excellent introduction, on modern lines, to the structural chemistry of the sugars. It presents clearly the fundamental background of the subject, with the arguments set out in a way which renders the book specially valuable for undergraduate instruction and for readers who wish to obtain a general picture of this field. The scope is strictly confined to the structural chemistry of the sugars; but within this range the book contains a balanced account of the methods used in the investigation of both the simple and complex carbohydrates, with well-chosen examples to illustrate the results achieved.

E. L. HIRST

HINDU LIFE THROUGH THE AGES

Hindu Kinship

An Important Chapter in Hindu Social History. By Dr. K. M. Kapadia. Pp. xvi+320+xxxv. (Bombay: Popular Book Depot, 1947.) 15 rupees.

INDIAN sociology has for long been a subject of lively activity among anthropologists working in the field. Their activities have been devoted to the study of existing institutions, in all their variety, on the Indian sub-continent. Historical studies based on the study of literary documents, and so forth, have been pursued to a much less extent in this field. Yet it is important that such investigations should not be neglected, since these social organisms can only be fully understood in the light of their historical evolution and by the analysis of their diverse origin. Dr. K. M. Kapadia's book is therefore to be welcomed. It consists of a detailed and careful analysis of the data to be found in Sanskrit literature dealing with the family and its organisation. The author has decided to call his book "Hindu Kinship" rather than "Brahmin Kinship" because of the Brahmin habit of setting "the stamp of orthodoxy wholesale on many religious beliefs and social relationships that were alien to their own culture". Nevertheless, the subject-matter of the book corresponds more to a title "Brahmin Kinship". This is mainly what is dealt with in the law books and other literature which are analysed here. Practices outside the orthodox field are referred to casually, rather than systematically, and as exceptions to the norm rather than as constituents of different systems.

Beginning with the cult of the Manes, which is prominent from the earliest period, the author proceeds to the subjects of marriage, family organisation, adoption and affiliation, inheritance and succession, vicarious liabilities, and debts, and birth and death impurities. All these are subjects which are exhaustively treated in Sanskrit law books and allied tracts. Dr. Kapadia's book is in a way more philological than sociological, in the sense that its main pre-occupation is to find out what the texts really say. This is as it should be, since without a solid philological basis the material cannot be safely used for further work. It is also historical, so far as the chronology of the texts allows, and such changes as have occurred in the course of three thousand years are followed in detail. What is noteworthy is the small amount of change, at any rate in the orthodox interpretation, that has taken place in this period. The patriarchal pattern of family life which was introduced by the Aryan invaders remained in its essential principles unchanged throughout the history of Hinduism. The main course of development is an increasing strictness in the upholding of the various restrictions applied in this field, and to some extent an increase in their number.

Dr. Kapadia has provided for students of sociology a comprehensive and reliable account of this subject as it is found in the Hindu law books. Most of the essential material that is available is collected and presented here in a clear and systematic manner.

MATERIA COSMETICA

The Principles and Practice of Modern Cosmetics

By Ralph G. Harry. Vol. 2: Cosmetic Materials; their Origin, Characteristics, Uses and Dermatological Action. Pp. xi+479. (London: Leonard Hill, Ltd., 1948.) 35s.

MR. R. G. HARRY'S book passes under a sober English title, and perhaps the flamboyant Latinesque alternative could scarcely exist; yet it would have seemed almost permissible to invent it for a work as well-informed in scientific facts and as carefully responsible in its verdicts, as one could require in the treatment of the materia medica. The comparison is the more readily prompted by the pharmacopœial design of the book, in an alphabetical series of monographs, each subheaded with the synonyms, composition, provenance, properties, toilet uses and dermatological effects of its subject.

The author, indeed, refers specifically to the "diminishing gap between toilet manufacture and the preparation of remedial and healing skin creams", and deals judiciously with such medicinal constituents as penicillin, vitamins and hormones. A comprehensive and very readable monograph on "Herbals" reviews the claims of herbal ingredients, from early tradition down to recent findings on the bacteriostatic effects of chlorophyll and of plant juices from many different genera. Other topics in which the author carries the concept of 'cosmeticology' well beyond that of pure adornment are antiseptics, insecticides, insect repellents, sun-screening compounds and depilatories. Here, as elsewhere in the book, medical and dermatological findings are amply illustrated by references to original papers.

Space is also found for the treatment of such adjuncts to preparative manipulation as activated carbon for refinement of oils, fat-antioxidants and preservatives for finished products, and 'distilled water' prepared by adsorption. The greater part of the book, however, is naturally concerned with the basic materials of those creams and emulsions of which so many cosmetics largely or wholly consist. These include the following: most types of dispersing agents, for example, sulphated and sulphonated fatty bodies, quaternary ammonium salts, and soaps both organic and inorganic; dispersible fats and waxes such as those of the 'Lanette' type, wool-wax steroids and the 'mono-ester' class derived from fatty acids and polyhydric alcohols; the cellulose ethers and ether-esters, and alginates. It is hard to recall any previous treatment of the fatty group which supplies so much valuable matter in so concise a form. Thus, the thirteen pages devoted to fatty esters of polyhydric alcohols discuss in detail the manufacture and uses of the class, and give the usual 'fat constants' for twenty-seven American and twenty-eight British types—mono- and di-stearates (oleates, laurates, etc.) of glycerol, of ethylene and propylene glycols, and of mannitol and sorbitol.

It will be clear that the value of these sections is not only for the specialist in cosmetics. Most of the substances described have many other applications; one may cite the use of dispersible fats and emulsions in foodstuffs. The problem they present to the general analyst has so far been comparable to that which would be presented by the natural oils and fats if no accumulated data of iodine values and other 'fat constants' were available. That the two problems can be reduced to exactly the same footing is unlikely, if only because the caprices of manufacturers outnumber those of Nature herself; but Mr. Harry's contribution is a highly serviceable one, especially in that he has clearly enjoyed the confidence and co-operation of many leading manufacturers both in Great Britain and the United States.

One remains, indeed, a little uncertain as to how far the book has reference to British practice and how far to American. Pharmacopœial standards, which are given where relevant, refer to the "British Pharmacopœia". The standard specifications given for eleven generally used materials such as beeswax, borax and glycerin are those of the United States Toilet Goods Association. "British Industrial Methylated Spirit" is accorded a monograph, but except for a mention of denaturant use under "Diethyl Phthalate" there is no guidance on denaturing to British Excise requirements; yet sucrose octa-acetate has a monograph solely in virtue of its use as a denaturant, which is surely very infrequent in Great Britain. The use of the insect-repellent 'Indalone', which must be practically confined to the United States, is recorded, as is the similar application of dimethyl phthalate; but the discussion of diethyl phthalate omits its common British use in conjunction with the dimethyl compound; and dibutyl phthalate is not noticed. The colouring matters described are those 'certified' by the United States Food and Drugs Administration; this section has, however, a well-considered preface on the significance of the United States regulations and the desirability of similar British control.

This survey, though by no means fully exhibiting the scope of the book, will indicate the great variety of its matter and the amount of cross-reference involved in its most profitable use. For such use the simple alphabetical arrangement seems scarcely adequate, especially as there appears to be no consistent rule of titling the monographs either by commercial or by scientific names. Thus, 'Cellofas' (sodium carboxymethyl cellulose) figures under its trade name, while 'Collocel' (sodium cellulose glycollate) is under its chemical name. Other similar examples could be quoted. Though the book must already represent a most formidable labour of compilation, a detailed index would seem a merely just expenditure of tar for so gallant a ship.

E. G. KELLETT

The Theory of Solutions of High Polymers

By A. R. Miller. Pp. vii+118. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 12*s.* 6*d.* net.

THIS is a specialized monograph on a topic of great current interest. The thermodynamical behaviour of high-polymer solutions is of importance for many reasons. First, molecular size and shape can be determined if sufficient is known of the physical properties of the solution. Second, the intrinsic interest in the problem is a challenge to the theorist to get to grips with an exceptionally difficult problem. Even the proper understanding of the kinetic behaviour of high-polymer solutions is dependent on accurate knowledge of the system.

High-polymer solutions at all concentrations deviate so much from ideal behaviour that no slight extension of the theory of solutions is sufficient even to cover the case of very dilute solutions. Before the problem can be tackled statistically an acceptable model must be chosen. Dr. A. R. Miller therefore makes his choice and proceeds to develop the consequences, using all the laws of statistical thermodynamics. The first step is to calculate the free energy of mixing on the basis that the solution is athermal. Although there is not, unfortunately, a wealth of experimental data, the agreement between theory and experiment is surprisingly good, and demonstrates conclusively that the theoretical attack is along the right lines. When this simplification does not hold, matters are a good deal more complicated, and there are still discrepancies to be cleared up; but again the matter is put on a solid theoretical footing. More experimental work is needed to provide the basis for the construction of more accurate models suitable for statistical treatment.

H. W. MELVILLE

Flora of South Australia

(Handbook of the Flora and Fauna of South Australia, issued by the South Australian Branch of the British Science Guild, now incorporated with the British Association for the Advancement of Science.) Part 2: Casuarinaceæ–Euphorbiaceæ. By J. M. Black. Second edition. Pp. 253–521. (Adelaide: Government Printer, 1948.) 8*s.* 6*d.*

A SECOND edition of J. M. Black's well-known "Flora of South Australia" is in course of publication. The part recently received deals with the families of Dicotyledons from Casuarinaceæ to Euphorbiaceæ inclusive, essentially in the sequence of Engler and Gilg's "Syllabus der Pflanzenfamilien". Keys, descriptions and illustrations combine to make this a very practical flora. It is issued by the South Australian Branch of the British Science Guild (now incorporated with the British Association for the Advancement of Science.)

Families of particular interest include Casuarinaceæ, Proteaceæ, Chenopodiaceæ, Amarantaceæ, Aizoaceæ, Cruciferæ, Leguminosæ, Rutaceæ and Euphorbiaceæ. The species of Proteaceæ are less numerous than in some other States of the Commonwealth, and are represented by eight genera, of which *Hakea* with fifteen species and *Grevillea* with the same number are the largest genera. The Chenopodiaceæ, besides containing a considerable number of introduced weeds, are well represented in coastal and dry country habitats. *Bassia*, with 31 species, *Kochia* with 24, and *Atriplex* with 31 (of which three are introduced) are the largest genera. Many of the species of Cruciferæ are introductions, but there are a number of genera endemic to Australia, such as *Blennodia*, *Menkea* and *Phlegmatospermum*, while a few widely ranging genera, as *Lepidium*, have species limited to Australia. The largest family included in this part of the flora, the Leguminosæ, has many endemic genera and endemic species of more widely distributed genera. *Acacia*, with 89 species, is important taxonomically and ecologically in South Australia, and probably gave considerable trouble to key. *Pultenæa*, with 24 species, and *Swainsonia*, with 30, are other large genera. A large number of clovers and medicks have been introduced.

W. B. TURRILL

An Introduction to Organic Chemistry

By Prof. Ira D. Garard. Third edition. Pp. xi+396. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1948.) 21*s.* net.

THE author's aim is to give a concise rounded-off course of organic chemistry for students such as those of agriculture, home economics and medicine to whose main studies chemistry is ancillary. The contents comprise the simpler aliphatic and aromatic compounds usually described in an introductory course, together with a suitable scheme of practical work. Each chapter ends with a list of problems for study and a list of references.

By omitting matter requiring effort, such as the application of modern theories of valency to structure and reactions, and by stressing the economic uses of organic compounds, the author has made a most readable book. Thus we find him discoursing on proteins, rubber, nylon and dyes not only attractively but also in the light of modern knowledge. Prof. Garard handles his descriptive matter skilfully; his account of the paraffins includes the cyclic isomers, and his particularly well-written chapter on fats contains seven tables of information. His exposition of unusual terms such as 'azeotropy' and of new materials such as 'aerosols' is alike simple and adequate. For the above class of students this is a stimulating and interesting book.

G. F.

The Pharmaceutical Pocket-Book

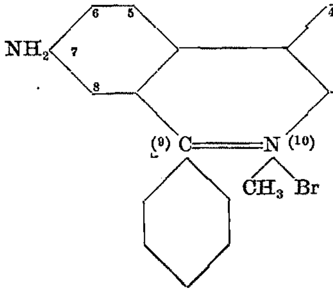
Fifteenth edition. Pp. x+430. (London: Pharmaceutical Press, 1948.) 12*s.* 6*d.*

"THE Pharmaceutical Pocket Book" has come to serve two purposes. It introduces students of pharmacy to the principles on which their profession is based, and it serves as a book of reference for the practising pharmacist. The new edition includes the many changes introduced by the new "British Pharmacopœia" which was published in 1948, and a summary of those provisions of the National Health Service Act which affect pharmacists. There are 20 pages devoted to biochemical analysis and 10 pages of notes on bacteriology. There is a dictionary of synonyms and trade names which occupies 77 pages. This is a formidable, but in some ways a disappointing, list. It is devoted mostly to archaic and picturesque synonyms which cannot be much used nowadays. It contains devil's dung, dragon's blood, doom bark, essence of smoke, hippo wine, little liver pills, madweed, mandrake and nihil album, but not benadryl or neoantergan, 'DOCA', 'BAL', mapharside, 'DFP', dolantin, demerol, priscol, paludrine or promin. The list would be more valuable if it was brought up to date. There should surely be, either here or somewhere else in the book, a guide to modern synthetic drugs. However, the book contains much information and will, no doubt, serve a useful purpose.

CHEMOTHERAPY OF *T. CONGOLENSE* INFECTIONS WITH PHENANTHRIDINE COMPOUNDS: BIOLOGICAL ASPECTS

By PROF. C. H. BROWNING, F.R.S.
Department of Bacteriology, University of Glasgow

IN the editorial article, "Sleeping Sickness and Nagana" (*Nature*, January 15), mention is made of phenanthridine compounds in the treatment of cattle infected with *T. congolense*. The following details are likely to be of interest for their theoretical bearing and also because more than two million doses of one of these drugs, 2 : 7-diamino-9-phenyl-10-methylphenanthridinium bromide (No. 1553 or 'dimidium bromide', see formula), have been administered to cattle in Africa, and very considerable outbreaks of trypanosomiasis have been controlled by its use (*The Times*, February 9).



Formula of No. 1553

Phenanthridine compounds synthesized by the late Sir Gilbert Morgan and Dr. L. P. Walls at the Chemical Research Laboratory of the Department of Scientific and Industrial Research, Teddington, were examined by us for anti-infective properties (antiseptic[1], etc.), the work being supported by the Medical Research Council. *Inter alia*, it was found that 7-amino-9-*p*-aminophenyl-10-methylphenanthridinium chloride (No. 897) had definite chemotherapeutic action on experimental infection in mice both with *T. brucei* and *T. congolense*, although the effective dose approached the toxic limit[2].

In view of the refractoriness of *T. congolense* to most chemotherapeutic agents which act powerfully on *T. brucei*, and the serious economic effects of African cattle disease caused by the former, the work was continued. We then observed that a much smaller dose of compound No. 897 than originally stated was capable of sterilizing *T. congolense* infection[3]. On exploring this discrepancy, the knowledge gained enabled therapeutic experiments to be conducted under fairly uniform conditions. Also, for the first time apparently, a drug with powerful curative action on *T. congolense* was available. Accordingly, a study has been made of the responses of this parasite to chemotherapeutic agents, several strains being used[4,5].

It was discovered that *T. congolense* undergoes biological changes according to the duration of the infection, which markedly affect its therapeutic sensitiveness. In order to obtain consistent results, it is essential always to transfer the trypanosomes to a fresh mouse as soon as they become abundant in the blood, that is, at 'acme'. A strain so maintained is termed an 'acme strain'. After acme the parasites either may persist in the blood in large numbers for several days to many weeks, until the animal finally succumbs to the infection, or a relapsing course may be established, the number of trypanosomes in the blood fluctuating greatly from time to time and death occurring during an access. In general respects, the condition in mice resembles passably the natural disease in cattle. An occasional striking feature in heavy protracted infections in mice is stasis in the tail and ears, which become dark purple-red and undergo necrosis unless treatment is given.

When the infection becomes chronic (that is, when the animal lives for more than several days after acme), a larger dose of the drug is required for sterilization than suffices at acme. Further, this diminished therapeutic response is shown also in fresh animals inoculated with such a 'chronic variant' strain. It is noteworthy with the acme strain that when treatment is administered at an early stage of infection, before parasites have become abundant in the blood, a larger dose of the drug is required to effect cure than at acme. This contrasts with *T. brucei* infections in mice and suggests that the immunity reaction following destruction *in vivo* of *T. congolense* plays a very significant part in bringing about sterilization—at least through the agency of phenanthridine drugs. The trypanosomes derived from a chronic infection have also the characters of a 'relapse strain', that is to say, an animal sterilized of an infection with the acme strain, while immune to re-inoculation with the same strain, becomes infected on re-inoculation from a chronically infected mouse. This relapse character may persist for a considerable time when such a chronic variant strain is subjected to a series of passages. Eventually, however, the original acme character seems to become re-established. (Our various acme strains were obtained by prolonged acme-passage through mice until the infection became accommodated.) The relapse strains of *T. congolense* showed a remarkable difference from those of *T. brucei* originally described by Ehrlich. A mouse cured of infection with a relapse strain of the latter is susceptible to the original strain; but this is not the case with *T. congolense*. However, later work has shown that this feature is not exhibited by all acme strains of the parasite; for example, animals cured of infection with a chronic variant of the 'Busimbi' strain are not immune to re-inoculation with the corresponding acme strain[6].

Of the series of phenanthridine compounds prepared by Dr. Walls[7] the most effective against *T. congolense* is No. 1553 (*vide supra*)[5,8]—with mice the ratio of the maximum tolerated dose to the minimum curative dose (more than 50 per cent cured), injected subcutaneously at acme, being 400 : 1 to 40 : 1 according to the strain. With No. 897 the ratio is 100 : 1 to 10 : 1; the less favourable results of Fulton and Yorke[9] may be explained by the early stage at which treatment was carried out[8]. We have not yet compared 'Antrycide' under similar conditions; but no other substance so far known approaches No. 1553 in efficacy (see also Wien[10]). In infected cattle the superiority of No. 1553 over No. 897 was also manifest. Of course, in cattle the 'therapeutic index' is much lower[8]; but a single dose of No. 1553 at the rate of 1·5–2·0 mgm. per kilo of body-weight injected into the tissues or intravenously is usually well borne and appears to be the standard curative dose (Carmichael and Bell[11]). Neither No. 897 nor No. 1553 protects normal mice for longer than a few days (less than four or five) when a large dose is injected subcutaneously and the animals are afterwards inoculated. Prophylactic action in cattle for two to four weeks has been reported, however (Crawshaw[12], Stewart[13]).

The occasional occurrence in cattle, some weeks after treatment, of toxic symptoms resembling photosensitization (Bell[14]) has been an undesirable complication of therapy with phenanthridine No. 1553. The precise conditions determining the development of those effects have not been defined. Similar phenomena have been recorded apart from treatment, and nothing comparable has been produced in small rodents (Brownlee *et al.*[15]). Where cure fails to occur in cattle, the relapses seem generally to be less amenable to further dosage with phenanthridine drugs. This soon emerged with No. 897, and has been attributed to the rapid acquisition of drug-resistance by the trypanosomes. But our persistent attempts to produce drug-fast strains in mice by the various known methods have failed; for example, where repeated relapses were on each occasion treated with a single injection of a dose curative for less than 40 per cent of original infections at acme, sterilization was effected ultimately in the same proportion, cure resulting even after the twentieth relapse[4,5]. The diminished therapeutic response in relapsed cattle seems similar to our observations with chronic strains in mice. By analogy, it is possible that drug-fastness of the trypanosomes may develop more readily in one species of host than in another. But the problem as regards cattle requires more extensive investigation than it seems to have received so far.

On comparing acme strains derived originally from different natural sources, marked differences were found in virulence, susceptibility to the chemotherapeutic drug and 'solidity' of immunity to re-inoculation with the homologous strain following cure[4,5,8]. As regards immunity, with one strain animals were refractory to a single massive re-inoculation more than a year after cure, or to repeated re-inoculations over this period. This suggests a method of protecting herds by artificial inoculation followed by treatment. On the other hand, with another strain only 50 per cent of animals resisted re-inoculation even after recent cure; and of these again, 50 per cent became infected after a second re-inoculation and so on. Little or no cross-immunity exists between different acme strains. Those differences have persisted without noteworthy change during many years of 'syringe-passage'. It remains to be determined whether in their natural habitat strains from cattle in one locality show considerable uniformity, or whether a variety of strains with distinct characters exist side by side in the same place.

T. vivax infection (in cattle) also responds to the phenanthridine compounds which are effective against *T. congolense*; but no member of the series is very potent toward *T. brucei*. *T. cruzi* infection in mice (one strain tested) is influenced by certain members[16], especially 3-carbethoxyamino-9-*p*-carbethoxyaminophenyl-10-methylphenanthridinium chloride (or methanesulphonate) and also 2 : 7-dicarbethoxyamino-9 : 10-dimethylphenanthridinium methosulphate, neither of which acts on *T. congolense* or *T. brucei* except in maximal doses.

METEOROLOGY IN AGRICULTURE

THE ordinary meeting of the Royal Meteorological Society on March 16 took the form of a discussion of weather problems in farming, three speakers presenting prepared papers. As these papers could not be circulated in advance, they had to be read in full, so that general discussion was restricted in time, and would have been even more so if one of the three had not been self-sacrificing by confining himself to a few comments.

Opening the meeting, Dr. H. L. Penman directed attention to three kinds of problem: statistical, biological and physical. Statistical problems include, among others, the forecasting of both weather and crop yields. Of the former, he said that when they could be obtained, long-range forecasts would be of immense value; but even the scope of present-day forecasting technique could be made more useful to farmers, and this point was emphasized in the later discussion by Dr. J. Meiklejohn, who urged the establishment of a regional forecast service designed in language and scope for the particular needs of farmers and not exclusively for the benefit of agricultural scientists. Dr. Penman stated that attempts to forecast crop yields from weather data had a long history of failure, a failure due to neglect of the biological side of the problem; but in spite of his plea that future activity of this kind should start with biological measurements, Prof. Dudley Stamp asked that more meteorological measurements should be taken to help land utilization experts and town planners to do their job less harmfully to farming interests. Another contributor to the discussion, Mr. A. W. Ireland, from the Sudan, pointed out that yields of irrigated cotton can be predicted with considerable certainty merely from a knowledge of rainfall before sowing.

Biological problems, Dr. Penman continued, involve quantitative study of the growth, spread and decay of biological activity and their dependence on weather, and present a wide field for research in general and local meteorology and in micro-meteorology, in which the objective must be to answer some particular biological question. Some of these problems present a challenge to meteorological physicists on their own ground, for turbulent transport of spores and pollen involves the same ideas as turbulent transport of heat and water vapour, but are at least one degree more difficult because the suspended material has a terminal velocity of settling too big to be neglected in the analysis. Physical problems of importance in farming include not only the analysis of this turbulent diffusion, but also study of the heat balance of the earth—always of importance, but particularly so in investigating early summer radiation frosts—and of the water balance, since water is indispensable in any system of farming.

As an illustration of the application of fundamental physical research to practical farming, Dr. Penman then outlined work recently done at Rothamsted on the relation between weather and water consumption by crops. Because of the large latent heat of vaporization of water, much of the incoming energy from the sun is used up in evaporating water—if the water is there to be evaporated—and by measuring or estimating other components of lesser importance it is possible to draw up an energy balance-sheet in which the only unknown is evaporation. This theoretical work can be employed in practice to estimate the transpiration-rate from a fresh green crop with an adequate water supply, given measurements of wind speed, air temperature, dew-point temperature and duration of bright sunshine. The condition of 'adequate water supply' being the condition aimed at in any good irrigation system, the treatment is directly applicable to irrigation control. To demonstrate this, he described an experiment on irrigation of sugar beet on a Surrey market garden during 1948 in which one of the irrigation treatments was controlled on the basis of data returned weekly from a small weather station set up on the experimental field. In the course of the summer, irrigation was called for three times (total applied, 2·6 in.), but in all cases subsequent rainy periods rendered these irrigations superfluous, or almost so. In addition to unirrigated control plots, a third set was irrigated at the farmer's discretion (five times; total applied 4·7 in.), but because natural rainfall was estimated to have been entirely adequate, no major differences in yield were expected. Nor were they obtained, though there was a slight, non-significant bias in favour of the plots that had restricted irrigation. Soil samplings before and during the cropping confirmed the weather-based estimates of the amount of moisture removed by the crop.

Dr. L. Broadbent then gave a survey of the weather problems encountered by biologists, with particular reference to the potato. His main concern was the intervention of weather in attempts to produce full yields of healthy potatoes; but he commented also on problems of storage in clamps and the degree of thermal and physical insulation that must be provided to prevent too rapid heat loss in cold, moderately calm weather and to prevent penetration of cold air in windy weather. Logically, it can be interpolated here that Mr. R. W. Gloyne also made a brief reference to deterioration of 'seed' potatoes during transit from Scotland to southern England, and the problem of determining night radiation losses of heat from the railway trucks in which the potatoes are carried.

The need for this annual transfer of seed took up the greater part of the remainder of Dr. Broadbent's paper. Because of the weather conditions in the seed-raising areas and the general absence of winter host plants for the insect vector, the seed from Scotland arrives almost, if not completely, free from virus disease. Odd tubers, however, might have such a disease, and potatoes left in the ground from an earlier crop might have it, so that invariably all English potato crops carry a few nuclei of infection. The infection is spread by the aphid, *Myzus persicæ*, and Dr. Broadbent gave an interesting account of his experiments to determine those micro-meteorological conditions within the potato crop that would lead to insect movement from plant to plant, or inhibit it; since the insect carries the disease with it, the study of spread of the disease is, in fact, largely the study of the movement of the insect. He first showed the inadequacy of Stevenson screen temperatures as guides to what is happening inside the crop, and although in the later discussion there were some good-natured sallies against such screen readings, the chairman, Mr. E. Gold, clearly expressed the feeling of the meeting in stating that while for general synoptic surveys the standard screen is adequate, for particular problems data would have to be collected in other ways. To this Mr. W. H. Hogg added the comment that night minima in the screen seem to be reasonably representative of those measured in Dutch lights at ground-level.

Dr. Broadbent also gave an account of work, largely exploratory and still in the pioneering stage, aimed at measuring temperature and humidity gradients, and the degree of air movement, inside potato crops of different spacings and vigour. The aphid will not fly if the air-speed around it is more than 3–4 m.p.h.; but even the early results show conclusively that flying conditions may often be suitable inside the crop when they are unsuitable outside, so that a chance eddy, or an imprudent excursion, may take the insect out into the faster-moving air to be swept uncontrollably along to another part of the same field, to another field, or even to another county—carrying infection with it if it was previously feeding on an infected plant.

It was unfortunate that Mr. R. W. Gloyne, of the newly formed Agricultural Branch of the Meteorological Office, had to compress his remarks, but even so he gave a fascinating glimpse of his activities as meteorological attaché to the south-west province of the National Agricultural Advisory Service in Britain. He, too, was concerned with potatoes, not only with the transit of seed and storage of tubers but also with the possibility of issuing special weather forecasts of the imminence of the hot humid conditions that lead to rapid multiplication of the spores of potato blight, one of the few diseases that has a clearly marked and fairly well-known association with a particular type of weather. Of special forecasts in general, he, like a later contributor to the discussion, pointed out that farming has to go on whatever the forecast, and that we must be careful not to over-estimate the value of farmers' weather forecasts, particularly for men working on a small scale. For large units, however, such forecasts might realize their expected value.

The scale of farming activity and its dependence on weather appeared also in another of his topics, which he referred to as "farming climatology". Many harvesting operations, of which haymaking is an outstanding example, can only be successfully carried out if there is a certain weather sequence, usually of days without rain, at the time of the operation; the amount of crop that can be successfully harvested is limited by the length of this suitable period, by the labour and equipment available for the job, and by the technique used for the operation. For a given size of farm with normal staff and equipment, the optimum area of crop will be limited by the probability of getting the necessary weather sequence and by the harvesting technique. For hay, eastern England can count on a long sequence of good haymaking days, so the technique used there may not be equally successful in the south-west with its higher and more frequent rainfall; the most effective technique for the south-west would be one making some allowance for the climate of the region.

A further general topic led Mr. Gloyne to a point of particular interest. As is well known, dusting and spraying techniques against insect attack and plant pathogens are, like the spreading of some fertilizers, at the mercy of the wind. The wind-speed above which control becomes very difficult varies with particle-size and spreading technique; but it is usually a long way below gale force, and for finer materials may be only a few miles an hour. When the material is suspended or dissolved in water, high-pressure spraying is usually successful; but there are areas so short of water that it must be applied as a dust, and the problem arises of finding some means of making the dust stick to the plants. A heavy dew deposit will serve, and Mr. Gloyne had been asked if it would be possible to get forecasts of occasions on which early mornings of heavy dew would be followed by conditions calm enough for dusting operations to be carried out without undue loss by blowing away.

Mr. Gloyne's final remarks would be broadly accepted by most present: meteorology should be more concerned with growing food and less with getting an aeroplane from place *A* to place *B*; and an early resumption of the discussion was highly desirable.

H. L. P.

NUTRITION AND FERTILITY

THE War accentuated the difficulties of food production and the maintenance of an adequate diet for human use. Actual destruction and the diversion of human activity to destructive aims, mass movements of the population to avoid or assist military operations, and the natural increase of the population, which in spite of these disturbances continued with very little check, have brought peace-time problems of great urgency: how to maintain or raise the standard of nutrition, and at the same time make provision for the increasing population or alternatively how to control the rate of increase. Nutrition and fertility are therefore socially and economically related as well as causally connected. The emphasis of the Conference held by the Nutrition Society on March 5 was on the causal connexions, but many experiences were drawn from the social and economic spheres. Thus, Dr. G. I. M. Swyer directed attention to the apparent paradox that in the East (China, India, etc.) a high birth-rate and expanding population is associated with poverty and under-nourishment, whereas in the West adequate nourishment is associated with a stationary or declining population. Prof. A. St. G. Huggett, on the other hand, instanced the effects of starvation or near starvation on the depression of the conceptual-rate, birth-rate and birth-weight, and increase in abortion-rate and prematurity-rate, in the populations of Stalingrad and Holland during the worst periods of the War. Dr. J. Edwards showed that data collected from animal artificial insemination centres primarily concerned with increasing the milk production could be analysed to give valuable information on the effect of seasonal nutrition on bovine fertility. Dr. J. Hammond and Dr. S. J. Folley both drew inferences on the effects of nutrition on fertility from agricultural practice, and Prof. Huggett and Dr. Swyer from clinical medicine.

This approach to the subject from a wide field of generalizations necessarily brought to light the existing lack of exact knowledge on many subjects, which was particularly evident in the case of nutritional therapy. The Conference succeeded, however, not only in directing attention to gaps in our knowledge but also summarized much original and recent research.

Dr. J. Hammond, in his paper on "The Physiology of Reproduction in Relation to Nutrition", gave a very broad review. The onset of puberty is determined by factors outside the gonads; immature ovaries implanted into adult animals function immediately; mature ovaries implanted into immature animals do not function until puberty is reached. The activity of the gonad and body-growth are determined by the hormones of the anterior pituitary, and normally the onset of puberty occurs as the adult growth-rate diminishes, so that the onset of puberty must depend upon a balance of output between the growth hormone and the gonadotrophic hormones. A very high plane of nutrition may reduce the time of onset of puberty, but the weight of the animal at puberty is increased. In the mammal this may be a disadvantage by causing a diversion of nutrients from the embryo and mammary gland to the body tissues. Conversely, poor nutrition leads to delay in the age of puberty, but puberty occurs at a lower body-weight than normal. In this case pregnancy and lactation place a considerable burden on the undergrown mother. Good nutrition increases the number of ova shed. The number of ova fertilized may depend upon the viability of the spermatozoa, and there is some evidence that this is affected by the nutritional condition of the male. Development of the sheep embryo during gestation is affected by the plane of nutrition. The birth-weight and viability of lambs born to ewes underfed during the later stages of pregnancy may be seriously affected and subsequent growth retarded by deficient lactation.

Dr. A. Walton, speaking on "Spermatogenesis and Nutrition", gave an estimate of seminal output in the male and showed how this is related to the total metabolic activity of the testes. The total weekly output of semen even during great sexual activity is extremely small and cannot be regarded as a serious drain on the nutritional requirements. The spermatozoon is a highly differentiated cell in some respects, but genetic argument leads to the conclusion that the nucleus contains half the genes which are common to the somatic cells. The locomotory apparatus and metabolism are similar in most respects to muscle.

Dr. J. Edwards, on "Variations in Fertility Levels in Bovines", analysed data from insemination centres to show that although cows are fed very differently during winter and summer, the conception-rate is not significantly affected. Contrary to common expectation, the lowest rate is found to be in the quarter of the year from April to June. Bulls show no striking effects of nutrition on semen output. Dr.

S. J. Folley, on "Nutrition and Female Fertility", dealt more specifically with the causal mechanisms of nutrition. Since reproductive activity is largely controlled through endocrine mechanisms, it is to be expected that nutritional effects will act through the endocrine glands. Evidence that anterior pituitary activity is affected by nutritional factors is available. For example, rats on a restrictive diet show no œstrous cycles, but respond to injections of gonadotrophic hormones. Atrophied accessory sex organs of rats on a diet deficient in B vitamins may be restored by injection of gonadotrophic hormones. Lowered pituitary function due to inadequate nutrition may be the cause of anœstrus during winter in heifers. A direct effect of nutrition on the ovary is not established, but since the œstrogen-level in the body is due to the balance between production by the ovary and excretion, deficiencies in the excretory mechanism may lead to syndromes similar to those set up by excess œstrogen activity in the ovary. B-deficiency (thiamin and riboflavin) and diets low in lipotrophic factors may affect the efficiency of the liver to inactivate œstrogens and lead to syndromes relating to sterility, such as pathological uterine bleeding. Evidence that nutritional factors may affect the responsiveness of the tract to œstrogens is provided by Herz, who found that the oviduct of chicks fed on diets deficient in folic acid did not respond to œstrogens; 20 μgm. of folic acid daily restored normal responsiveness. Some analogous results have been found in mammals.

Prof. A. St. G. Huggett, on "Nutrition and Viable Young", dealt in detail with a more limited aspect of nutritional deficiency, namely, the placental life of the embryo. Vitamin A deficiency results in a generalized metaplasia of epithelial surfaces. In the rat there is continuous keratinization of the vagina. Usually the fœtus goes to term but dies because the birth mechanism is upset. In severe cases, however, placental death and fœtal absorption may occur. Vitamin E deficiency has no action on rats before the eighth day from copulation, that is, three days after implantation. There are parallels between the action of E deficiency and experimental embryonic trauma. In both cases changes in the placenta result from destruction of the mesoderm tissues and allantoic blood flow. The fœtus is resorbed, but the trophoblastic placenta stays in position and is delivered at term. Apparently vitamin A deficiency kills the fœtus as a secondary effect of placental death, whereas vitamin E deficiency acts mainly on fœtal hæmatopoietic organs and leaves the decidua and trophoblast intact. Riboflavin deficiency in rats may result in many congenital deformities, but this effect only occurs during the early stages of pregnancy when apparently riboflavin is essential to early ossification. An interesting parallel occurs with rubella infection, which may result in congenital cataract or heart lesions if the mother is infected in the second month of pregnancy.

Dr. G. I. M. Swyer, who discussed "Nutrition and Human Fertility", was concerned mainly with clinical diagnosis and therapy. Gross under-nourishment results in amenorrhœa and menstrual disorders and a fall in conception-rate. Over-nourishment and obesity are commonly associated with infertility in women. Recent observations by Barton and Wiesner on refractory cervical block, which is common in sterile obese women, show that the condition responds with marked success to a dietary free from sugar. The precise way in which dietary sugar brings about the syndrome of obesity, genital infection and refractoriness to œstrogens is still obscure. Successful treatment of infertility with vitamin E has been much advertised. For the male the evidence is mostly negative or statistically inconclusive. For women there is evidence that habitual abortion may be successfully treated with vitamin E.

ARTHUR WALTON

OBITUARIES

Dr. A. Cunningham

By the death of Dr. Andrew Cunningham in Edinburgh on March 4, agricultural bacteriology has lost an outstanding figure. The son of a farmer, Cunningham was born near Glenfarg on August 26, 1890. From school at Perth Academy he proceeded in 1908 to the University of Edinburgh, and after graduating in agriculture in 1911 he worked for a year in the chemistry department of the Edinburgh College of Agriculture. Deciding to study bacteriology, he spent the following winter at the Lister Institute and King's College in London, and then proceeded to Leipzig, where he worked for a year under Felix Löhnis. There, his first investigation concerned plate counts of bacteria in soil and milk, and he showed the importance of long incubation at a low temperature if maximum counts are to be obtained. In Leipzig, also, he did some of the pioneer work on the Protozoa of soil and their influence on the soil microflora. Cunningham's future career seems to have been greatly influenced by Löhnis, and it may be more than coincidence that the two men bore a remarkably strong resemblance in temperament and scientific outlook.

After working for short periods at Berne, Shinfield and Rothamsted, Cunningham joined the army in 1915 and saw active service in France. On demobilization in 1919 he was appointed lecturer in bacteriology at the Edinburgh College of Agriculture. With characteristic energy he overcame the many difficulties of building up from virtually nothing an efficient teaching department. Six years later he exchanged the lectureship for the post of adviser in bacteriology, and he at once entered with enthusiasm into the work that continued until his death. In addition to his advisory duties, Cunningham was able for several years to devote much of his time to purely scientific work on the anaerobes of soil and manures. He found that some of the butyric acid bacilli displayed a life-cycle similar to that described in *Azotobacter* by Löhnis and Smith. This work, although its findings are still controversial, ranks as the most important in his career, and it provided material for the thesis accepted by the University of Edinburgh for the degree of D.Sc. in 1931.

Cunningham's published work covers a considerable range of agricultural subjects, including the bacteriology of silage and manures, methods of examining milk, taints in milk, and the inoculation of lucerne. In recent years he had been occupied principally in an investigation of bovine mastitis, where one may easily detect his carefully devised plans, which were carried out with determination and meticulous care. His "Practical Bacteriology for Students of Agriculture", which is now in its third edition, is widely recognized as one of the best books of its kind. Abstract journals appreciated his services as a writer of concise but informative and critical abstracts.

Cunningham will be remembered as a man with a forceful personality who frequently gave expression to his strongly held opinions and acute judgments. These qualities were combined with an exceptionally wide knowledge of bacteriology. He was invariably interesting and helpful as a contributor to scientific discussions, and he was a most useful member of committees. His health had been progressively deteriorating for some time before his death. He is survived by his wife, whom he married in 1921.

T. GIBSON

WE regret to announce the following deaths:

Dr. Sydney H. Ball, mining consultant to the U.S. War Production Board, known for his work on the geology of the United States and of the Belgian Congo, on April 10, aged seventy-one.

Prof. Jules Drach, member of the Section of Mechanics of the Paris Academy of Sciences, professor of analytical mechanics at the Sorbonne, on March 7, aged seventy-seven.

Dr. A. D. Imms, F.R.S., lately reader in entomology in the University of Cambridge, on April 3, aged sixty-eight.

NEWS and VIEWS

National Chemical Laboratory of India:
Prof. J. W. McBain, F.R.S.

IT is announced that Prof. J. W. McBain, who has recently retired from the chair of physical chemistry at Leland Stanford University, California, has been appointed the first director of the National Chemical Laboratory of India. It is difficult to think of a better choice. While his many English friends have not seen so much of him since he left the University of Bristol, yet they have been able to follow his steady development of the concept of the micellar structure of colloidal electrolytes, a chapter in physical chemistry which is particularly his own. The number of papers which have emerged from Bristol and Stanford is indeed prodigious, and the world is richer for the numerous students whom he has trained. Not only are we indebted to McBain for a great extension of our knowledge of the colligative properties of these solutions, as well as conductivity and surface action, but also the behaviour of such colloidal solutions in respect to the interesting properties of emulsions and emulsion polymerization, solubilization and the like, have been fully explored by him. While his main interest has lain in this field, we must recollect that we are also indebted to him for coining the word 'sorption', thus directing attention to the complexity of the interactions between a gas and a solid, and that his treatment of the subject of adhesion in the British Association Reports still remains a classic. His many friends and colleagues will wish him well in this new and important venture.

Royal Geographical Society: Awards for 1949

HIS MAJESTY THE KING has approved the award of the Royal Medals of the Royal Geographical Society as follows: *Founder's Medal*: Prof. L. Dudley Stamp, professor of geography, London School of Economics, for his work in organising and directing the Land Utilization Survey of Great Britain and his application of geography to national planning; *Patron's Medal*: Prof. Hans Pettersson, professor of oceanography at Göteborg Hogskola, Sweden, for his leadership of the recent oceanographical cruise in the *Albatross*, in the course of which much new evidence has been obtained as to the geology of the ocean floor. The Council of the Society has made the following awards: *Murchison Grant*: Lieut.-Colonel E. H. Thompson, for original researches in the techniques of air survey, and for the development of stereoplotting machines; *Back Grant*: Dr. Brian Roberts, research fellow of the Scott Polar Research Institute, for his contributions to polar history and to the technique of polar travel; *Cuthbert Peek Grant*: Mr. A. B. Crawford, for surveys and meteorological work carried out by him at Tristan da Cunha and Marion Island; *Gill Memorial*: Dr. O. H. K. Spate, reader in geography at the London School of Economics, for his work on the geography of India and Burma.

Scientific Liaison Officer in France:
Mr. A. H. Waterfield

IN agreement with the Foreign Office, the Department of Scientific and Industrial Research has appointed Mr. A. H. Waterfield, a principal scientific officer, formerly of the Ministry of Supply, for scientific liaison duties in France, with the rank of attaché at the British Embassy in Paris. Mr. Waterfield, who is a metallurgist with special experience in the light-alloy field, was formerly on the headquarters staff of the Ministry of Aircraft Production, later the Ministry of Supply, and during the past year has been secretary of the Inter-Service Metallurgical Research Council. During 1946–47 he was attached to the United Kingdom Scientific Mission in Washington for metallurgical liaison duties.

Royal Observatory, Greenwich: Transfer to Hurstmonceux

IN the House of Commons on March 25, Mr. Hollis raised certain important points about the conditions prevailing at Hurstmonceux and also regarding the delay in assembling the instruments and in providing adequate accommodation for the staff. Mr. Hollis dealt with a number of matters that have already been emphasized by the Astronomer Royal in the Report for 1948 to the Board of Visitors and repeated by the Chief Assistant elsewhere. Mr. Hollis urged that the work at Hurstmonceux should be given an extremely high priority and pushed forward with all dispatch. The cost of the building necessary to put the new Observatory into full commission amounts to about half a million pounds, and, while admitting that such an amount cannot be treated lightly, it was pointed out that the prestige of Great Britain has been highly valued on account of the position of the meridian of Greenwich, and that there are "few matters on which such a sum could be better spent". In addition to scientific issues, Mr. Hollis raised another point—the artistic problem of Hurstmonceux. The south side of the castle presents an unsightly spectacle with a number of temporary huts of brick and wood, and although they were not placed there by the Admiralty, it was suggested that the Admiralty should remove them. Further, when permanent buildings take their place, these should be screened from the castle. He asked for a guarantee from the Civil Lord of the Admiralty that the Royal Fine Art Commission should be consulted in the matter, and made some suggestions regarding the site of these new buildings.

Mr. Hollis was strongly supported by Major Tufton Beamish, who asked for full assurances that the local authorities should be consulted in the scheme, in which they are deeply interested. The Admiralty would receive the full co-operation and all possible help from the local bodies concerned in the transfer of the Royal Observatory to Hurstmonceux. Mr. Walter Edwards, Civil Lord to the Admiralty, gave certain assurances, and stated that the Admiralty would take the Royal Fine Art Commission fully into its confidence before the second or third stage is undertaken, and also that he was prepared to consider the question of taking the local authorities completely into consultation. He thought that the Observatory would be in a proper state, counting the war period, in a little less than fifteen years, which, presumably, implies about five years from the present time. It is the fervent hope of all who are interested in scientific progress in Great Britain that this expectation will be fulfilled.

Oscar Hertwig (1849–1922)

One of the founders of the science of heredity and one of Germany's most brilliant embryologists and comparative anatomists, Wilhelm August Oscar Hertwig was born a century ago, on April 21, 1849, in Friedberg, Hessen. A pupil of Schultze, Haeckel and Gegenbaur, he graduated at Bonn in 1872, and in 1881 became professor of anatomy in Jena. Seven years later he was appointed to the chair of general anatomy and embryology at Berlin and to the directorship of the newly created Anatomical-Biological Institute. He served as rector of the University during 1904–5. Retiring in 1921, he died on October 25 of the following year, aged seventy-four. A voluminous and authoritative writer, his works (some in collaboration with his brother Richard) went through many editions and were translated into several languages, for example, his "Lehrbuch der Entwicklungsgeschichte des Menschen und der Wirbelthiere". "Die Zelle und die Gewebe" (1893) in the second edition (1906) changed its title to "Allgemeine Biologie", for the author believed that the problems of the living body could be reduced to problems of the single cell. Hertwig was one of the first to teach that the physical basis of heredity must be sought in the chromosomes. His "Cölomtheorie" (1881) helped to complete Balfour's theory of the germinal layers. Perhaps his most important achievements were his discovery in 1875 of the process of fertilization in the sea-urchin, and his observation in 1890 of the first case of parthenogenesis in the animal kingdom—in a star-fish. For a number of years he edited the *Archiv für Mikroskopische Anatomie*. It is a curious fact that the disciple of Haeckel and Gegenbaur in the end apostatized from Darwinism.

Industrial Gas Turbine Development Committee

The Minister of Supply, anxious that all possible steps are taken to ensure that Great Britain exploits to the full the industrial applications of the gas turbine, has set up a Committee to keep this matter under continuous review and to make recommendations to him as to any further research or development work which the Committee thinks should be put in hand. Sir William Stanier is chairman of the Committee, which will also include, in addition to experts from interested Government departments, a number of independent members well known in combustion engineering circles. The composition of the Committee is as follows: Sir William Stanier (chief mechanical engineer, London Midland Region, British Railways); Sir Frank Whittle (adviser on operation and development of gas turbine aircraft to B.O.A.C.); Prof. O. A. Saunders (professor of mechanical engineering, Imperial College of Science and Technology); Sir Henry L. Guy (secretary, Institution of Mechanical Engineers); Rear-Admiral (*E*) D. J. Hoare (director of research, British Internal Combustion Engine Research Association); Dr. T. W. F. Brown (director of research, Parsons and Marine Engineering Turbine Research and Development Association); F. Shakeshaft (British Electricity Authority); Dr. D. T. A. Townend (National Coal Board); A. A. M. Durrant (British Transport Commission); Dr. F. M. Birks (British Gas Council); Sir Archibald J. Gill (General Post Office); Dr. H. Roxbee Cox (Ministry of Fuel and Power); Dr. G. A. Hankins (Department of Scientific and Industrial Research); Dr. A. Parker (Department of Scientific and Industrial Research); A. E. N. Taylor (Ministry of Transport); Sir Denys C. Ford and Dr. J. A. Carroll (Admiralty); J. Anderson and A. E. MacColl (Scottish Home Department); Capt. (*E*) M. Luby, H. Constant, Lieut.-Colonel P. E. Holmes and A. P. Wickens (Ministry of Supply).

Skipton Earthquake of 1944

Dr. H. C. Versey has collected macroseismic data concerning the Skipton earthquake of December 30, 1944 (*Trans. Leeds Geol. Assoc.*, 6, No. 2; 1948), which shows that the earthquake had an intensity 7 on the Davison scale at the centre of greatest disturbance near the Gargrave Fault. In the central area subsurface drains were broken, and damage was caused to a bridge. York was just within isoseismal 5, and Lincoln, Manchester and Carlisle were within isoseismal 4. Dr. Versey relates the centre of disturbance to the Craven Faults near the margin of the rigid block of north-west Yorkshire with its early Palæozoic and possibly pre-Cambrian basement rocks. Previous shocks at Kendal (March 17, 1871), Wetherby and York may also have been connected with the faulted boundaries of this rigid block. Sound phenomena associated with the Skipton earthquake were heard by various observers, particularly those situated inside isoseismal 6, who compared the sounds with the rumbling of vehicles or the rushing of a strong wind.

University of Edinburgh

The trustees of the Godfrey Thomson Research Fund have given £5,000 to the University of Edinburgh, and promised an annual payment of £1,000 (in the first instance up to 1952) to permit the establishment of a readership in educational research, the holder of which will be largely concerned with research into problems of testing and selection. The Godfrey Thomson Research Fund draws its income from royalties on the Moray House Tests, of which the fiftieth was recently completed, and on fees from county and city education authorities for the use of tests and for statistical advice. The five trustees of the Fund, which is devoted to educational research of all kinds, but especially the improvement of intelligence and aptitude tests, are appointed by the University of Edinburgh.

University of London

The title of reader in the University of London has been conferred on the following in respect of the posts mentioned: Dr. Moses Blackman (theoretical physics, Imperial College of Science and Technology); Dr. J. McG. Bruckshaw (geophysics, Imperial College of Science and Technology); Dr. S. H. Harper (organic chemistry, King's College).

Mr. Eugene Grebenik has been appointed to the University readership in demography tenable at the London School of Economics and Political Science as from October 1, 1949.

The degree of D.Sc. has been conferred on Mr. Allan Walkley (Rothamsted Experimental Station) and Mr. F. R. Selbie (reader in bacteriology, Middlesex Hospital Medical School).

University of Glasgow

The following appointments have been made: Dr. A. M. MacDonald (from Edinburgh) to be Gardiner lecturer in pathology of diseases of infancy and childhood; Drs. R. A. Raphael (Imperial College, I.C.I. Fellow), D. S. Payne (Imperial College) and Mr. G. L. Buchanan (University of Aberdeen) to be lecturers in chemistry; R. C. Curran (Stobhill Hospital) to be lecturer in pathology at the Royal Infirmary; C. A. Hopkins (Trinity College, Dublin) to be lecturer in zoology for veterinary students; Miss A. E. Nicolson, J. S. MacPherson and R. B. Walker to be assistants in mathematics; and Dr. C. M. McLean to be an assistant in ophthalmology. Dr. G. M. Badger is resigning his I.C.I. Fellowship to become senior lecturer in organic chemistry in the University of Adelaide.

Fourth International Gas Conference

The fourth International Gas Conference of the International Gas Union will be held, under the presidency of Colonel C. M. Croft, at the Institution of Civil Engineers, Great George Street, London, S.W.1, during June 15–17. During the mornings, papers will be read, followed by discussion, dealing with many aspects of the gas industry in Great Britain, the Continent of Europe and the United States. The afternoons will be devoted to excursions to gas works and associated industries and also to places of cultural interest. Full particulars may be obtained from the Secretary of the Institution of Gas Engineers, 1 Grosvenor Place, London, S.W.1. The annual general meeting of the Institution of Gas Engineers will precede the Conference, taking place during June 13–14.

Royal Photographic Society: Officers for 1949

At the annual general meeting of the Royal Photographic Society held on March 22 the following officers were elected: *President*, Percy W. Harris; *Vice-presidents*, L. V. Chilton and I. D. Wratten; *Treasurer*, H. Abbott; *Ordinary Members of Council*, Gilbert Adams, S. W. Bowler, G. Scott Bushe, J. Allan Cash, K. H. Gaseltine, P. Hansell, Miss M. Harker, R. G. Hopkinson, T. Midgley Illingworth, J. Dudley Johnston, H. S. Newcombe, Anthony Peacock, B. Sinkinson, A. L. McR. Sowerby and H. White.

"Production of Mesons by Electrons"

Dr. I. N. Sneddon and B. F. Touschek write, with reference to their communication under this title published in *Nature* of April 2, p. 524: "The second row of the table of numerical values gives $10^4 I(E)$ and not $10 I(E)$ as stated there. The second sentence of section (3) should be amended to read: 'By analogy with *Bremsstrahlung* we might expect the cross-section for an atom with charge Z to be larger by a factor Z^2. It turns out that this factor is incorrect, since for any nucleus a competing intermediate state occurs: . . .' Further, the factors occurring in the second last paragraph should read: 'Z for positive mesons, and $A-Z$ for negative mesons'. This changes the final cross-section to 10^{-31} cm.^{2}. It has been pointed out to us by Prof. J. C. Gunn, that the 'mixed term' in the Hamiltonian of the interaction between a meson and the electromagnetic field may give rise to an appreciable correction to the values of $I(E)$. This suggestion is now being considered and will be discussed in a future publication."

Announcements

A course on the application of air photography to planning will be held at University College, London, during July 18–29 under the direction of the professor of surveying and photogrammetry (Prof. C. A. Hart). The fee for the course will be ten guineas, and full details may be obtained from the Secretary, University College, Gower Street, London, W.C.1.

The second full-day conference on combined heat and power supplies, organised by the Institute of Fuel, will be held at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1, on April 27. This conference will deal with the interlinking of the heat and power systems of adjoining industrial plants, and also with the co-ordination of heat and power supplies and demands throughout a district. The conference will be open to the public, and full particulars may be obtained from the Secretary, Institute of Fuel, 18 Devonshire Street, Portland Place, London, W.1. For further consideration of general and regional aspects of the problem, the North-Western Section of the Institute is holding a conference on the same subject at the Engineers' Club, Albert Square, Manchester, on May 11.

The Department of Scientific and Industrial Research will consider applications for maintenance allowances from graduates (or equivalent) in science who wish to be trained in applied science, industrial research or technology. Such allowances may only be held in a university, institution or approved research association. Applications for the academic year 1949–50 must be made on Form 1*S* and must be completed before May 1. Full details may be obtained from the Department of Scientific and Industrial Research, Dorland House, 14–16 Regent Street, London, S.W.1.

Referring to the article entitled "Fracture of Solids" published in *Nature* of March 5, p. 376, Mr. M. W. Thring writes: "The report of Dr. Haward's observations is not quite correct in that the $\log T$, $1/S$ relation is ascribed wholly to Dr. F. W. Preston. This relation is based on Preston's work, but was published by Haward (*J. Soc. Glass Tech.*, 28, 427; 1944) prior to its independent publication by Preston (*Nature*, 156, 55; 1945)".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Inorganic Paper Chromatography

PROF. R. P. LINSTEAD kindly sent me a manuscript copy of the communication by Burstall, Davies, Linstead and Wells[1], and I should like to comment on this work in relation to my own.

Prof. Linstead and his colleagues mention that more precise separations were achieved by them by downward development; this technique was tried by me[3], but more constant R_f values are obtained by Williams and Kirby's method[4].

It is mentioned[1] that separations of gold, platinum, palladium, iridium and rhodium have been carried out by the authors. I have since devoted some more time to the platinum metals, including ruthenium and osmium, and intend to publish my results in the near future.

My results on the separation of the copper and tin groups were accepted by *Analytica Chimica Acta* on September 24, 1948, in advance of Arden, Burstall, Davies, Lewis and Linstead's first publication[2], and is at present in the press.

More recent work of mine includes the following. Silver chloride, mercurous chloride and lead chloride can be separated on a disk of filter paper by placing approximately 0·1 mgm. in the centre and adding two drops of water followed by two drops of $5N$ ammonium hydroxide as developing solvent. After exposure to hydrogen sulphide, this produces a centre patch of black mercury and mercury sulphide surrounded by a ring of silver sulphide, again surrounded by a ring of lead sulphide.

Divalent copper and cadmium can be separated by the technique described in ref. 3 by the use of 25 per cent ethyl alcohol as developer.

Divalent lead can be separated from divalent copper, cadmium and mercury, and trivalent bismuth by development with $1N$ aqueous hydrochloric acid; but the lead does not travel with the liquid front.

Using butanol saturated with $1N$ hydrochloric acid, the following R_f values were obtained:

Ion	R_f value	Ion	R_f value
Ag^{+}	0·0	Hg^{++}	1·02–1·10
Cu^{++}	0·08–0·13	Pt^{+++}	0·72–0·8
Cd^{++}	0·56–0·65	Rh^{+++}	0·07
Bi^{+++}	0·61–0·68	$RuO_4^{=}$	0·1
Pb^{++}	0·0	Ir^{++++}	0·72–0·8*
As^{+++}	0·67–0·73	Au^{+++}	1·05–1·13
Sb^{+++}	approx. 0·8*	Fe^{+++}	0·12
Sn^{++}	0·95–0·99	Co^{++}	0·07
$MoO_4^{=}$	0·5–0·53	Ni^{++}	0·07
UO_2^{++}	0·2	Mn^{++}	0·09
U^{++++}	0·0	Sr^{++}	0·0
Pd^{++}	0·6	Ba^{++}	0·0

* Further details are necessary.

Investigations with other solvents were also carried out; for example, hydrobromic, hydriodic, acetic, nitric and phosphoric acids, in butanol, etc.

On January 25, 1949, I submitted a paper to *Science* giving the details of the separation of chloride, bromide, iodide and thiocyanate ions, which is achieved by using butanol saturated with $2N$; the following R_f values were obtained:

Anion	R_f value
Cl^{-}	0·10–0·11
Br^{-}	0·15–0·18
I^{-}	0·29–0·32
CNS^{-}	0·42–0·48

For separation of smaller quantities a new technique, which I call micro-chromatography, was developed and announced to some of my colleagues in this field on December 31, 1948, in a private communication. Further details will appear in due course.

The above deals only with inorganic work. In addition, I have dealt with a number of theoretical points, including: a thermodynamical treatment of temperature variations; new aspects of 'comet' formation; generalizations concerning the effect of different anions on the R_f values of cations.

THE spread of interest in inorganic adsorption analysis using organic solvents, indicated in Mr. Lederer's communication above and in the recent letter from Pollard, McOmie and Elbeih[1], is welcome, as it does seem that the method will have wide applications. We have tried to make its possibilities generally known both in our preliminary communications[2], by demonstrations[3], and by privately advising a number of research laboratories on applications to their individual problems.

The further development of this method may proceed along many different lines. One possibility is to compare the behaviour of a large number of different metals with standard solvents or solvent mixtures. This could conceivably lead to the separation of complex mixtures of metals in two-dimensional chromatograms, rather as has been done with amino-acids. It is interesting that both Mr. Lederer and the Bristol workers are collecting comparative data suitable for this purpose. It is, of course, necessary to bear in mind that the rate of movement of a particular metal (as represented, for example, by its R_f value) may be affected by other ions present. Another line of attack is to devise special methods for particular and more limited mixtures. Thus a group of metals can be precipitated in some standard way, and paper chromatography used as a supplementary weapon for analysis or purification. This is a line of development which we think very attractive, and one topic which we are now studying particularly is the possibility of eluting one metal after another from a paper strip or column by successive changes of the extracting medium. Separations involving some forty-five metals and anions have so far been achieved in this Laboratory. Details will appear elsewhere.

In view of the increasing interest in this subject it may be well at this stage to make a few historical matters clear. The separation of organic substances from aqueous solutions by capillary analysis was first due to Goppelsroeder[4], while it appears that H. Trey[5] achieved the first clear inorganic separations by this technique. The fractionation of inorganic compounds in aqueous solutions by means of adsorption columns was first effected by Schwab and his co-workers[6]. The great advance of the separation of *organic* compounds on paper using organic solvents was due to Martin, Gordon, Synge and their collaborators[7]. We appear to have been the first to have described the use of *organic* solvents for separating *inorganic* materials on cellulose, although it now appears that work on these lines has proceeded independently in other laboratories. Our experiments in this field began in 1946 and were described in the Annual Report of this Laboratory for 1947 [8] and in subsequent communications[2].

We did not overlook Mr. Lederer's 1948 paper[9]; but it was not referred to individually in our previous letters as it dealt with aqueous solutions. For the same reason we did not detail all the earlier work with aqueous solutions, but confined ourselves to the remarkable improvements which are possible when organic solvents are used under the best conditions.

Mechanism of Nitration of the Aromatic Nucleus

IN order to check the constitution of preparations of the three different tritium toluenes carrying radiochemical amounts of tritium in the aromatic nucleus, samples were transformed into 2,4-dinitrotoluene with an excess of a mixture of 1 part (by volume) of concentrated nitric acid and 2 parts of concentrated sulphuric acid. An experiment in which inactive toluene was nitrated with a rather strongly active mixture of acids showed that no hydrogen exchange takes place under the conditions of the reaction. No activity could be detected in the dinitrotoluene, though it had been possible to record an acquired tritium : protium ratio as small as 1 per cent of that of the surrounding mixture of acids and water, even if only one of the organic hydrogen atoms had taken part in the exchange.

It was to be supposed that on dinitration toluene-4-t would lose all, and toluene-3-t none, of its activity. Toluene-2-t, finally, would lose an amount corresponding to the relative velocities of nitration in the two ortho positions, carrying tritium and protium, respectively.

The different organic molecules were burnt and the specific activities of the water samples determined[1]. In the calculation of the percentage of tritium remaining in the molecule after nitration, the different hydrogen contents of toluene and its dinitro derivative were taken into account. The accompanying table gives the results.

In the case of toluene-4-t some other isomer seems to have been present in the sample.

In the case of toluene-2-t, both experimental figures equal 50 per cent just within the experimental error, which implies that the nitration proceeds with very nearly the same velocity irrespective of whether tritium or protium originally occupies the position. In view of the great difference in mass (and therefore in the zero point energy of the original bond, the difference in which, however, may be more or less counterbalanced by a similar difference of the same magnitude in the 'activated complex' of the reaction, particularly if a base enters the complex[2]), it seems natural to suppose that the velocities should be different if the splitting off of the hydrogen takes part in the rate-determining step of the attack on the nucleus (which is not necessarily that of the reaction as a whole). Since there is no exchange of hydrogen with the acids and the water, the reason cannot be the existence of a dissociation equilibrium. The simplest way of accounting for the present observation seems to be the assumption of an addition of the nitrating agent (NO_2^+) [3,4] as the rate-determining step, followed by a rapid splitting-off of the hydrogen. The intermediate ion might have a quinonoid character.

Substance nitrated	Percentage of original tritium still present in the 2,4-dinitrotoluene	
	Theoretical	Observed
Toluene-4-t	0 per cent	2·2 per cent
Toluene-3-t	100	99·0
Toluene-2-t	(50)[*]	51·9; 49·7 (two exp.)

Kinetics and Mechanism of Aromatic Nitration

IN an earlier note[1] it was shown how the study of the kinetics of nitration, particularly the study of reaction order, established (*a*) the formation of the nitronium ion, and (*b*) its effectiveness as the entity which attacks the aromatic molecule. Further kinetic investigation, particularly of salt and solvent effects, has given information on two other general features of the reaction. They relate to (*c*) the reaction stages by which the nitronium ion is formed, and (*d*) those by which it becomes a nitro-group in the aromatic compound.

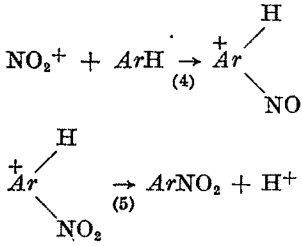
(*c*) The stages by which the nitronium ion is formed may be discovered by reference mainly to conditions in which the rate of nitration is equal to the rate of formation of the nitronium ion. For the formation of nitronium ion from nitric acid, the stages are as follows:

$$2HNO_3 \underset{(2)}{\overset{(1)}{\rightleftharpoons}} H_2NO_3^+ + NO_3^- \qquad \text{(1 and 2 fast)}$$

$$O_2N\cdot\overset{+}{O}H_2 \underset{(3)}{\rightarrow} O_2N^+ + OH_2 \qquad \text{(3 slow)}$$

The proof of this rests on a hyperbolic repression by nitrate ions of the rate of nitration ($v \propto c^{-1}$), without disturbance to the reaction order, even when it is of zero order. Other sufficiently strong acids, such as sulphuric acid, may replace one molecule of nitric acid in providing the proton required for the formation of the nitric acidium ion, as illustrated in (1).

(*d*) The stages by which the nitronium ion enters the aromatic ring are elucidated by reference mainly to conditions of nitration in which the nitronium ion is rapidly formed. The transformation of the nitronium ion into an aromatic nitro-group is a two-stage bimolecular process, the proton-loss having no kinetic significance:



$$NO_2^+ + ArH \xrightarrow{(4)} \overset{+}{Ar}(H)(NO_2) \qquad (4\ slow)$$

$$\overset{+}{Ar}(H)(NO_2) \xrightarrow{(5)} ArNO_2 + H^+ \qquad (5\ fast)$$

This follows because the solvent effect, under the conditions indicated, is small enough to show that ionic charges are neither formed nor destroyed in the rate-determining stage of the entry of the nitronium ion as a nitroxyl group into the aromatic molecule. The alternative possibility, that the reaction is a one-stage termolecular process, in which the proton-loss is kinetically important, requires the reaction to be base-accelerated, and therefore, since the strongest available bases are nearly always anions, requires ionic charges to be destroyed; for example:

$$NO_2^+ + ArH + SO_4H^- \xrightarrow{(6)} ArNO_2 + H_2SO_4.$$

Reaction (6) should be comparable to (2), or in an inverse sense to (1), in solvent sensitivity, and this the reaction between nitronium ions and aromatic molecules certainly is not. Reaction (4) should show a small solvent effect due to the spreading of the charge in the transition state; and the actual reaction does, indeed, exhibit such an effect.

We were commencing an investigation, in which we expected to confirm the kinetic insignificance of the proton-loss by showing that aromatic protium and deuterium are replaced by nitroxyl at the same rate, when Dr. Melander very kindly sent us word that he had just completed such a demonstration, but using tritium rather than deuterium. His work is conclusive (see preceding communication).

The effect of small amounts of water in accelerating nitration in sulphuric acid has been interpreted[2] as a mass-law effect on the basis of (6). We think that the phenomenon which in the simplest circumstances comes under observation here is the small solvent effect on (4). From the dielectric properties of sulphuric acid, and its behaviour in solvating cations, it seems certain that the first effect of added water must be to reduce solvating power, and thus to create a kinetic effect in the observed direction[3]. Actually a complication enters in nearly all real cases, as has already been pointed out[4]. It is that most substances of which the nitration-rates in sulphuric acid have been studied combine with the acid to form unreactive salt-like complexes, which added water will partly break up, thereby facilitating nitration. But when this effect is negligible or absent, the solvent influence on (4) remains as a factor which will cause a small initial acceleration by added water.

Monolayers of Collagen

PAST work on monolayers of gelatin on water has generally led to the conclusion that it is not suitable for such studies because of its high solubility[1]. This difficulty has been overcome with other proteins by spreading on strong solutions of ammonium sulphate[2], and we have found that stable monolayers of collagen can be formed on 30 per cent ammonium sulphate solution (*p*H 4) by spreading from formic acid solution. The surface pressure (π) and surface potential (ΔV) have been studied over a pressure-range of 0·01–30 dynes/cm. When the area (A) is greater than about 5 m.^{2}/mgm. the film is heterogeneous, large fluctuations of ΔV being observed as the ionizing air-electrode is moved over the surface, although no constant surface vapour pressure was found. As the film is compressed to areas smaller than about 5 m.^{2}/mgm. it becomes homogeneous and $\Delta V.A$ is constant. On further compression, two critical areas are recognized: (1) A_1 (1·8 m.^{2}/mgm.), below which values of $\Delta V.A$ fall, indicating a change in orientation, accompanied by a decrease in compressibility; (2) A_2 (1·3 m.^{2}/mgm.), which is derived by extrapolating the linear portion of the π—A curve (between 1·0 and 0·2 m.^{2}/mgm.) to zero pressure.

We suggest that these two areas correspond to close-packing of the polypeptides with their side-chains orientated (*a*) parallel to, and (*b*) perpendicular to the water surface. From existing data on the amino-acid composition of collagen[3], these areas are found to correspond to about 27·5 and 20 A.^{2} per mean residue, respectively. Calculations based on the mean side-chain length and Astbury's mean repeat distance of 2·85 A. for collagen give a value for A_1 of 28·2 A.^{2} per mean residue, assuming that ends of the 'mean' side-chains approach to within the H—H covalent bond distance. The determined value for A_2, of 20 A.^{2}/mean residue, is very near that for close-packed fatty acids, amides, etc., with the side-chains practically vertical. This area has been observed with several other proteins (for example, Philippi[4]). Compression to areas smaller than A_2 must result in the displacement or solubilization of parts of the film.

When collagen was spread on solutions of hydrochloric acid and sodium chloride, stable and reproducible films were formed when the film was initially spread at areas larger than A_1. Poor reproducibility resulted when the initial area was less than A_2. By studying the π—A curves over a range of *p*H values and salt contents, the following two distinct phenomena are apparent:

(1) At areas larger than A_1, the π—*p*H curves at constant area show a maximum at *p*H 2·2, sodium chloride causing the maximum to be depressed and, when present in sufficient amount, to disappear (see Fig. 1).

(2) At areas smaller than A_2, the π—*p*H curves show no maxima whether or not salt is present, π increasing as the ionic strength of the solution increases, that is, as the *p*H decreases (see Fig. 2). None of the π—A curves gives a linear portion which can be extrapolated to zero pressure.

At areas greater than A_1, where the molecules are probably orientated with the side-chains parallel to the surface, the dependence of the two-dimensional osmotic pressure (π) on *p*H and salt is similar to that predicted by the three-dimensional Donnan theory, or by consideration of the electrical properties of the film

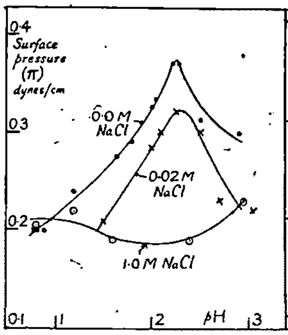

Fig. 1. Area = 2·5 m.²/mgm.

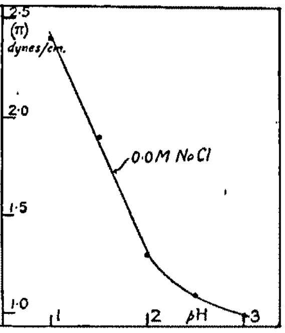

Fig. 2. Area = 0·5 m.²/mgm.

as deduced by Philippi[4] from the Gouy–Chapman treatment of the ionic distribution in the electrical double layer. At areas smaller than A_2, where it is impossible for all the film to remain in the surface, the action of both acid and salt appears to be that of 'salting-out' agents, the increasing ionic strength necessitating more work to cause displacement.

Measurement of the Elasto-Plastic Properties of Gels

Cheftel and Mocquard[1] used the deflexion of a vane embedded in a gel to record the relation between the deformation of the gel and the applied force.

Goldsmith and Iball[2] showed that, if the vane is attached to a torsion wire and deflected by an angle δ with the torsion head turned through an angle α, the blade deflexion at time t is given by

$$\ln \{\alpha/(\alpha - \delta)\} = Ct^k/\Psi, \qquad (1)$$

where C is a constant of the instrument, Ψ a constant of the gel denoting its firmness and k the dissipation coefficient. Equation (1), which thus permits calculation of the 'firmness intensity factor' Ψ, was found to be applicable to a number of different milk curds for which the index β of the applied stress was unity and where the elastic limit was exceeded at a negligibly small applied stress.

Further experiments have shown that the torsion method can also be used to find the rheological properties of gels which possess considerable elasticity. In this case, the apparent 'firmness intensity factor' is composed of an elastic and plastic component, the former being independent of time and thus determined by the shear strain at $t \simeq 0$, whereas the latter is dependent on the relation between shear strain and time at $t > 0$. A modification of equation (1) is thus necessary to account for the elasticity of the gel, the modified equation taking the form:

$$\ln \{\alpha/(\alpha - \delta)\} = C(1/E + t^k/\Psi), \qquad (2)$$

where E is the modulus of elasticity.

The following figures were obtained by means of equation (2) for the gels formed by 1 per cent solutions of commercial soaps at 25° C. ($\beta = 1$).

Sample	E (dynes/cm.²)	ψ (C.G.S. units)	k
I	7·0	261	0·590
II	27·1	172	0·402
III	42·7	78·5	0·256

Volatility of the Oxides of Tungsten and Molybdenum in the Presence of Water Vapour

According to L. Wöhler and O. Balz[1,2], the oxides WO_3, W_2O_5 (W_4O_{11}) and WO_2 volatilize considerably above 800–900° C., and the vapour pressure of tungsten trioxide is, according to O. Ruff and Grieger[3,2], 0·206 mm. at 1,023° C. It is generally believed that this phenomenon explains the formation of much larger metal grains during the reduction of tungsten trioxide in hydrogen at 800–900° C. from much finer oxide grains.

Our experiments have, however, shown that the known oxides, WO_3, W_4O_{11} and WO_2, do not sublime at an appreciable rate under 1,000° C. either *in vacuo* or in a stream of a neutral gas. For example, 0·5 gm. of any of the oxides in a quartz tube at a pressure of 1/1,000 mm. gave only insignificant traces on the cold part of the tube during 58 hr. at 1,000° C., and only 1–5 mgm. during 8 hr. at 1,300° C. Similarly, less than 0·5 gm. volatilized at 1,000° C. during 1 hr. of the same quantity of WO_3 in a stream of oxygen (velocity 100 l./hr./2 sq. cm.) and an even smaller quantity of W_4O_{11} or WO_2 in a stream of purified argon (velocity 10 l./hr./2 sq. cm.).

The known oxides of tungsten volatilize, however, readily at 1,000° C. at a pressure of 1 atm. in the presence of water vapour (see Table 1).

This table clearly indicates that, under these conditions, the sublimation of WO_3 in moist air, oxygen

Table 1

1 atm., 1,000° C.							
	Carrier gas	Water (vol. %)	v, streaming velocity (l./hr./2 sq. cm.)	Time (hr.)	Weight of oxide (mgm.)	m, sublimed mass (mgm.)	k
WO_3	Oxygen	0	100	1	470	0·3	—
		0·4	100	1	490	1·2	30
		2	4	1	460	1·6	40
		29	113	1	470	120·6	39
		75	40	1/2	480	70·5	30
		100	30	1/2	470	81·3	30
W_4O_{11}	Argon	0	10	1	510	0·1	—
	Hydrogen	86	34	1/2	540	63·3	24
WO_2	Argon	0	10	1	330	0	—
	Hydrogen	59	41	1	140	39·6	37

or water vapour, of W_4O_{11} in a mixture of hydrogen and water containing 64–94 per cent water, and lastly of WO_2 in a mixture of hydrogen and water containing 49–64 per cent water (both mixtures assuring an invariant composition of the W_4O_{11} and WO_2 respectively[4]), is so rapid that during a few hours a substantial deposit would be produced. The speed of sublimation (the material volatilized in an hour) can be expressed with the notation of Table 1 approximately as follows :

$$m = k \text{ (vol. per cent) } \sqrt{v}.$$

The deposited WO_3 is a greenish-yellow crystalline powder, the W_4O_{11} crystallizes mainly in violet needles, and WO_2 gives a gold-brownish mirror of metallic lustre.

Searching for similar effects with the oxides of other metals, it was found that water vapour is capable of enhancing—if only to a smaller extent—the volatility of molybdenum trioxide (MoO_3) also (see Table 2).

Table 2

	Oxygen, 1 atm.					
	Water (vol. %)	v, streaming velocity (l./hr./2 sq. cm.)	Temperature (t °C.)	Time (hr.)	Weight of oxide (mgm.)	m, sublimed mass (mgm.)
MoO_3	0	80	600	1/2	892	0·5
	66	59	600	1/2	880	8·5
	0	80	700	1/2	892	15·0
	66	59	700	1/2	870	92·3

The sublimation of the above-mentioned oxides is therefore interesting, for WO_3, the hydrate of composition of which, WO_3H_2O, decomposes entirely when heated to 300° C., in its solid phase is unable to combine with more water molecules at higher temperatures, but can, however, easily combine with the water present in the gaseous phase. This phenomenon cannot be regarded as a water vapour-distillation, because there is no liquid phase. It must be emphasized that it is the oxides themselves which condense from the gaseous phase and not a hydrate. So it seems that the water molecules can form bonds in the gaseous phase strong enough to dislodge the oxides from the crystal lattices. We are of opinion that the generally known tendency of the W^{6+} and W^{4+} ions to be octahedrally co-ordinated[5,6,7] with $O^{=}$ favours the formation of separate molecules (for example, $WO_3.3H_2O$, etc.) in the gas, in contrast with the distorted octahedrons found in their lattices[5,6].

This property serves to explain C. J. v. Nieuvenburg and H. B. Blumendal's observation[8], who have found that solid tungsten trioxide can be dissolved in water vapour near the critical region, at 380° C., at 275 atm. Similarly, the pneumatolytic origin of tungsten ores can be accounted for; and the suggestion of the dominant role of water vapour near the critical pressure appears superfluous, for these ores can be formed at atmospheric pressure, too.

The sublimation of the oxides of molybdenum and tungsten can be used for analytical purposes and for the purification of the oxides. Tungstates cannot be attacked by water vapour.

The above investigations clearly indicate that it is not the spontaneous volatility of the tungsten oxides, but the volatility induced by water vapour, which is the main factor of the phenomenon, thoroughly investigated in the incandescent lamp industry, that by reduction with hydrogen the fine tungsten trioxide gives a much coarser metal powder.

Mechanism of the Fischer Indole Synthesis

Sir Robert Robinson (private communication) has commented that our interpretation[1] of the cyclizations of mixed hydrazones may be more simply explained by assuming that the hydrazones may be hydrolysed initially in glacial acetic acid medium, and then the free phenylhydrazines and *cyclo*hexanones recombine to form the different tetrahydrocarbazoles mentioned (*loc. cit.*).

Although it has not been possible to investigate this criticism completely, nevertheless it has been found by us that, when the *o*-tolylphenylhydrazone of *cyclo*hexanone is cyclized in glacial acetic acid in the presence of phenylhydrazine, appreciable quantities of carbazole can be obtained after dehydrogenating the product.

This indicates that the above criticism is very pertinent, and that our interpretation is only one of the alternatives. Further investigation is in progress.

A Method of Mounting Filamentous Materials for Spectroscopic Examination in the Infra-Red

Spectroscopic examination of filamentous materials in the infra-red has hitherto been far from easy owing to the difficulty of obtaining a satisfactory specimen mount. A twisted bundle of filaments cannot be used, partly because the effective thickness of such a sample is generally excessive, and partly because the amount of radiation scatter which it produces is far too great. For nylon filaments these difficulties have been overcome by the use of the mount described here.

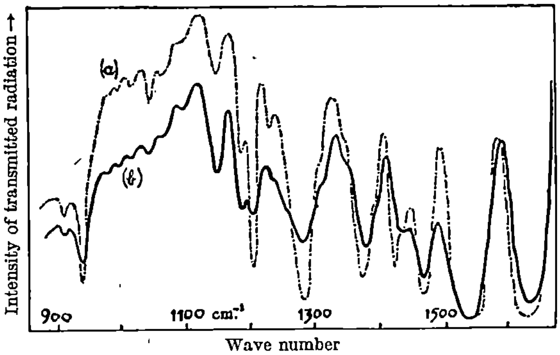
The device consists essentially of two rectangular U's, made from ⅛-in. carbon steel plate, between which is a strip of thin metal spacer foil, the plates being clamped together by means of two countersunk screws tightening into tapped holes in one of the plates. The gaps between the limbs of the U's are each ⅜ in., that is, slightly less than the length of the spectrometer slit. The inside faces of the plates are carefully ground and lapped flat so that they will stick together by mutual cohesion. The tips of the U's are given a slight chamfer so that the filaments may be inserted more easily. The thickness of the spacer foil should be one or two ten-thousandths of an inch less than the diameter of the fibres to be mounted.

In preparing a specimen it is convenient to clamp the mount to a glass plate and place it in the field of view of a binocular microscope. Single filaments, 4–6 in. in length, are then inserted one by one into the slots, bringing the first right up to the edge of the spacer metal and packing each succeeding filament as closely as possible to the last. Adequate packing can be obtained by inserting periodically a second strip of spacer metal into the jaws of the mount, using this to press the filaments closely together. Each filament can be held after mounting by embedding its ends in lumps of 'Plasticine' on the glass plate.

The number of filaments that must be mounted in this way will depend on their diameter and on the spectrometer slit width; for nylon filaments 0·008 in. in diameter it is sufficient to mount 40–50. When the required number have been placed in position, a final piece of metal foil is inserted to help preserve the alignment of the mounted filaments, and also to prevent any radiation passing directly into the spectrometer around the edges of the grid in the event of the specimen being moved while measurements are in progress.

The filaments are then stuck down to the outside edges of the steel plate by a thick cement, after which the cemented portion is covered with transparent adhesive tape. The loose filament ends and the protruding ends of the spacer metal are trimmed off.

The radiation scatter from the filaments so mounted is not excessive, and the effective thickness is low enough to allow reasonably small slit widths to be used, so that satisfactory spectra can be obtained from it directly. If desired, however, the scatter can be reduced by moistening the filaments with 'Nujol', and placing a small rock-salt window on each side, holding the windows in position by a small brass clamp.



A comparison of the instrumental records obtained from (*a*) a nylon film and (*b*) a grid of nylon filaments. (*a*) Nylon film, 20 μ thick; spectrometer slits 0·3 mm. (*b*) Grid of 20 μ diameter filaments: spectrometer slits 0·4 mm.

In the accompanying drawing, the transmitted radiation obtained from a filament grid (continuous line) is compared with one from a nylon film (broken line). For the grid, composed of filaments 20 microns in diameter, the spectrometer slits were set at 0·4 mm.; for the film, 20 microns thick, the slits were 0·3 mm. wide.

Measurement of Small Surface Angles

IT has been established that multiple-beam fringes of equal chromatic order are particularly sensitive for the evaluation of small surface angles. Yet they suffer from a disadvantage in that the angle shown by the fringes depends upon the orientation of the surface relative to the spectrograph slit. In fact, a resolved component of any surface angle appears, and in general it is necessary to rotate the surface under observation to find the maximum corresponding to the true surface angle.

This difficulty can be avoided by the combined use of superposition of fringes of equal chromatic order with Fizeau fringes, on the same photographic plate, as follows. Consider a simple wedge between two planes, one vertical with the edge perpendicular to the spectroscope slit. This leads to the formation of a family of fringes of equal chromatic order the shape of which depends upon the wedge angle and the spectrograph dispersion. If y_1 is the vertical distance between two fringes, then the wedge angle is $\tan^{-1} \lambda_1/2y_1$. However, in the general case the edge of the wedge is not perpendicular to the slit, and if φ is the angle made by the edge and the slit, then the true angle of the wedge θ is given by the relation $\tan \beta = \tan \theta \sin \varphi$, where β is the apparent angle given by the fringes of equal chromatic order, that is, $\tan \beta = \lambda_1/2y_2$, when y_2 is the vertical distance between two fringes. However, the Fizeau fringes from a wedge are straight lines parallel to the edge; hence the angle φ is simply the angle made by the Fizeau fringes with the slit, that is, with any spectral line. Clearly a superposition of the two systems enables φ to be measured.

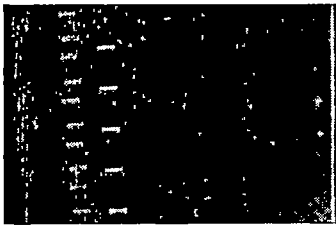

Fig. 1

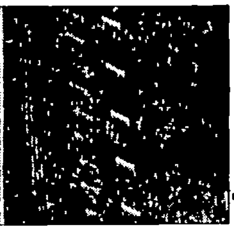

Fig. 2

This is obtained very easily in practice. The narrow fringes of equal chromatic order are first photographed with the usual source of white light, using a narrow slit. Without moving either the interference system or photographic plate, the slit is opened wide and the source of white light replaced by a mercury arc. Fizeau fringes are thus superposed on the fringes of equal chromatic order, as shown in Fig. 1. This is the special case of a wedge set with $\varphi = \pi/2$, and the Fizeau fringes are horizontal. The Fizeau fringes assist in identifying the intercept of a vertical line with successive fringes of equal chromatic order. In the case shown $\tan \theta = 0·001$.

Fig. 2 illustrates the appearance when the wedge happens to be set with $\varphi = 60°$, and it is easy to see how the formula given above enables θ to be derived. Even with such low dispersion, the angle calculated from Fig. 2 agrees with that from Fig. 1 to within about 1 per cent.

Quantitative Researches on the Optical Properties of Human Bone

THE quantitative studies of Dallemagne and Mélon[1] on the optical properties of ox bone (already described in part in *Nature*[2]), and their deductions concerning the relations between the organic and the inorganic fractions of the bone, have led me to a series of analogous, independent researches on human bone.

In specimens from subjects three to sixty years old, the index of refraction at room temperature of air-dried human bone (femoral diaphysis) was found to be almost constant and ranged around 1·560 ± 0·002. From birth until the age of three years, the index of refraction appears to rise at an increasing rate from 1·549 to 1·560. In the seventh and eighth decades, there is a small but noticeable increase: 1·564 ± 0·002. Bone from which the organic fraction has been removed shows a particularly interesting behaviour which to my knowledge has not been pointed out before: the index of refraction estimated by the methods of Becke and Schröder van der Kolke varies in value according to the nature of the comparison fluids. A value of 1·600 ± 0·002, almost constant for all ages, is obtained by using a mixture of oil of lavender and oil of cinnamon, which in all probability gives results more closely approximating the real values. Technical difficulties do not allow precise measurements of the index of refraction of fresh bone or of bone deprived of its mineral fraction. However, it is probable that the index of refraction of fresh bone from adult subjects is not less than 1·540.

The birefringent power of normal human bone ranges about + 0·004, as determined from measurements on seven subjects of 1, 3, 7, 11, 25, 50 and 80 years of age.

The quantitative researches clearly agree with the fact, already observed qualitatively by Schmidt[3], that normal human bone, deprived of its organic fraction, follows Wiener's law[4] of birefringence of form (*Formdoppelbrechung*). The parabolic curve of birefringence of form has a negative vertex. It follows from this that the mineral fraction of the bone is anisotropic and has its own negative birefringence (*Eigendoppelbrechung*). With due reservations on the more or less perfect penetration of the fluids in bone deprived of its organic fraction, the birefringent power of the mineral fraction is not constant, but varies with the age, tending to diminish rapidly in the first years of life, while remaining practically stationary during adult and old age.

The conclusions which Dallemagne and Mélon[1] wish to draw from their researches on the optical properties of ox bone, namely, "La fraction organique de l'os, représentée par l'osseine, n'accuse . . . aucun lien chimique perceptible aux méthodes physiques avec le phosphate tricalcique, élément principal de la fraction minérale", do not seem to me acceptable without reserve, and this for two fundamental reasons: (1) A chance coincidence may be responsible for the identical values obtained by these authors for the total birefringence measured directly and for the indirectly calculated birefringence. Indeed, the index of refraction and the relative volume of the organic substance measured by Dallemagne and Mélon do not apply only to the fundamental interfascicular substance (*Kittsubstanz*) to which the mineral fraction is bound, but rather to the complex mass consisting of fundamental substance + collagen fibres. (2) Dallemagne and Mélon also do not take into consideration the birefringence of the organic substance (fundamental substance + fibres), which certainly has an influence on the value of the total birefringent power of the bone.

Synthesis of γ-Glutamyl Peptides

IN the classical synthesis by Bergmann and Zervas[1], carbobenzoxy L-glutamic anhydride reacts with amino-acid esters to yield, after saponification and hydrogenation, α-glutamyl peptides. There have, however, been indications that the anhydride ring may not open exclusively in this direction. Bergmann[2] reported that glycylglycine ethyl ester yields a mixture of the α- and γ-derivatives, and in the analogous reaction with ammonia Melville[3] found some 14 per cent glutamine admixed with the *iso*-glutamine. Anomalies have also been observed in the opening of the ring of carbobenzoxy L-aspartic anhydride[4].

In the course of an investigation of ring openings of this type, we have examined the reaction of carbobenzoxy L-glutamic anhydride with cold aqueous hydrazine. The crystalline product, isolated in nearly quantitative yield (m.p. 170–171°), was found to be a mixture of the α- and γ-hydrazides, which could not be separated by repeated crystallization. Conversion to the azide and coupling with glycine ethyl ester gave a product from which carbobenzoxy α-L-glutamyl glycine could be isolated in low yield, but which on saponification and hydrogenation gave a mixture of α- and γ-peptides, since with ninhydrin 0·8 moles of carbon dioxide were evolved.

We were therefore led to prepare pure carbobenzoxy γ-L-glutamyl hydrazide by the action of hydrazine on the carbobenzoxy γ-ethyl-L-glutamate of Abderhalden and Nienburg[5]. This hydrazide, which clearly should provide an unambiguous path for the synthesis of γ-glutamyl peptides, has recently been described by Hegedüs[6], who has demonstrated its usefulness in a novel synthesis of glutathione. We record, however, m.p. 178–179° (uncorr.) for our carbobenzoxy γ-L-glutamyl hydrazide, which we obtained in quantitative yield on treating the ester with hydrazine in aqueous ethanol at 20° for 48 hours (found: C, 52·7; H, 5·9; N, 14·0; $C_{13}H_{17}O_5N_3$ requires C, 52·86; H, 5·81; N, 14·23 per cent. $[\alpha]_D^{18}$ − 13·4° ± 0·4° in 0·5 *N* hydrochloric acid, *c*, 6·4; $[\alpha]_D^{18}$ − 5·1° ± 0·3° in water containing 1 equiv. NaOH, *c*, 10·0). Hegedüs records m.p. 170–172° (uncorr.), and 44 per cent yield.

Our carbobenzoxy γ-L-glutamyl hydrazide yielded a benzylidene derivative, m.p. 200–201° (found: C, 62·5; H, 5·7; N, 11·2; $C_{20}H_{21}O_5N_3$ requires: C, 62·64; H, 5·52; N, 10·96 per cent). Conversion to the azide and coupling with glycine ethyl ester in chloroform solution gave carbobenzoxy γ-L-glutamyl glycine ethyl ester, m.p. 107–109°, which was saponified to carbobenzoxy γ-L-glutamyl glycine, m.p. 159–161° (found: C, 53·5; H, 5·3; N, 8·3; $C_{15}H_{18}O_7N_2$ requires: C, 53·24; H, 5·37; N, 8·28 per cent). Hydrogenation gave γ-L-glutamyl glycine, m.p. 193–194° (found: C, 41·5; H, 5·9; N, 13·7; $C_7H_{12}O_5N_2$ requires: C, 41·17, H, 5·93; N, 13·72 per cent. $[\alpha]_D^{14} + 11 \cdot 1° \pm 0 \cdot 8°$ in water, c, 2·5).

Partition chromatography on paper (using phenol saturated with water as the mobile phase) confirmed the purity of the γ-L-glutamyl glycine, in so far as only one component was revealed by ninhydrin. With the latter reagent at pH 2·5 and 100°, 1·0 mole of carbon dioxide was evolved, confirming the presence of a free α-amino-acid group.

These investigations are being continued and extended to the aspartic acid analogues. We are grateful to the Government Grants Committee of the Royal Society for financial assistance.

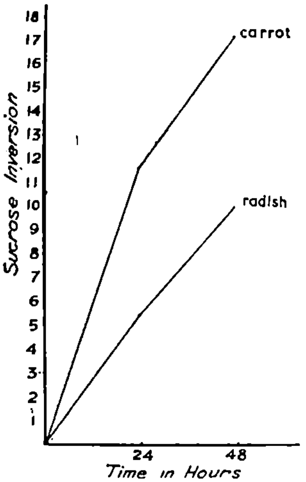
Comparative Study of Sucrose Inversion and Synthesis by Carrot and Radish Root Slices

In previous papers[1,2], it has been established that when radish or carrot root slices were suspended in sucrose solution, the latter was always inverted in the medium before its absorption by the tissue slices, and the inversion was always faster than the uptake, hence the accumulation of invert sugar in the culture medium. Gawadi[3] and Burström[4] showed that sucrose inversion takes place by means of invertase centres attached to the outer cytoplasmic surfaces of cells of the slices. Saïd[1] found that when slices of varied thicknesses were suspended in sucrose solution, the rate of inversion in the medium was directly proportional to the number of exposed surfaces per mass of tissue slices.



Total sucrose inversion in the culture media of equal numbers of carrot and radish root slices having the same diameter

We carried out several experiments in which 1-mm. thick slices of carrot and radish roots, having the same diameter, were suspended in sucrose solutions. Comparing the rates of sucrose inversion by equivalent numbers of slices of both roots, it was found that the rate of sucrose inversion by carrot slices was always much faster than that by radish slices (see accompanying graph). This observation leads to the conclusion that the number of active invertase centres on the outer cytoplasmic surfaces of radish is less than on equivalent surfaces of carrot.

Analysis of the sugar-fed slices from these two plants showed further that carrot slices always build up sucrose from any absorbed sugar whereas radish slices form but little sucrose from the absorbed sugars, the accumulation being always in the form of hexoses.

Coagulation of Oxalated Plasma Without Calcium Following Neutralization of Heparin by Toluidine Blue

Under physiological conditions, calcium is necessary for the coagulation of blood, because with thromboplastin it brings about the change of prothrombin into thrombin. But the true role of calcium ions has not hitherto been understood. On the other hand, this change is inhibited by heparin in connexion with a plasmatic co-factor, which was determined as an acid-soluble albumin[1]. The anticoagulating influence of heparin is specifically inhibited by toluidine blue[2]. We have used this property of toluidine blue to examine the function of the heparin which in normal circumstances is present in the blood. The influence of the physiological amount of heparin on blood coagulation is still under discussion. The complex heparin–plasma co-factor inhibits the action of thromboplastin on the change of prothrombin to thrombin[3]. We are putting forward the working hypothesis that the interaction between the heparin complex and thromboplastin of plasma is the cause of the fluidity of blood in the vessels, and that calcium in some way either with a tissue extract or otherwise neutralizes the heparin complex. If this assumption is correct, the toluidine blue will coagulate the decalcified plasma.

Oxalated pig plasma was used, and the point of coagulation determined in a water bath at 37° C. Toluidine blue was added in the isotonic Michaelis veronal buffer with sodium chloride in various concentrations. Fig. 1 shows the rate of coagulation of plasma induced by toluidine blue without recalcification. Further, we found that the clotting time under the influence of toluidine blue (curve *A*, Fig. 2) depends on the dilution of the plasma in a similar

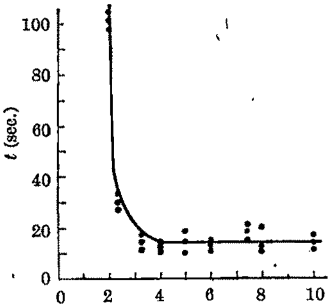

Fig. 1

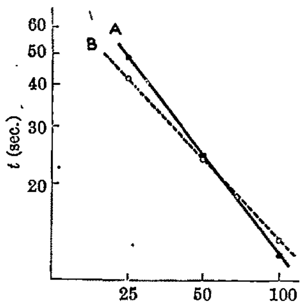

Fig. 2

proportion as in the case of the coagulation with thromboplastin and calcium (curve *B*, Fig. 2).

These experiments show that it is possible to produce coagulation of decalcified plasma without addition of calcium by adding toluidine blue only. The preformed plasma–thromboplastin is active enough to produce coagulation of the blood if the action of the heparin complex is inhibited by toluidine blue. The heparin present in blood takes part also in the blood-clotting process, and the role of that physiological amount of heparin seems to be to maintain the fluidity of blood in the vessels.

Nature of a Muscle-Inhibiting Compound in Lucerne and its Possible Connexion with Bloat in Cattle

IN an earlier note[1] attention was directed to the muscle-inhibiting power of clover juice and a possible relationship between this action and the disturbance known as bloat, or hoven, in cattle. Further work on a variety of herbage plant juices has confirmed the early findings[2], and has led to the separation from lucerne juice, purification and probable chemical identification, of a substance capable of inhibiting muscle movement.

Hydrocyanic acid can cause smooth muscle paralysis, and undoubtedly some acid is produced in the rumen of cattle grazing legumes, by the hydrolysis of cyanogenetic glycosides. South African workers[3], however, failed to incriminate hydrocyanic acid as a cause of acute bloat, but it should not be ruled out as one of possibly several aggravating or supplementing factors. This aspect has received attention at Aberystwyth[4].

The compound we have isolated from lucerne, by ether extraction of clarified juice, is a pale-yellow crystalline substance which, after repeated crystallization, strongly inhibits muscle action. Chemical and physical examination has shown it to be a flavone, and, subject to final confirmation by synthesis, it is most probably 3′, 4′, 5 trihydroxy, 7 methoxy flavone, a compound which, so far as is known, has not been previously reported as occurring naturally, although Kostanecki[5] synthesized it by reduction of tetramethoxy luteolin.

Flavones occur widely in plant material, presumably as glycosides, and quercetin, 3′, 4′, 5, 7 tetrahydroxy flavanol, for example, has been reported in white clover. Probably species and growing conditions determine the nature and quantity of the flavone present. Although a quantitative separation of the lucerne flavone could not be effected, there was little doubt that the young third-growth in August contained much less flavone than material grown earlier in the year.

Isolated muscle tests were made on thirty-four flavanoid compounds, most of them kindly supplied by Sir Robert Robinson. These all showed muscle-inhibiting action in concentrations between 1/200,000 and 1/50,000. The influence of various substituent groups in the flavone molecule could not be judged with any reliability, since varying, and generally slight, solubility affected the results.

Our knowledge of the pharmacological actions of the flavones is not extensive. They are reported as diuretics, cardiac stimulants and vaso-constrictors[6], and do not appear to be toxic. Their power to inhibit activity of isolated smooth muscle has been noted by Mahal[7]. They exhibit vitamin P-like activity, and rutin, a quercetin-rhamnoside, is being used therapeutically to decrease capillary fragility. The anti-oxidant action of vitamin P-like compounds towards adrenaline, which results in prolonged adrenaline effects on smooth muscle, have been confirmed with rutin, quercetin and the lucerne flavone, the rutin proving far less active than the flavones.

The significance, if any, of vitamin P in ruminant nutrition awaits elucidation, as also does the possibility of flavones playing some part in bloat. Some preliminary tests have been made on sheep, feeding a flavone with and without potassium cyanide. Nothing of note has been achieved in these tests, apart from some inhibition of rumen movements by the cyanide. One difficulty complicating these tests has been the relative insolubility of the flavone. However, the trials will be repeated in the spring when the animals are grazing and ruminant conditions more closely approach those obtaining when bloat occurs.

Myosin and Actomyosin Content of the Heart-Muscle

SZENT-GYÖRGYI[1-3] and his collaborators began their investigations on the contractile substances of muscle in 1941; my work on the myosin and actomyosin content of heart-muscle is mainly based on their results.

The extraction of actomyosin was carried out following the slightly modified method described by A. Csapó[4]. Pigs and rabbits were employed as experimental animals. The animal was bled to death, its heart taken out and cooled to − 12° C. The further experiments were performed in the cold room, at 0° C. Two 2-gm. portions of muscle were excised from the frozen right and left ventricle as well as from the auricle respectively; each specimen was ground in a mortar with 6-ml. Edsall's salt solution and sea-sand to a smooth paste. The actomyosin solution was centrifuged, decanted and allowed to stand for 24 hours at 0° C.; then its viscosity was estimated. The measurement was effected in the Ostwald viscosimeter at 0° C., the actomyosin solution having first been diluted with 9 volumes of pH7 veronal–acetate buffer. The viscosity of the actomyosin solution being thus determined, 0·1 ml. of 12 mgm./ml. adenosinetriphosphate solution was added, and then its viscosity measured again. From these two viscosities the myosin content and myosin–actin ratio was calculated, according to Straub and Balenovic. This ratio is expressed as a 'per cent activity' as Straub suggested. The myosin content, and the actin–myosin ratio of 1 ml. of an actomyosin solution extracted as described above, are given in the accompanying table.

	Left ventricle		Right ventricle		Auricle	
No.	% activity	mgm./ml. myosin	% activity	mgm./ml. myosin	% activity	mgm./ml. myosin
1	156	11·5	112	11·0	74	8·5
2	170	9·5	100	11·5	74	8·5
3	179	9·5	120	9·8	110	7·8
4	162	11·0	124	11·0	87	8·5
5	164	11·0	130	10·5	113	8·0
6	180	10·5	122	10·0	97	8·0
7	130	10·0	78	10·0	65	8·0

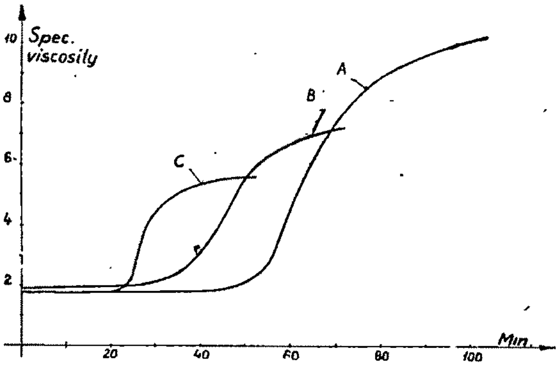
The values obtained, estimated by R. A. Fisher's method[5], give the following results. Average value of the differences between the myosin extracted from the ventricles and auricle respectively: $\bar{x} = 2\cdot3$; t (Student) $= 116\cdot0$; $P \ll 0\cdot001$. Average value of differences between the actin–myosin ratio of the right and left ventricle (expressed as 'per cent activity'): $\bar{x} = 50\cdot7$; $t = 10\cdot5$; $P \ll 0\cdot001$. The average value of differences between the actin–myosin ratio of the right ventricle and the auricle: $\bar{x} = 24\cdot0$; $t = 5\cdot75$; $P \ll 0\cdot001$. Since the P's are much less than 0·05, the lowest limit accepted in medical work, these three differences may be considered as statistically significant.

Experiments carried out on rabbit heart, expressed in the same manner, show the following values:

	Left ventricle		Right ventricle	
No.	% activity	mgm./ml. myosin	% activity	mgm./ml. myosin
1	90	7·0	55	6·8
2	160	9·0	64	8·8
3	120	8·0	56	8·8
4	140	8·0	77	7·8

Proceeding in the same manner as described above, we find that the average value of differences between the actin–myosin ratio of the right and the left ventricle is: $\bar{x} = 64\cdot5$; $t = 5\cdot28$; $P \ll 0\cdot001$. Thus the difference is significant.

My further investigations were extended to a modified Couette (torsion) viscosimeter also. The method was as follows. The actomyosin solution (prepared as described above) obtained from the left ventricle, right ventricle and the auricle of pig's heart was diluted with Edsall solution to about twice its volume, in order to have the same starting concentrations of myosin. The increase of viscosity, caused by the splitting of adenosine triphosphate, was recorded by the Couette viscosimeter, kept by a Hoeppler ultrathermostat constantly at 24° C. exactly. The values thus obtained are given in the accompanying curve. Specific viscosity is plotted against time.



A = left ventricle; B = right ventricle; C = auricle

The results show that there is a difference as regards the contractile proteins between auricle and ventricles, as well as between right ventricle and left ventricle. If we excise the same amount of muscle from the auricle as from the ventricles, we can extract less myosin from the auricle than from the ventricles. The left ventricle, accomplishing most of the work, contains more actin than the right one. The auricles, which do only regulating work, contain less actin than the ventricles.

Effect of 'Gammexane' on the Durability of Paper

THE use of 'Gammexane' has been recommended for controlling insect pests in libraries and record offices, where insect infestation is a serious problem especially in a tropical climate. 'Gammexane' smoke generators appeared to be particularly suitable for this purpose owing to the ease and safety with which they can be handled. But no information about its effect on paper[1] was available, and the use of a new insecticide for the disinfestation of documents of a unique and irreplaceable nature had therefore to be scrutinized from the preservation point of view.

No. 2 'Gammexane' smoke generators, weighing approximately 2 oz. each, were used at a concentration of 2 oz. per 1,000 cu. ft. as recommended by the manufacturers, Imperial Chemical Industries, Ltd., for insects infesting stored products. Samples of paper were exposed to the smoke for 72 hours in order to allow it to settle down completely, and care was taken to prevent any scorching effect from the smoke generator. Samples exposed to 'Gammexane' smoke were also submitted to accelerated ageing, which consisted in heating the samples for 72 hours at 100° C. The tensile breaking strength and the folding endurance of the treated and control samples were measured according to the standard TAPPI

(Technical Association of the Pulp and Paper Industry, New York) methods.

The mere exposure of paper to 'Gammexane' smoke brought about a substantial decrease in its tensile strength and folding endurance—as much as 53·7 and 71·5 per cent respectively in one instance. Papers exposed to 'Gammexane' and then submitted to accelerated ageing turned slightly yellow, and there was a complete loss of folding endurance in nearly all cases. All-rag hand-made paper of an extremely durable quality used for the repair of old manuscripts had a normal folding endurance of 4,164; but on exposure to 'Gammexane' smoke the retention of folding endurance was 28·5 per cent only, while on accelerated ageing the retention of folding endurance further decreased to zero.

The data obtained conclusively prove that treatment with the No. 2 'Gammexane' smoke generator is definitely injurious to paper records of all kinds and affects their durability as badly as acidic gases[2]. As the water through which the smoke had been bubbled was found to be distinctly acidic, it is almost certain that at least a part of the embrittling effect produced on paper[3] is due to the smoke-generating materials rather than to the 'Gammexane' itself. However, the gases obtained from the smoke generator No. 2 has a deleterious effect on paper, and it is advisable to prevent it coming into direct contact with paper records and manuscripts intended for permanent preservation.

The investigation is being followed up, and the details will be published in a subsequent issue of the *Indian Archives*.

Zoosporangia, believed to be those of *Plasmodiophora brassicæ*, in the Root Hairs of Non-cruciferous Plants

In 1936, during work on the cytology of *P. brassicæ*, zoosporangia identical with those of this well-known parasite were seen by me in root hairs of grass and dock seedlings, which had appeared in a pot of soil taken from a garden in which the club root disease of the Cruciferæ was a major problem. In view of the known persistence of *P. brassicæ* in soils without cruciferous crops, it was decided to attempt a crude cross-inoculation experiment using club root galls as a starting point. Suitable soil was partially sterilized by keeping it at 190° F. for one hour. Ten six-inch pots were filled with this soil, and club root galls with unbroken surfaces, but of an age known to contain mature spore masses, were cut up and placed in five of them. Brussels sprout seedlings germinated in these pots became infected, and an examination of the root hairs of the grass *Holcus lanatus* grown from seed with them in the re-infected soil revealed numerous zoosporangia and some free-swimming zoospores.

Twenty of these root hairs, which were, so far as could be seen, free from external debris of any kind, were placed in three of the remaining five pots of sterile soil, in which seedlings of brussels sprout were growing. In these three pots, ten of the twelve seedlings became infected, apparently with *P. brassicæ*, while in the two control pots the eight plants remained free from attack.

The root hairs were removed from the *Holcus* plants, after careful washing in distilled water, by sucking the end of the hair into a capillary of suitable size and gently tearing away the required portion. This was done without the aid of a micro-manipulation apparatus, and it is fully realized that it would have been preferable to transfer zoosporangia or zoospores alone. This was, however, not possible. The cycle of events in zoospore formation in root hairs appears to be identical, up to the point at which zoospore formation begins, with the normal cycle in cruciferous roots. The somatic mitoses, transitional phase and reduction division were all seen and were similar to those described for *Spongospora subterranea* by Horne[1] and for *Sorosphæra veronicæ* by Webb[2].

In July 1948 similar zoosporangia were seen by me in two root hairs of 'Auchincruive Climax' strawberry from Botley, Hampshire. Subsequent inquiry revealed that club root had been troublesome in the immediate vicinity.

Plasmodiophora brassicæ has been suspected of infecting plants other than the Cruciferæ on several occasions in the past, notably by Marchand[3] in 1910. The hypertrophy described in these accounts of the disease is now usually ascribed to nematodes, and reports of the presence of the *Plasmodiophora* are treated with great reserve. Marchand[3] saw what he believed to be *Plasmodiophora* in melon, celery and "oseille-epinard", which latter is believed to be a dock, *R. patientia*; but the spore diameter in melon was twice that of *P. brassicæ* in crucifers, and the identity of the parasite is thus open to doubt.

In view of the present methods of control of club root, it is highly desirable that the identity of the zoosporangia I have seen, and the specificity of *P. brassicæ*, should be established by cross-inoculation experiments using all possible precautions to ensure sterility.

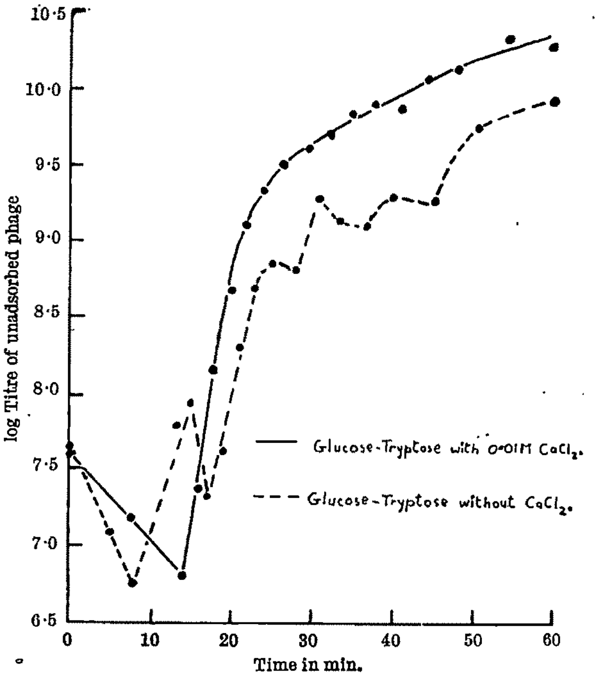
Multiplication of Coliphage at High Concentration

The 'single-step' method devised by Ellis and Delbrück[1] has proved of immense value in the hands of a number of workers in studying the multiplication of various bacteriophages; but it was devised specifically to investigate the behaviour of bacteria and adsorbed phage at high dilution, and gives no direct information about the more complex situation normally occurring, when phage released by lysis of one bacterium can interact further with other bacteria. Since this information was necessary for a line of investigation we are pursuing, and since, moreover, it might prove of more general interest, we have devised the method described below.

Escherichia coli, strain *B*, is grown in a medium consisting of 2 per cent Bacto Tryptose, 0·2 per cent glucose and 0·5 per cent sodium chloride for $2\frac{1}{2}$ hours at 37° C., by which time the viable count is 50–70



million organisms per ml. Coliphage T_2 is then added to produce a final concentration of about fifty million lytic units per ml., and aliquots removed at intervals for assay. These are diluted several hundred times into 0·85 per cent saline containing 0·01 *M* phosphate buffer, *p*H 7·0, maintained in an ice-water bath (slow release of phage from the bacteria occurs at room temperature), and then the diluted mixture centrifuged in an angle centrifuge at 3,500 r.p.m. for 10 min. to remove bacteria and adsorbed phage. An aliquot of the supernatant is further diluted in phosphate-saline and assayed by the plaque-counting method of Hershey, Kalmanson and Bronfenbrenner[2]. From these estimations a curve is obtained giving the titres of unadsorbed phage in the original mixture at various times.

An example of the application of the method is given in the accompanying graph, which illustrates preliminary experiments on the effect of calcium ions on the release of phage from the bacteria. Calcium is known to have a marked effect on the multiplication and plaque formation of phages[3,4,5], but no attempt seems to have been made previously to follow the course of adsorption and lysis in its presence. As the graph shows, 0·01 *M* calcium chloride causes a marked alteration in the form of the curve: in the ordinary medium, multiplication of phage proceeds in a series of stages of adsorption and release, each stage occupying the same time for all bacteria infected simultaneously, so that the graph shows a series of sharp peaks and hollows; in contrast, release of phage and re-infection of further bacteria in the presence of calcium appears to occur in random fashion after the initial adsorption period, the multiplication appearing as a smooth increase in the titre of unadsorbed phage. A number of other points of interest also emerge from these experiments: (1) both in the presence and in the absence of calcium, adsorption of phage on to the bacteria continues logarithmically up to the time when lysis begins; (2) the latent period before lysis commences is lengthened from 8 min. to 14 min. in the presence of calcium; (3) while the experimental curves for adsorption and lysis in the presence of calcium are readily reproducible in other experiments, in its absence only the points of inflexion at 8–9 min., 15–16 min. and 17–19 min. can be reproduced, the later stages being extremely variable; (4) the final titre at 60 min. is invariably higher in the presence of calcium; and (5) the turbidity of the culture is always greater after lysis with calcium in the medium.

The significance of these findings, taken in isolation, is not clear. But the results of other experiments (to be published later) on the effect of enzyme inhibitors on phage multiplication indicate that the calcium ions also probably have an inhibitory effect on one of the enzyme systems of the bacteria.

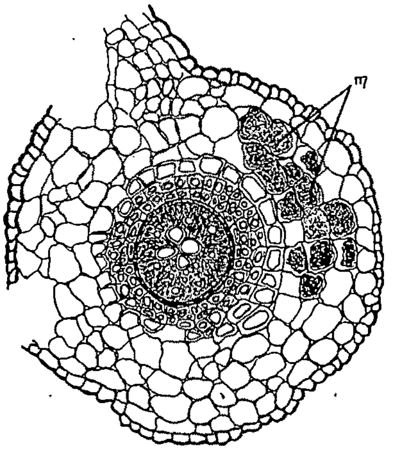
Occurrence of Endotrophic Mycorrhiza in the Roots of *Pteridium aquilinum* Kuhn.

Although Stahl[1] believed that *Pteridium aquilinum* was one of the completely autotrophic ferns, later workers[2-5] have reported the presence of an endotrophic mycorrhiza, and Truszkowska[5] described an endotrophic mycorrhiza in the roots of *Pteridium aquilinum* in Poland which he found growing in soil of *p*H 4·4.

A mycorrhizal condition in roots of bracken in Scotland was demonstrated by Alcock in 1927[2]. Recently, it has been found in two areas in the west of Scotland, where (as Alcock had previously found) it seems to occur irregularly, but possibly more often than was at first realized. The two areas are: (*a*) Drumclog Moor, Milngavie, Dumbartonshire, where roots with mycorrhiza were found in March, April, May and July. The soil was peaty with much humus and had a *p*H of 4·4, a point that agrees with



Transverse section of the root of *Pteridium aquilinum* showing the mycorrhizal layers of cells in the middle cortex. (Camera lucida drawing, × 55)

Truskowska's observations. (*b*) Horticultural land near Auchincruive, Ayr, where roots with mycorrhiza were found in July. The soil was a loam of *p*H 7·7.

Many of the roots of *Pteridium aquilinum* in both these areas were quite unaffected; but those with mycorrhiza were rather fleshy and larger than the others. These features were by no means regular and were not an infallible guide to the presence of the fungus. It has not been seen in the roots of young plants, but such young roots as have been examined were those of cultivated plants.

The accompanying drawing shows the endotrophic mycorrhiza occurring irregularly in the cortical cells of the root. In some cases, the apices of the hyphæ showed small swellings which may be similar to the 'sporangioles' mentioned by McLennan[3]. The fungus was found in the middle cortex, and the thickened cells of the inner cortex showed little infection. It has been seen in several layers of cells and not confined to one cortical layer as described by Rayner for *Aspidium filix-mas*[3]. No special digestive zone could be distinguished.

It is probable that the presence of such an endotrophic mycorrhiza is more widely spread among bracken plants than is at present appreciated.

Effect of Sulphanilamide and *p*-Aminobenzoic Acid on Mitosis

THE action of sulphanilamide on plant growth shows many parallels to its action on bacterial growth. As Bonner[1], and more recently Audus and Quastel[2], have shown, sulphanilamide will completely abolish growth in length or wet-weight of roots. This inhibition, as in bacteria, is competitively reversed by addition of *p*-aminobenzoic acid to the nutrient solution. Audus and Quastel, however, are of the opinion that the competitive reversal is of a different nature in root growth from that in bacterial growth. Their evidence for this statement is based on the fact that, while in bacteria reversal is complete even with a *p*-aminobenzoic acid concentration 1/50 to 1/4,000 that of sulphanilamide, in roots reversal is complete only when the ratio of sulphanilamide to *p*-aminobenzoic acid is approximately unity.

Plant growth as measured in these experiments is, however, a rather more complex process than bacterial growth, in that the bulk of growth in length or wet-weight is the result of expansion of cells by uptake of water. The amount of 'growth' caused by cell division in the meristems is only a small fraction of the total increase in volume or wet-weight. It seems necessary to attempt a separation of these processes before discussing the mechanism.

The action of sulphanilamide on mitosis in plant cells has been studied by several investigators[3,4,5]. Sulphanilamide appears to have two actions: (1) At concentrations of 0·1–0·5 per cent it stops nuclei coming into prophase, so that there is a fall in number of dividing cells. From experiments on the lateral roots of onion, the number of mitoses is reduced to 0–15 per cent of the original number, after forty-eight hours. (2) In those cells which do begin to divide, the spindle mechanism is upset so that the anaphase movement rarely, if ever, occurs. As Peters[4] has shown, this leads to the formation of tetraploid cells, the arrested cells with scattered metaphase chromosomes without a spindle gradually lapsing back into a resting stage, thus simulating the action of colchicine.

During the last two years, I have been investigating sulphanilamide inhibition, in an attempt to find whether these effects are reversed by application of *p*-aminobenzoic acid. Both effects appear to be reversible. The accompanying table indicates the kind of result obtained in an experiment in which the *p*H of all solutions was about 4·0.

	Prophase	Metaphase	Anaphase Telophase	Total
Control	290	112	113	515
Sulphanilamide	29	9	1	39
Sulphanilamide/ *p*-Aminobenzoic acid	315	58	59	432

Results of different experiments have varied, and the reversal is not as a rule complete. The numbers for anaphase and telophase have always been less than in the controls, although the divisions which do occur seem to be normal.

In preliminary experiments on the effect of *p*H on reversal, it has been found that at *p*H 7·0 reversal is far less complete than at *p*H 4·0. Possibly this is simply due to ionization and permeability effects, and the different results obtained with bacteria and higher plants may be due to such relationships.

I wish to express my thanks to Prof. A. Burges and Prof. H. N. Barber for advice.

Occurrence of *Acanthocephalus ranæ* Schrank in Great Britain

RECENTLY, Dales[1] and Eales[2] recorded the occurrence of *Acanthocephalus ranæ* Schrank in Great Britain. Three specimens of this species were discovered during routine dissection of *Rana t. temporaria* L. this session, and a further eight specimens in the departmental collection have been examined. Of the latter, seven were taken from *Bufo b. bufo* (L.) and one from *R. t. temporaria*. A summary of the ten specimens is given in the accompanying table.

The numbers of rows of hooks and number of hooks per row were counted after making camera lucida drawings. As the proboscis was not fully extended in all the specimens, it was not always possible to be absolutely certain about the numbers.

In this Department, an average of twenty-four *R. temporaria* were carefully examined each year from 1927 until 1939 for metazoan parasites. During that time only one *A. ranæ* was found. Further, one of us (H. R. H.) examined the gut of several hundred *R. temporaria* of British origin (exact locality unknown) during the years 1922–24. No specimens of

Number of longitudinal rows of hooks	Number of hooks per row	Total length in mm.	Sex	Host	Locality	Remarks
—	–	approx. 5	♀	*Rana t. temporaria*	Norwich, Norfolk	Specimen lost before detailed examination. Collected Dec. 1948
12	6	5	♀ (gravid)	,,	,,	Collected Dec. 1948
14	6	5	♂	,,	,,	Collected Oct. 1948
13	6	4·5	♂	*Bufo b. bufo*	Amersham, Bucks	
14	6	4·5	♂	,,	,,	
14	5	2·5	♂	,,	,,	Toads collected by Lancelot Hogben, Oct. 1921.
14	5	5	♀ (gravid)	,,	,,	
14	5	3	♀ (gravid)	,,	,,	Specimens of *A. ranæ* prepared by H. R. Hewer when a student
14	5	3	♂	,,	,,	
14	5	2·5	♂	,,	,,	
12	5	4	♂	*Rana t. temporaria*	Newdigate, Surrey	Collected Oct. 1930

A. ranæ were found, although many contained numerous other helminth parasites.

All the specimens recorded above are comparatively short. The samples from *R. temporaria* are too small to be significant. Those recorded from *B. bufo* were not the only specimens found on that occasion. Two or three other members of the class each found a similar number of specimens, all of which were of about the same size. It is possible that *A. ranæ* does not reach the same large size in *B. bufo* as it does in *R. temporaria.*

It appears probable that the distribution of *A. ranæ* in Britain is local; but that where it is found it may be abundant. Obviously, Dales is correct in suggesting that its apparent rarity is due to lack of recorded observations.

Nomenclature of Polymyxin Antibiotics

Polymyxin is a term introduced by Stansly, Shepherd and White[1] for an antibiotic substance elaborated by *Bacillus polymyxa.*

Brownlee and his colleagues[2,3] independently reported the discovery, from a different strain of *Bacillus polymyxa,* of an antibiotic designated as 'Aerosporin' which appeared to be similar to 'polymyxin' in its antibacterial spectrum, but to exhibit certain different pharmacological properties[3]. Evidence has recently been obtained[4,5] which confirms that 'polymyxin' differs from 'Aerosporin' both pharmacologically[6,7] and chemically[4,5]. Furthermore, it is now known that different strains of *Bacillus polymyxa* are capable of producing a number of related antibacterial substances which differ chemically[4,5] and pharmacologically[6,7] one from the other.

In view of these circumstances, it appeared advisable to unify the nomenclature of this group of antibiotics in order to emphasize the relationship of the members of the group and to avoid the publication of an array of bizarre names which would only confuse it. This end has been achieved by agreement on 'polymyxin' as the generic term for these antibiotics, the individual members being polymyxin A, B, C, D, etc.

At the present time the known polymyxins may be characterized as basic antibacterial polypeptides, the salts of which are water-soluble, having a unique specificity for the Gram-negative bacteria. The known members have, in common, α,γ-diaminobutyric acid, threonine and a branched C_9-fatty acid as molecular constituents[4,10].

Polymyxin A is the name given to 'Aerosporin'[2]; in addition to L-threonine and L-α,γ-diaminobutyric acid, it contains D-leucine[10]. Polymyxin B contains both leucine and phenylalanine as additional constituents, whereas polymyxin C contains only one additional amino-acid, namely, phenylalanine[5]. Polymyxins B, C and E, the product of distinctive strains of *Bacillus polymyxa*, have recently been announced from the Wellcome Research Laboratories[5,8]. Polymyxin D is the main active component of the material described from the American Cyanamid Company[1,4,11] and contains D-leucine and D-serine in addition to the common constituents[4,5]. Polymyxin E contains the same constituents as polymyxin A, but is distinguished from the latter by partition chromatography on paper[8]. The fatty acid of the polymyxins has been described but not fully characterized. It appears to be the same in polymyxins A, B and D[4,10].

Attention is directed to the fact that no implication of priority is to be attached to the sequential assignment of letters. Assignment of letters to further antibiotics in the series should be based solely on published data which characterize the antibiotic as a new member of the polymyxin group.

AIR SAFETY

It is a maxim of aircraft design and operation that economics and safety are complementary factors, and that it is always possible to achieve a favourable financial return by ignoring safety considerations, whereas too great a concentration on safety tends to result in economic failure. It is in the achievement of a fine balance of the two factors that the skill and ability of the efficient designer and operator manifest themselves.

This maxim was, no doubt, very much in mind, although never stated, at the all-day discussion on air safety held by the Royal Aeronautical Society on March 5 at the Institution of Civil Engineers. Four papers were presented covering different aspects of the problem, but few significant advances of scientific interest were revealed.

The first paper, by Mr. J. D. North, was on "Some Aspects of the Relationship between Airworthiness and Safety". In this paper, Mr. North brought some of the concepts of philosophy and psychology to bear on the problem. Starting with the conception of 'net yield' (being the difference between 'gross' yield and a somewhat indeterminate quantity 'damage'), he analysed the factors involved in the various terms, the principal ones being the environment, the human factor and the type of aircraft. The method of analogy provided the main approach, and his analogy was that of a game having the nature of patience or solitaire, the object of the game being to move along a grid containing several hazards and to lose the minimum number of points, the optimum path representing the time–space motion which gave the minimum damage. Statistically there is no doubt some basis for such an analogy; but the discussion indicated a certain lack of appreciation of Mr. North's methods and objectives. Apart from criticism of the vagueness of the term 'damage'—which, when interpreted as loss in prestige as well as material loss, may well alter the framing of the initial concept—one of the chief objections to the analogy is that it is unnecessary to import into the science of aeronautics unfamiliar methods and notations which lead eventually to results derivable far more simply by the usual methods. Indeed, there was great doubt as to whether more than a tiny percentage of those present at the discussion understood Mr. North's paper.

The second paper, on "The Physiological Aspects of Air Safety", was read by Dr. K. G. Bergin. The advances in the field of aviation medicine at the present time are naturally associated with the advances of aviation generally. Particular points of interest are the effects of high accelerations and decelerations, high-altitude effects, low-temperature effects, effect of vibrations, and the toxic effects of fumes. All these are, however, problems which arise principally in military aircraft, and so it was a much more restricted field of rather less interest that was covered by Dr. Bergin, who dealt with questions occurring during normal civil operations.

Referring to the question of vision, Dr. Bergin stated that the average percentage decrease in range of night vision varies linearly with altitude, being 5 per cent at 4,000 ft. and 35 per cent at 16,000 ft. Other factors reducing night vision include glare, lack of oxygen, smoking, alcohol, inadequate vitamin A, and fatigue. Suitable precautions can always be taken to ensure that diminution in visual acuity is not dangerous, particularly since the effect is temporary. A more serious problem is the permanent and irreversible deterioration in hearing, known as aviation deafness, resulting from the constant bombardment of the ear by noise over a period of time. The trouble is progressive, starting with a reduction of auditory acuity over the high-frequency range and eventually including the low tones as well. Lack of oxygen is a great potential source of accidents, since it results in false impressions of the pilot's own capabilities, a diminution in skill, speed of reaction and accuracy of attention to detail. The vision is also affected, particularly the power of accurate focusing and optical convergence.

On the question of equilibrium, Dr. Bergin described three common disorders: the autokinetic illusion, the oculo-gyral illusion possibly complicated by autokinesis, and the oculo-gravic illusion. The first of these consists of the apparent movement of an object when viewed against a dark background in the absence of spatial localization. The condition is dangerous only if it occurs at a critical moment. The second illusion is due to conflicting impulses from the eye and the semicircular canals in the part of the ear known as the labyrinth, which, following angular acceleration, results in the apparent movement of objects. The third illusion is due to conflicting impressions between the eye and the otolith organ, and, following accelerations, consists of an apparent displacement of an object in space. The effect of the illusions can be eliminated by blinking, by the use of flashing lights instead of steady lights, or by the use of a number of non-planar lights.

The elimination of fatigue of personnel is important in accident prevention, since fatigue can result in diminished nervous impulses, slowed reactions, impairment of judgment, vision and hearing. Dr. Bergin emphasized the necessity for proper rest for the pilot between flights, adequate diet, and good conditions inside the cockpit. The latter should include proper seating, good windshield design, correct positioning of the instruments and controls, and good insulation. By great care of the health of the crew the risk of accidents can be diminished, and thus the medical aspects of aviation are of fundamental importance.

The third paper, by Capt. J. W. G. James, was entitled "Air Safety from the Pilot's Point of View". His paper was, of necessity, more concerned with the human element than with a scientific approach. He dealt with most of the current difficulties encountered by pilots, in particular stressing the need for better control-cabin layout and good handling characteristics (involving light controls, rapid response, low safety speed, stability, and no change in longitudinal trim during flap and undercarriage movement). The importance of proper training for pilots in order to achieve a high standard of technique, particularly in instrument flying, cannot be overstressed, and Capt. James expressed very definite views on this point. He also advocated the use of a medical service for maintaining health—as distinct from its use as an examining body—which at the moment is the function of the Ministry's medical service. He was somewhat critical of the present conception of 'flying hours' as a criterion for pilots' efforts, and suggested that an 'hours on duty' restriction may eventually be introduced. He felt, however, that all restrictions of this type could be more easily handled by the co-operative effort of the pilots and operators. On the question of operating technique, Capt. James laid down recommended procedures and suggested that the use of drill cards for checking their implementation is desirable. The procedures, although of interest and conducive to increased passenger comfort, would not seem to increase the inherent safety of operation. He deplored the lack of standardization of air traffic control systems—some five are in common use—and expressed the view that such variations tend to decrease safety owing to the excessive practice required to maintain efficiency. The subject of accident investigation—about which much was said in the later discussion—has always been of particular interest to pilots, and Capt. James stressed the importance of this, since only by adequate representation of pilots on investigating committees can the stigma of pilot's error be avoided. (A rather interesting point raised in the course of the discussion was that the term 'pilot's error' might well be replaced by 'designer's error', since the possibility of guarding against possible mistakes in operation can well be regarded as the designer's responsibility.)

The last paper, presented by Dr. G. E. Bell, was entitled "Operational Research into Air Traffic Control". This paper was concerned with experimental investigations (including time and motion studies of take-off and landing, studies of air/ground communications, and an analysis of the traffic and traffic pattern in south-eastern England) and with theoretical investigations into the problem of traffic congestion. The quantitative data on the distribution of delay times was extremely enlightening. In August 1948, at London Airport, about 40 per cent of the incoming aircraft were held for an average time of rather less than 10 min., the average holding-time for all aircraft being some 3½ min. At Northolt, where the loading is heavier, the corresponding figures are 65 per cent held for an average of 16½ min. with an overall average of 10½ min. Approach times vary between 6 and 15 minutes, whereas runways are occupied for between 8 and 9½ minutes for each landing. Thus landing delays are considerable, and the necessary stacking increases the risk of collisions. Dr. Bell presented an analysis of the traffic congestion problem on the assumption of a constant holding-time and based on considerations of statistical equilibrium. He showed that by a knowledge of the 'expectancy' ε, or average number of arrivals in the holding time T, and of the values of the arrival probabilities, the probable degrees of congestion can be estimated. Assuming the Poisson distribution of probabilities, the mean delay is given by

$$t = \frac{1}{2} \frac{\varepsilon}{1 - \varepsilon} T.$$

The effect of deviations from stipulated fixed intervals of arrival was also considered, and it was found that the improvement of a scheduled arrival-rate over a random one is only marked when the standard deviation is small compared to the scheduled interval.

He concluded by pointing out that the capacity of an airport is seriously affected by the 'holding time'; thus at a factor of 0·8, a 10 per cent reduction in holding time increases the capacity and reduces the average delay for the same congestion by some 10 per cent. The most promising approach to reduced holding times is the greater use of radar control.

Much can be said of the value of the day's discussion, but undoubtedly the contribution to the subject of 'air safety' was very limited. Too many gaps were left to regard the meeting as satisfactory. The attitude of the designers and the official regulating body (the Air Registration Board) only slipped in during the general discussion following the papers, instead of being adequately covered by formal statements; and it is a great pity that too much time was spent by the principal speakers on matters outside the scope of the day's proceedings, and too little on the fundamental requirements for an improvement of 'air safety'. HENRY ROBERTS

BRITISH HYDROMECHANICS RESEARCH ASSOCIATION

THE British Hydromechanics Research Association was officially incorporated on September 20, 1947, as a company limited by guarantee, and at the first annual general meeting held a month later Sir John Anderson was appointed president, and a council of ten elected. In the Association's first annual report, which has recently been issued, a review is given of the progress during the period October 1947–September 1948. Mr. L. E. Prosser was appointed director of research in April 1948, and a small staff was recruited later in the year. Thirty-one manufacturers of hydraulic and related machinery are members of the Association, and the associate members include twelve firms of consultants and twenty professors and academic workers. Although directly controlled by industry, the Association operates under the ægis of the Department of Scientific and Industrial Research, and it is hoped that, in the very near future, with adequate support forthcoming from industry, the Association will qualify for a Government grant.

The aim of the Association is to promote original research in hydraulics, and in the application of scientific principles to the manufacture and use of hydraulic machinery and equipment. In this connexion it acts as a liaison between industry and university and Government research laboratories. An efficient information service is being built up to collect and disseminate to the members technical information on hydromechanics and related topics. There is a need for an abstract service covering current publications on hydraulic science, and the *Bulletin* of the Association should prove very valuable in this respect. The first number of the *Bulletin* appeared at the end of 1948, and its contents include a selection of non-critical abstracts arranged in accordance with the universal decimal classification, Association news, and book reviews.

Six sectional research committees, dealing with fundamental fluid mechanics, measurement and laboratory technique, pumps and turbines, control and motion of fluids in pipes and valves, seals and joints, and reciprocating machinery, have been set up. The names of the members of these committees and the subjects under consideration are listed in the annual report. There is little doubt that the Association can become invaluable to the hydraulic industry of Great Britain, and, as Sir John Anderson points out in his foreword to the report, "the formation of this new Research Association is more significant than its present modest development would indicate, as it represents a further step towards a closer relationship between Government and technical interests of industry".

TEMPERATURE MEASUREMENTS IN ECOLOGICAL ENTOMOLOGY

By W. G. WELLINGTON

Forest Insect Laboratory, Sault Ste. Marie, Ontario

MUCH research in ecological entomology is concerned with the effects of temperature upon insects. Nevertheless, there is still some dissatisfaction with instruments or methods employed to measure temperatures for entomological purposes. Difficulties are often encountered in projecting laboratory data to field situations, or in attempting to reverse this procedure, and it is admitted that the numerous special methods for registering air temperature outside standard shelters yield figures which are, for some purposes, no more closely associated with an actual habitat than are shelter temperatures.

It is known that the marked differences observed between the temperature of the air and that of individual parts of both plants[1-3] and insects[4-7] result from radiant heating or cooling as well as from moisture transfers. At least so far as radiant heating is concerned, the temperature differences produced may be so large that, when they occur, continuous records of air temperature are of little value for connecting the results of laboratory and field observations. Thus, it seems time to pay some attention to means of obtaining more useful temperature records.

Such temperature differences as have been demonstrated have been measured chiefly by thermoelectric means. However, indicating potentiometers are limited in usefulness by the fact that they give only instantaneous measurements; and, for general field use, there is a great need for simpler and less expensive recording equipment than power-dependent recording potentiometers.

Both the plant habitats of insects and insects themselves behave more or less like black bodies. This being so, it would seem profitable to investigate the uses of thermometric equipment modified so that it may absorb or emit radiation freely. This approach requires some changes in our attitude towards thermometry. Hitherto, although entomologists rejected the instrument shelter which attempts to standardize radiational errors in temperatures measured for synoptic or climatological purposes, they have assumed the attitude of meteorologists towards the exposure of instruments to radiation. Thermometer bulbs and thermograph bimetals are still shielded or polished 'to minimize undesirable' radiation effects. While there are very sound reasons for this when air temperatures are involved, in situations where plant or insect temperatures may differ by 5–20° C. from ambient temperatures, what is the point of measuring air temperature? It would seem preferable to try to make some of the existing instruments as similar as possible to the natural bodies and to expose them to equivalent conditions. Admittedly, there are some recognized objections to this procedure, which are based on varying heat capacities and on the blunt statements that no measured temperature is what one thinks it is; but the technical difficulties are not insurmountable if thinking is directed along lines differing from the accepted approach. More often than we realize, the chief interest of an ecological entomologist in radiation is in its temperature effects, not in its intensity. Wider recognition of this might diminish the numbers of ingenious adaptations of precision thermopiles and bolometers, from the records of which ecologists laboriously convert the heating or cooling effects of radiation—which are what they need—into units of radiation—which they can seldom apply. Furthermore, to obtain these records, the instruments are carefully shielded from air temperature and movement which act constantly upon the natural 'black bodies'.

Recent tests of a modified thermograph at this Laboratory have shown promise. During tests of the effects of radiant heating upon the foliage of *Abies balsamea* Mill. under field and laboratory conditions, it was noticed that blackened thermocouples or junctions attached to blackened aluminium disks reached the same temperatures as did the interiors of closed or expanded buds, or of enclosed tortricid feeding chambers. On the other hand, these special junctions were better 'black bodies' than the individual needles, but less efficient than staminate flowers. These junctions were matched, and while similar temperatures were recorded at the points noted above, consistent differences were recorded between the flower and vegetative buds and between all foliage and the surrounding air, so that the similarities observed did not result from peculiarities of the junctions. When field observations were extended to other tree species (*Picea glauca* Voss, *P. pungens* Engelm., *Pinus Banksiana* Lamb. and *Populus tremuloides* Michx.), the relationships were found to hold among coniferous species and, while normal aspen leaves were not equivalent to black surfaces, the temperatures of air spaces enclosed by leaves rolled or tied by tortricids were equivalent to those of the surfaces. Finally, the bimetal of a thermograph was blackened and the instrument was exposed beside the trees and the disks. Close agreement was obtained among the temperatures of the buds, shoots, tunnels, disks and bimetal under conditions of uniform exposure. The thermograph pen, of course, often recorded fluctuations amounting to 5° C. in sunlight, but, at such times, the foliage temperatures moved through the lower third of this range very consistently, or, at worst, fell 1° below it momentarily. At the same times, air temperatures ranged up to 6° lower than the foliage. In the absence of fluctuations, foliage and bimetal temperatures were equivalent or within 0·5°, while the air temperature was still too low.

The fact that a black paint ('Drop Black Enamel') chosen at random and applied to a bimetal produced temperatures in far better agreement with bud or enclosed air-space temperatures than were air temperatures, suggests that this approach is worth further investigation by interested workers in a position to test instruments under more varied conditions than are available within the present narrow limits of altitude and latitude. Such tests seem worth while even when it is to be expected that treated bimetals cannot record temperatures similar to those of great numbers of plants or insects since, as noted above, discrepancies appeared in tests of staminate flowers or of individual needles of one species.

During the preliminary tests, at least an indicating potentiometer and thermocouples are essential for establishing the relationships. Any weatherproof thermograph may be used, but the bimetal must be freely exposed. Some workers may prefer models which record at a distance, so that the bulb may be placed in a tree, while the recording mechanism remains accessible. It should be emphasized that large discrepancies will occur during preliminary comparisons between foliage and thermograph if conditions of exposure are not uniform. A surprisingly small amount of shade, which may not be obvious during casual inspection, will produce differences of 2–3°. Also, exposure to winds should be uniform during the tests.

There is no reason why paints with different absorption bands should not be tested. Moreover, in tests related to broad-leaved plants, it might be advisable to wrap a portion of the bimetal in a moist wick to simulate the effects of transpiration. Actually, the leaves of certain field crops appear to be long enough, so that living leaves might be wrapped around a suitably placed bimetal. Other modifications of existing equipment will occur to the reader interested in obtaining more representative temperature measurements.

STATE SUPPORT IN SWEDEN FOR SCIENTIFIC PUBLICATIONS

By Dr. GÖSTA W. FUNKE
Secretary, Swedish Natural Science Research Council

FOR several years science in all civilized countries has enjoyed considerable Government interest—an interest which has, among other things, found expression in the placing at its disposal of considerable sums of money for apparatus, buildings, salaries, etc. On the other hand, very little seems as yet to have been done to facilitate the publication of the ever-increasing flow of the results of the research which has ensued as a consequence of improved conditions for scientific investigation. It is self-evident that facilities for publication must be expanded to keep pace with the expansion in scientific activity if the latter is to be fully utilized. That this fact is appreciated may be seen from the Royal Society Scientific Information Conference held last summer in London. At this Conference several speakers emphasized the necessity for Government measures to support publication, so as to complete the official steps which had already been taken for the benefit of science. Since Sweden has, by decision of the 1947 Riksdag, voted a grant for the publication of the results of scientific work, which is large in relation to the country's circumstances, a short summary of this measure may be of interest and provide a stimulus towards similar measures in other countries where there are corresponding requirements.

The grant in question is only intended for the publication of the results of basic research in the field of pure science; but it is hoped shortly to obtain a similar grant for technical and medical research, etc. The grant amounts to 300,000 Swedish crowns (rather more than £20,000) per annum, and is administered by the Swedish Natural Science Research Council. For purposes of comparison, it may be stated that the Council has at its disposal for distribution in grants for actual research work the sum of 1,000,000 Swedish crowns (about £65,000) per annum. The proportion between grants for research and publication is thus approximately in the ratio of three to one, which shows the importance attached to the facilities for publishing the results produced by research.

For the administration of the grant the Council has set up a special Publications Committee, with representatives of scientific research workers, editors of periodicals, libraries, and printing specialists. The greater part of the grant is used to assist periodicals; but contributions are also made towards text-books and manuals, monographs, etc. A special item is the contribution towards the printing of doctorate theses, of which the expense had formerly, to a large extent, to be borne by the writers of the theses themselves.

It has been possible to start several new periodicals with the help of this grant, as, for example, *Acta chemica scandinavica*, *Tellus* (a geophysical periodical), *Physiologia plantarum*, *Oikos* (a periodical devoted to ecology), and to expand those already in existence. It is the intention of the Council to support only periodicals of international standing. The new periodicals have therefore generally come into existence with the collaboration of, and financial contributions from, the other Scandinavian countries, Denmark, Finland and Norway. In order to promote their circulation abroad, it is stipulated that articles in those periodicals assisted by the Council shall for the most part be written in English, French or German. The Government grant also enables the Research Council to consider other forms of publication.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Tuesday, April 19

Society of Chemical Industry, Agriculture Group (in the Chemistry Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Mr. S. J. Watson: "The Chemistry of Ensilage".

Tuesday, April 19—Saturday, April 23

South-Eastern Union of Scientific Societies (at the King's School, Canterbury).—Fifty-third Annual Congress.

Wednesday, April 20

At 8.30 p.m.—Mr. F. H. Edmunds: "Geological Surveys and their Influence" (Presidential Address).

Friday, April 22

At 7.45 p.m. (at the Chapter House).—Young Naturalists' Evening.

Wednesday, April 20

Royal Institute of Chemistry, London and S.E. Counties Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 3 p.m.—Symposium on "Standardisation in the Chemical Field".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Dr. G. E. R. Deacon, F.R.S.: "Waves and Swell" (Symons Memorial Lecture).*

Royal Microscopical Society (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Prof. J. Gough and Mr. J. E. Wentworth: "The Use of Thin Sections of Entire Organs in Morbid Anatomical Studies"; Mr. E. W. Taylor: "The Phase-Contrast Microscope with particular reference to Vertical Incident Illumination".

Wednesday, April 20—Thursday, April 21

Society for General Microbiology (at the Royal Institution, Albemarle Street, London, W.1).

Wednesday, April 20

At 11 a.m.—Symposium on "The Nature of the Bacterial Surface".

Thursday, April 21

At 10 a.m.—Scientific Papers and Demonstrations.

Thursday, April 21

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Messrs. H. R. Potts and E. G. Lawford: "Recovery of Sulphur from Smelter Gases by the Orkla Process at Rio Tinto".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. N. F. Mott, F.R.S.: "Semi-Conductors and Rectifiers" (Fortieth Kelvin Lecture). (To be repeated on Monday, May 2, at the James Watt Memorial Institute, Great Charles Street, Birmingham, at 6 p.m.)

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. E. W. R. Steacie: "Gas Phase Reactions of Organic Radicals".* (Further Lectures on April 22 and 25.)

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. George Polya (Stanford University): "The Variation of a Circle".* (Further Lecture on Friday, April 22.)

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Discussion on "Frequency Modulation and Amplitude Modulation" (to be opened by Mr. C. E. G. Bailey and Mr. J. R. Brinkley).

Royal Aeronautical Society (at the Municipal College, Portsmouth), at 7 p.m.—Mr. R. R. Duddy: "High Lift Devices and their Use".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Scientific Study of Paintings" (to be opened by Mr. F. I. G. Rawlins, Dr. H. J. Plenderleith and Mr. S. Rees-Jones).

Friday, April 22

Institution of Chemical Engineers (at the May Fair Hotel, Berkeley Street, London, W.1), at 11 a.m.—Twenty-seventh Annual Corporate Meeting; at 12 noon.—Mr. H. W. Cremer: "Scientific Communication" (Presidential Address).

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion.

Physical Society (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Presentation of the 25th Duddell Medal, Prize and Certificate to Prof. K. M. G. Siegbahn; Prof. Siegbahn: 25th Duddell Lecture.

Physical Society, Acoustics Group (at the National Hospital, Queen Square, London, W.C.1), at 5.30 p.m.—Messrs. T. Gold and R. J. Pumphrey: "The Theory of Hearing".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Dr. E. G. Bailey (New York): "Invention and the Sifting Out of Engineering Facts" (James Clayton Lecture).

Institute of Metals, Birmingham Local Section (joint meeting with the Local Section of the Royal Institute of Chemistry, at the James Watt Memorial Institute, Great Charles Street, Birmingham), at 6.30 p.m.—Dr. W. H. J. Vernon: "Corrosion".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Dr. J. D. Kendall: "The Chemistry of Photographic Sensitizing Dyestuffs".

Society of Glass Technology, North-West Section (at the Gas Showrooms, Radiant House, St. Helens), at 7.15 p.m.—Mr. R. J. Callow: "Opal Glasses".

Friday, April 22—Sunday, April 24

Prehistoric Society (at, and in conjunction with, the University of London Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1).—Conference on "Prehistoric Houses and Farms, and some Later Comparisons".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Assistant in Mathematics at the Municipal Technical College and School of Art—The Director of Education, Education Offices, Library Street, Blackburn (April 23).

Public Analyst and Agricultural Analyst—The Town Clerk, Town Hall, Manchester 2, endorsed 'Public Analyst' (April 23).

Lecturer in charge of the Mining Department at Canterbury Technical College—The Acting Chief Education Officer for Canterbury, 78 London Road, Canterbury (April 23).

Senior Lecturer in the Textile Department, a Lecturer in Biology (to teach two of the following: Zoology and Physiology to degree standard, and Bacteriology to intermediate standard), a Lecturer in Physical Chemistry (to teach up to degree standard), and a Lecturer in Physics (to teach Heat and Properties of Matter to degree standard)—The Acting Clerk to the Governors, Nottingham and District Technical College, Nottingham (April 23).

Director of the Chemical Research Laboratory at Teddington—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2490 (April 29).

Assistant Lecturer in Chemistry, a Lecturer in Pure Mathematics, an Assistant Lecturer in Physics, and Lecturers in Education, with special qualifications in (*a*) Principles of Education with Classics, (*b*) Chemistry and Physics, (*c*) Geography—The Registrar, University College, Hull (April 30).

Physicists, Mechanical or Electrical Engineers (Senior Experimental Officer grade) at the Royal Aircraft Establishment, Farnborough, and other establishments in South England—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.437/48A (April 30).

Lecturer in Physics at the Leeds College of Technology—The Director of Education, Education Department, Calverley Street, Leeds 1 (April 30).

Lecturer in Physics and Mathematics—The Registrar, Merchant Venturers' Technical College, Bristol (April 30).

Research Studentships in Experimental or Theoretical Physics—The Director, Wills Physical Laboratory, The University, Bristol (May 1).

Lecturer (Grade II) in Applied Mathematics—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 6).

Lecturer in Mechanical Engineering—The Registrar, The University, Leeds 2 (May 7).

Lecturer in Geography—The Secretary, The University, Aberdeen (May 14).

Principal Scientific Officers at a Ministry of Supply Research and Development Establishment near London: (*a*) Mechanical or Chemical Engineer (Ref. F.223/49A) for work on the design and development of rockets and associated problems; (*b*) Mechanical or Electrical Engineer (Ref. C.208/49A) for work on artillery equipments and associated engineering problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (May 14).

Lecturers or Assistant Lecturers (3) in the Department of Physics—The Registrar, The University, Manchester 13 (May 14).

Assistant Lecturer in Bacteriology—The Registrar, The University, Manchester 13 (May 21).

Research Fellowship in Mathematical Physics, and an Assistant Lecturer (Grade III) in Mathematical Physics—The Secretary, The University, Birmingham 3 (May 30).

Johnstone and Florence Stoney Studentship for research in biological, geological, meteorological or radiological science in Australia, South Africa or New Zealand, and a Junior British Scholarship for research or training for research—Research Applications, British Federation of University Women, Ltd., 17a King's Road, London, S.W.3 (May 30).

Lecturer or Assistant Lecturer in Geology—The Secretary, The University, Aberdeen (May 31).

Boots Research Scholarship tenable at the Long Ashton Agricultural and Horticultural Research Station—The Secretary and Registrar, The University, Bristol (May 31).

Lecturers and Senior Lecturers in Physics—The Secretary of the University Court, The University, Glasgow, W.2 (May 31).

Royal Society, Armourer and Brasiers' Company Research Fellowship in Metallurgy—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (June 1).

Assistant Lecturer in Zoology—The Registrar, The University, Manchester 13 (June 18).

Research Studentships in Science—The Registrar, The University, Manchester 13 (July 1).

Lecturer in Chemistry—The Warden and Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London, W.C.1.

Postgraduate Studentships (3) for Fisheries Research in the Colonial Empire—The Under Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1.

University Graduates (with first- or second-class honours in Botany) for bracken investigations—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen.

Science Graduate as Scientific Assistant on the wood utilization side of the Bureau's scientific information service at Princes Risborough—The Director, Commonwealth Forestry Bureau, New Bodleian Building, Oxford.

Examinership in Botany for Intermediate Examinations in the calendar year beginning January 1, 1950—The External Registrar, University of London, Senate House, London, W.C.1.

Tea Research Officer in Nyasaland to take charge of the existing Tea Experimental Station and also of the projected Tea Research Station—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in Rubber Technology (knowledge of Plastics Technology essential)—The Clerk, National College of Rubber Technology, Northern Polytechnic, Holloway Road, London, N.7.

Honours Graduate (with a first-class basic training in Chemistry or Biochemistry, or Chemical Engineering or Agricultural Chemistry) for training as a Fish Processing Expert—The Under Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Engineers and Physicists in the Engineering Research Department, based at Kingswood, Surrey—The Engineering Establishment Officer, B.B.C., Broadcasting House, London, W.1.

Head of the Department of Physiology—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3.

Lecturer (Grade III) in the Department of Zoology—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4.

SCIENTIFIC MAN-POWER IN GREAT BRITAIN

THE recent debates on defence and on man-power in the House of Commons have one feature in common. Through the more responsible speeches there ran a thread of anxiety as to the man-power resources of Great Britain; whether that distribution was, in fact, the most appropriate for current and future needs, and whether the most effective use was being made of man-power in the occupations where it is at present deployed. In the defence debate, concern as to the actual targets for man-power was expressed on the Government side of the House, notably in regard to recruiting both for the Army and for the Air Force. Further, the Minister of Defence referred to his intention of expanding the research staffs in the scientific services, which for the last two or three years have been kept below the desired strength because of what were regarded as the more urgent claims of the universities, the teaching profession and industry, in accordance with the priorities recommended in the Barlow Report on scientific man-power.

In the man-power debate, however, the note of anxiety was more apparent on the Opposition side. Sir David Maxwell Fyfe pointed out that the Economic Survey for 1949 suggests that the Government no longer considers a better distribution of man-power to be an urgent necessity. While the personnel of the public services has continued to increase, the higher man-power targets for the basic industries of coal, agriculture and textiles have not been achieved. The Minister of Labour, Mr. Isaacs, claimed in his reply that in the greater part of the field the estimated distribution of man-power has been achieved, and he did not appear to be seriously worried by the admitted failure to attain the targets for the basic industries. He claimed that there is little to be done by way of distribution of man-power, and that the objective must now be increased productivity or higher output.

The importance of that objective cannot be overstressed; but there is far too large a proportion of the nation's man-power and woman-power engaged in what are essentially non-productive occupations for the question of distribution to be dismissed so lightly, quite apart from the repercussions of one section of the field on another. One undercurrent in the defence debate was a marked anxiety as to whether under the National Service Acts we are getting the right type of Army and Air Force; and, though the question was not asked, it was clearly in the minds of members that, despite the inherent justice of national service when fairly applied, it is scarcely compatible with a highly efficient long-service regular or professional army, or even with a territorial army.

The reality of the disruption and disturbance caused by national service cannot be denied. Whatever advantages a period of national service may have for many, for some it has real disadvantages: they become unsettled and are slow to adjust themselves to a civilian life and efficient production. This may in part be a by-product of life in the Services under conditions of peace-time, and may possibly be mitigated as we succeed in eliminating waste in the Services themselves and utilizing civil personnel more effectively for non-combatant duties. On the other hand, it may be inherent in the system, and the consequent inefficiency and waste a part of the price to be paid.

The interruption of university training is another matter, and even if the vast majority of students do their national service before entering the university, some waste of talent is unavoidable. At the present time this is a serious matter for those firms who wish to expand their research and other scientific staff to seize what may be fleeting opportunities so far as export trade is concerned. It was announced last month by the Ministry of Labour and National Service that there will be no allocation to industry of science and engineering students completing their normal courses at universities and technical colleges in 1949. The only students allowed to defer their military service, apart from a small number taking up special posts in agriculture or coal mining, will be those who are allowed to continue at the universities in postgraduate research, for example, and a small number allocated to priority posts in the Scientific Civil Service. The former of these will in any event be required to carry out their military service before they attain the age of twenty-six. Once the principle of national service is adopted, it is clear that on grounds of equity there should be no exceptions; nevertheless, the policy thus announced is *prima facie* reasonable. Certainly, on economic grounds it is undesirable to employ a professionally trained scientific man or engineer in any capacity other than that for which he is professionally qualified, even in the Services; this is in itself a further argument for the completion of military service before admission to the universities. Nevertheless, the application of the policy will be viewed with dismay by firms which are already experiencing acute difficulty in recruiting scientific staff and which do not share the optimism of the Ministry of Labour as to the numbers available of trained scientific workers and technologists.

It is not only industry that is affected. At the annual meeting of the Carnegie Trust for the Universities of Scotland in Edinburgh on February 21, the complaint was made that Government departments, as well as industrial concerns, were outbidding the universities for their staffs, and that in open competition for brains, scholarship and particularly character, the Scottish universities were severely handicapped by lack of means.

This position has not, of course, escaped the notice of the University Grants Committee, and in the House of Commons on March 15 the Chancellor of the Exchequer said that he accepted the view of the University Grants Committee that the increase of salaries which had become necessary in the medical faculties carried with it, as a necessary consequence, a revision of salaries in the other faculties. The provision made for the universities in the Civil Estimates for 1949–50 will allow supplementary grants to be made to adjust such salaries as from October 1, 1949, on the basis of £1,600 for professors (in London, £1,650), up to £1,600 for readers and senior lecturers, £500–1,100 for lecturers and £400–500 for assistant lecturers. This announcement indicates that steps will be taken to rectify a situation which has been regarded with increasing concern by one body after another that has looked at university finance in recent years.

Nevertheless, that is not the most important aspect of the situation. The central fact to be realized is that a satisfactory distribution of scientific and of general man-power and a correct overall policy may be distorted by action taken to rectify an admitted weakness, or even grievance, in one particular field, because of its repercussions in other sectors. Quite recently, reference was made in these columns (see *Nature*, December 25, 1948, p. 977) to the new tensions which the recommendations of the Spens Report threatened to introduce, particularly when the operation of the economic factors which would normally restore the balance was retarded. Further point is given to those comments by the announcement on March 17 of the salaries and conditions of service for specialists in the new health service which, based on the recommendations of the Spens Committee, the Government proposes to adopt. We are here only concerned with the fact that the standard set for specialists is bound to influence the earnings of other medical men and, through them, the earnings of other professions. The importance of the financial motive can be over-estimated; but it is sometimes a decisive factor in the choice of profession and, perhaps more important still, in the choice of occupation within a profession. To use it without much forethought and careful preparation to adjust the distribution of man-power within a profession is a delicate operation and liable to be attended with awkward and undesirable effects elsewhere.

Although it is a tool to be used only as a last resource, the economic motive is one that cannot be ignored. Hitherto, the professional classes generally have exercised considerable restraint in the matter of remuneration during an inflationary period. The Parliamentary and Scientific Committee has therefore done well to appoint a broadly based subcommittee to inquire into the whole subject of payment of scientific and medical teaching staff at the universities, and the general effects on those of similar standing in other spheres. In that unenviable task, they may well find some whose training is far more exacting and starts at a much higher intellectual level than that of the medical graduate but whose financial rewards are far lower; they may well also uncover unfounded claims to higher personal incomes. A report from so representative a committee may be invaluable in restoring some balance and sense of justice.

Economic factors are, however, only one disturbing element; but they well illustrate the way in which Government action itself may have repercussions which affect the distribution of man-power and the balance it desires. More, they remind us that the distribution of man-power is a dynamic and ever-changing element in the nation's affairs. It is rarely static, being affected by internal changing circumstances such as technological developments, and also by external events. Man-power policy can never be finally determined. It must be reviewed continually in the light of the needs of the day, and with the fullest possible informed public discussion, if the Government is to be sure of the public support without which no man-power policy can succeed.

Vital as it is to secure maximum productivity, neither industry nor the nation can afford to accept the view that the distribution of its workers does not require continuous, rigorous and impartial scrutiny. Before embarking on a policy of continued expansion of the Government services, the Minister of Labour should satisfy himself—and also industry and the universities—that there are weighty reasons for it. In view of the general restriction of research activities outside the Government service, due to the present shortage of scientific man-power in Great Britain, the case for increased staffs in Government establishments and the Service departments requires careful consideration.

CHEMISTRY OF THE CAROTENOIDS

Carotinoide

Von Paul Karrer und Ernst Jucker. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften, 17: Chemische Reihe, Band 3.) Pp. 338. (Basel: Verlag Birkhäuser, 1948.) 43 Swiss francs.

POSSIBLY no better example can be found of astonishingly rapid development of the chemistry of a widely distributed and exceedingly complex group of natural compounds, following upon the introduction of micromethods and specially devised processes, than is afforded by the carotenoids. The first monograph devoted to this topic, "Carotenoids and Related Pigments" (by L. S. Palmer; New York, 1922), contained virtually no detail of structural significance, though this was soon to appear (see, for example, "Carotenoide", by F. Meyer in Meyer–Jacobsen's "Lehrbuch der organischen Chemie", first and second editions, vol. 2, chapter 5; 1929). The adoption of micromethods of oxidation and reduction, the recognition of light absorption of the carotenoids as a valuable characteristic, and, above all, the timely revival of chromatographic analysis, without which the development of carotenoid chemistry might well have been delayed for years, resulted in a surprisingly swift revelation of the main outlines of the chemistry of natural polyenes.

For fifteen years L. Zechmeister's "Die Carotinoide" (Berlin, 1934) has been the sole text dealing exclusively with this detailed carotenoid chemistry. These years, despite the attention of chemists in many countries having been directed elsewhere, have seen much in this field beyond the normal addition to what was known of structural detail. This growth has certainly been notable, for there are now some seventy known naturally occurring carotenoids, the structure of about 50 per cent of which is now fairly precisely elucidated, together with a very large number of stereoisomerides and polyene degradation products. The carotenoids are no longer, however, of interest solely to the academic chemist concerned with the structural patterns of natural molecules. Connexions with vitamin A, visual purple, phototaxis, and even fertilization in micro-organisms, among other topics, afford them outstanding biochemical interest, and it may be said at once that in the volume under review this old and new material has been surveyed and mostly reproduced in all essential detail in masterly fashion.

All that the chemist can reasonably expect in respect of historical data, occurrence, preparative detail, physical and chemical characteristics, derivatives, and original references to individual pigments is set out with exemplary clarity and, it seems, accuracy, in the special section of this book. Readers will be specially grateful to the authors for having withstood the temptation to abbreviate the necessarily cumbersome structural formulæ, as well as their lavish use of tables and the inclusion of representative spectral curves and coloured plates of carotenoid crystals.

General occurrence, determination of structures, physiological significance, and, among other features, distribution of the carotenoids are summarized with scholarly precision, often in tabular form, in a general part; all information such as the organisms producing specific pigments and the pigments produced by specific organisms is made almost instantly accessible, and few facts only (for example, work on vitamin A) seem to have escaped inclusion, obviously because of their recent discovery.

This is in every way a finely produced and very timely work which, so far as can be foreseen, will be the standard text and largely meet the needs of workers in the field of carotenoids for some considerable time ahead.

A. H. Cook

GEOLOGY AND GLACIOLOGY OF THE PLEISTOCENE PERIOD

Glacial Geology and the Pleistocene Epoch

By Prof. Richard Foster Flint. Pp. xviii+589+6 plates. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 36s. net.

PROF. R. F. FLINT'S distinguished work in the broad field of glacial geology has been prominent for a generation, and his book is important for that and for other reasons. It deals with the Pleistocene period from the points of view of a geologist and of a glaciologist. Characteristically, perhaps, the author has used stream-terrace data as little as possible, and indeed much of the field work in North America lends itself to the successful pursuit of other methods. Correlation, perennially a difficult subject, is treated so far as possible on geological evidence, not on archæology. The author strives to avoid deduction from any theory of climatic fluctuation which sets up a fixed chronology; he incorporates with his own wide knowledge and experience a considered opinion of an enormous amount of literature, of which a formidable list occupies some forty pages. Significant is the author's introductory statement that "a continuous effort has been made to discriminate between reasoning by induction from field evidence and reasoning by deduction from assumed general conditions"; and there, in a sentence, lies the duty of every scientific worker in the field, laboratory and library.

The book is dedicated to Max Demorest, who lost his life while going to the aid of others in Greenland during the War, and his important contributions to glaciology are incorporated in the author's essential thesis on ice movement. Ten of the twenty-three chapters are given to an objective study, well documented, of glacier ice, its motion and regime, form and distribution, powers of erosion and deposition, periglacial deposits, and glacial stratigraphy. For many, these careful and up-to-date essays will be the *raison d'être* of the book. But sober and engrossing chapters follow on the glacial stratigraphy of North America, Europe and other lands, on changes of level of sea and land, on Pleistocene chronology and climates, on the causes of climatic fluctuation, and the fossil record. Specialists, each in his own field, will be able to supply references and data which will post-date some of those given in the book; some of the subjects are notoriously controversial, but, in the reviewer's opinion, Prof. Flint has dealt faithfully with the past and kept a keen eye to the future of many and varied researches.

The text is well illustrated, with a large number of photographs, some of them excellent, new and intriguing text-figures, tables of correlation and of estimated volumetric data on glaciers, both past and present. Folding plates at the end of the book show the present distribution of land ice, pack ice and storm tracks in southern and northern hemispheres; and stimulating impressions of the same features in the latter hemisphere during the last (Wisconsin) Glacial Age; distribution of loess (in particular) in Europe; glaciated areas in the western United States (with form-lines based on the general altitudes of the floors of the lower cirques); and a sketch-map of the glaciations of Europe. Author and publisher are to be congratulated on the general appearance and presentation of text and illustrative material.

"Glacial Geology and the Pleistocene Epoch" must surely become a standard work of reference; but it is more than that because it is a balanced, objective, creative, and stimulating book, written for an educated public rather than for a few specialists.

K. S. SANDFORD

APPLICATIONS OF GROUP THEORY TO SOME PHYSICAL PROBLEMS

Theory of Groups and its Application to Physical Problems

By S. Bhagavantam and T. Venkatarayudu. Pp. xi+234. (Waltair: Andhra University, 1948.) 20 rupees.

IT is an obvious truism to say that the day is long past when each 'branch' of science was placed in a separate water-tight compartment on its own, divorced from all the other 'branches'. On the contrary, it has become increasingly clear in recent years that these 'branches' are unified in one collective science, and that an advance in one 'branch' will often lead, at a later date, to an advance in some apparently totally different field of investigation.

This is particularly true when the former field is pure mathematics. Thus, the early work on infinite matrices, and the famous book of Courant and Hilbert, "Methoden der Mathematischen Physik", 2 vols. (Berlin: Springer, 1924 and 1937), provided just what was wanted for the development of the Heisenberg–Dirac theory of quantum-mechanics; then linear operators in Hilbert space paved the way for a mathematically sound discussion of Schrödinger's wave equation, and led to proofs, by von Neumann and others, of the spectral resolution theorem for unbounded self-adjoint (hypermaximal) operators. Again, in 1913, by use of the Baire–Osgood theorem that the continuum is not a set of the first category, Plancherel and Rosenthal gave independent proofs of the impossibility of the Maxwell–Boltzmann theory of gases.

Now, in the book under review, the authors provide a lucidly written and well-designed exposition of the application of another abstract branch of pure mathematics, namely, group theory, to some physical problems. The book is exactly what the authors claim it to be, namely, a self-contained and connected account of the above application, intended for those who have no ready access to orthodox treatises already written on the subject. As such, it does not contain novel results, but shows the application of a mathematical tool to existing knowledge. A commendable feature of the book, which is of a mathematical nature, is that physical arguments are not glossed over, and all the results are discussed in detail.

After some introductory chapters on groups and lattices in one and two dimensions, applications of group theory are given to vibrations of a dynamical system, vibrational Raman effect and infra-red absorption, some simple molecules, lattices in three dimensions, vibrations of a crystal lattice, Raman scattering in crystals, rotation groups, problems of atomic spectra, electron spin, some aspects of band spectra, etc. There are also useful appendixes on various matters arising from the text.

In a foreword, Sir C. V. Raman writes of the book: ". . . It represents a serious effort to present a branch of mathematics which is of great and growing importance to physicists generally in a manner which will appeal to and interest them. I believe that the book will be widely read and appreciated." The present reviewer entirely endorses this opinion, and hopes that the book will be read, not only by physicists and applied mathematicians, but also by pure mathematicians who are not too 'pure'.

R. G. COOKE

WOODY PLANTS FOR AUSTRALIAN GARDENS

Shrubs and Trees for Australian Gardens

By Ernest E. Lord. Pp. xxiii+453+125 plates. (Melbourne and Sydney: Lothian Publishing Co., Pty., Ltd., 1948.) £5 5*s*. 0*d*.

THE flora of Australia is one that has always attracted the horticulturist as well as the botanist, both on account of the beauty of many of its species and also because of the high proportion of endemic types. The present work, which is written in non-technical language by a landscape architect and former curator of parks, treats of the trees and shrubs grown in Australia with respect to their horticultural value. To this end the descriptive matter is not such as to serve for the identification of species, but rather for assessing their garden significance and appropriateness for diverse purposes. Sections treat of the trees and shrubs recommended for the various climatic zones in Australia and for special requirements such as for town and roadside planting, those suitable for arid conditions, for the seaside and for small gardens.

The admirable illustrations portray some hundred and fifty species, and of these fifteen are represented in colour. It is scarcely surprising to find that the characteristic Australian family of the Proteaceæ occupies a prominent place among those of especial garden merit. The beautiful crimson *Telopea truncata*, a tree from Tasmania that attains a height of 20–30 ft., is portrayed in its natural colour, but the West Australian *Banksia prionotes* and *Banksia coccinea*, the former a yellow-flowered tree and the latter a crimson-flowered shrub, have a beauty of form to which the black-and-white photographs do full justice. Other noteworthy illustrations from the same family are *Dryandra formosa*, *Hakea laurina*, *Isopogon anemonifolia* and *Stenocarpus sinuatus*. Of the endemic Epacridaceæ, the figure of *Sprengelia incarnata* is especially effective, while the Rutaceæ are illustrated by the charming Correas and Boroneas, which emphasize the relationship of this family with the Ericaceæ. From the Myrtaceæ come the eucalyptuses, the true bottlebrushes (*Callistemon*), and their close relative *Calothamnus*, while mention must be made of the magnificent specimen of *Helichrysum thyrsoideum* and of the interesting blue-flowered Boraginaceous shrub, *Halgania cyanea*.

It is unfortunate that, in endeavouring to compass the trees and shrubs of a continent within the compass of a single volume, so little space could be devoted to each and so little data furnished as to soil conditions. Moreover, despite the desirability of avoiding technicalities in a volume of this character, the absence of any indication as to affinities is to be regretted, since the family to which an unfamiliar subject belongs is often a valuable indication to an experienced gardener as to treatment.

E. J. SALISBURY

CONDUCTION OF ELECTRICITY IN METALS

Leitfähigkeit und Leitungsmechanismus fester Stoffe
Von Prof. Eduard Justi. Pp. xii+348. (Göttingen: Vandenhoek und Ruprecht, 1948.) 15 DM.

THIS book originates from a lecture course which the author, himself an experimental physicist, gave during the War to an audience consisting largely of electrical engineers, with the aim of bridging the gap between the outlook of engineers and physicists. The book covers a field somewhat wider than the original lectures and is written partly in collaboration with experts on special subjects.

The specialization of science has been widely commented upon, and its dangers for the future of science and human thought in general are recognized. Since this book is published with the purpose of counteracting some of the detrimental effects of specialization and establishing stimulating contacts between the worlds of science and industry, it should be welcomed.

Conduction in metals is a phenomenon on which the routine work of electrical engineers is founded, and the author conveys the views of modern physics on the subject to a public to whom presumably even the older physics is not too familiar. This is done by discussing conductivity in terms of moving electrons and reviewing all other phenomena through which the dynamics of electrons in crystals is accessible to observation, such as the Hall effect, thermo-electricity, superconductivity, rectification in surface layers, semiconductors, photoconductivity, ionic conductivity of crystals and similar subjects.

The book is written as a review rather than as a treatise. It consists of accounts on the experimental work in various fields. The author lets the experimental facts speak for themselves and refrains from stressing opinions of his own. Theories are not presented in full, but theoretical results are freely quoted when this is necessary in discussing experiments. There is, however, an elementary introduction to the wave mechanics of electrons in metals.

An apparatus is described by means of which the interference of electrons was demonstrated in the lecture theatre in such a way as to impress the wave nature of matter on the largely non-academic audience. The author is anxious to point out the possible practical applications of phenomena that are, so far, of academic interest only, and he reports, therefore, in detail on the experimental work on the utilization of the free energy of fuel in galvanic cells.

The ample lists of references are obviously supposed to cover everything of importance, including recent work. Heisenberg's papers on superconductivity are quoted; but there is no reference to the recent electron theory of electric breakdown[1].

The book will be useful, in the first instance, to those readers who are interested in the facts rather than in their interpretation. It provides plenty of information for the non-expert, academic or industrial, and may be appreciated even by experts for reference purposes.

R. EISENSCHITZ

---

FOOD CROPS

Brassica Crops and Allied Cruciferous Crops
By Chas. H. Oldham. (Agricultural and Horticultural Series.) Pp. 296+20 plates. (London: Crosby Lockwood and Son, Ltd., 1948.) 21*s*. net.

Grain Crops
By Harold K. Wilson. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. xi+384. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 24*s*.

THE production of food continues to be of vital importance to mankind, and there is no dearth of books for the guidance of cultivators. In the two books under review there is a wealth of information on the growing of bigger and better crops.

In "Brassica Crops and Allied Cruciferous Crops" the author has collected together from various, and often inaccessible, sources accurate information about modern methods of growing and marketing vegetables, and has incorporated the results of his own wide experience and observations. He has also given useful descriptions of the varieties generally grown. All this is arranged in thirteen chapters, one chapter for each vegetable, and each chapter is of precisely the same pattern, comprising sections on botanical and historical features, the principal types and varieties, geographical areas of production, maintenance of pure stocks and production of seed, cultivations, marketing, diseases and pests. The alphabetical arrangement of the chapters is confusing, as it involves, for example, the separation of the savoy from the cabbage by no less than six chapters, although both vegetables have many features in common. A more natural sequence would have been obtained by discussing the vegetables of the *Brassica* genus in consecutive chapters.

The book is well illustrated by drawings and photographs, and there is an excellent index. The botanical information is not always accurate, one obvious inaccuracy appearing in Fig. 1, in which the siliqua of the wild cabbage is depicted dehiscing from the apex towards the base. Such details, however, do not detract from the value of the book to the practical man, and commercial growers and private gardeners alike will find this volume invaluable.

"Grain Crops" is an expansion of outlines of a course of lectures on the various phases of the production of grain crops, given to students in the College of Agriculture, University of Minnesota. The subject-matter is arranged in twenty-three chapters, of which the first eight are concerned with a very brief review of the fundamentals of botany, plant classification, the world distribution of grain crops, and a general discussion of their culture. This section is followed by a more detailed discussion of individual grain crops, and these include not only the members of the grass family but also such crops as flax, buckwheat and soybeans. The book concludes with a chapter on the improvement of grain crops.

Each chapter is followed by a list of review questions and a bibliography; but one seeks in vain for a reference to any literature other than American. With the exception of the mention in a footnote of "The Wheat Plant" by John Percival, all literature published outside the United States is ignored. The whole subject is treated purely from the American point of view, since crop rotation, methods of culture, lists of varieties, storage and uses of the various crops all refer solely to American conditions.

While this book is undoubtedly very useful for the American agricultural student and the American farmer, it is of very limited value to agricultural students in Great Britain or, indeed, in many countries outside the United States. The omission of references to work on grain crops by men of science in other countries emphasizes this statement, and surely the "more advanced students", mentioned by the author in his preface, would profit enormously if the "liberal use of selected references" was more truly liberal and indeed international. A. G. ERITH

CRYSTAL STRUCTURES OF INORGANIC COMPOUNDS

Crystal Structures

By Ralph W. G. Wyckoff. Section 1. Pp. viii + 442. (New York and London: Interscience Publishers, Inc., 1948.) 48*s*.

IN 1931 Dr. R. W. G. Wyckoff's "Structure of Crystals" was published and was followed by a supplement in the year 1934; these volumes contained the results of crystal-structure determinations up to about 1933, and many X-ray crystallographers will have found them of utmost value, both as sources of information about structures and as sources of references.

The present work will therefore be greeted by many as an old friend, and they will not be disappointed in its contents. The sections on crystal-structure determination have disappeared, while the discussions of structures and the relationships between them have been extended in the light of recent theories. The details of the structures are repeated from the earlier volumes, together with the well-known diagrams, but the references begin at the year 1933, where the first supplement finished.

There are, however, many changes. The book is published in loose-leaf form, and is printed in imitation typescript; only about half of the book is yet produced, and the rest is to be published in two sections. The author has adopted this method of procedure in order that the main part of the book could be published within a reasonable time; corrections may be made later by the substitution of pages, and new material can be added in appropriate places. The part so far produced is on inorganic structures, arranged in order of complexity of chemical formulæ—elements, compounds *AB*, compounds AB_2, etc.—and the two further sections promised are to cover the inorganic compounds that remain and organic compounds.

One cannot but agree that this method of publication has its advantages for this sort of work, and one must bear with the disadvantages that are inevitable in loose-leaf publications. The pages tend, of course, to misalignment, although they are well clamped together by a simple device. Some instruction on the method of release of the covers would be valuable; X-ray crystallographers may be used to trial-and-error methods; but they do not wish to try them on their books.

The text is, on the whole, well written, although there are some phrases that ring strangely to the British ear: "non-rare gas shell atoms" is an awkward construction that cannot be improved by any ordinary method of hyphenating, and "fifth-column elements" has not the happiest of connotations. The author has also a tendency to use too few commas, as the following extract shows: "If as was done in Chapter II when discussing cobalt and the two forms of graphite layers in these three positions are designated as 0, 1 and 2, then . . ."; a comma after graphite is definitely required.

A technical difficulty, with which the author has unfortunately made no attempt to cope, is that due to the recent change in unit of measurement. Measurements are all given as in Angstrom units; but they are actually in kX. units. If it was not possible to correct all the dimensions given, a covering note explaining the difficulty should have been given; one hopes that such a note will appear in the further sections. But there is no doubt that difficulties will begin to appear when present structures, quoted in true Angstrom units, are included.

The book will inevitably be compared with the "Strukturbericht". Both works cover the same ground in much the same fashion, and it is in this respect that the author claims that the loose-leaf form of publication should have a decided advantage; it will enable all the data for a given material to be kept together, whereas with the "Strukturbericht" one has to look through all the volumes. It will be interesting to see how the experiment works in practice. Certainly all X-ray crystallographers will wish it well and will be grateful to Dr. Wyckoff for the large amount of time and effort that he has obviously spent in compiling the work. H. LIPSON

Chemical Architecture

Edited by R. E. Burk and Oliver Grummitt. (Frontiers in Chemistry, Vol. 5.) Pp. x+202. (New York and London: Interscience Publishers, Inc., 1948.) 4.50 dollars; 27*s*.

THE Western Reserve University in Cleveland, Ohio, has established a reputation for series of lectures in what is usefully termed the "Frontiers of Chemistry". These lectures deal with a variety of topics of current interest. In an expanded and therefore more acceptable form they have been published at intervals during the past few years. This is the fifth volume of the series. The need for reviews of this kind is perhaps more pressing than in normal times because few chemists have had the opportunity of writing monographs on those branches of chemistry in an active state of development.

Under the all-embracing title of this book many topics are discussed by a number of eminent chemists of the United States. In every case the lecture has been much expanded and fully documented, so that each article is an up-to-date and complete summary of the particular line of investigation. Dr. H. S. Taylor leads off with a generally discursive article on the influence of molecular geometry in reaction mechanism, particular attention being paid to heterogeneous reactions where molecular geometry is often of overriding importance. Dr. C. P. Smyth appropriately discusses the more recent contributions that dipole measurements have brought to the elucidation of the structure of a number of molecules in which the method is of particular value. There is a more than usually complete survey of the structure of co-ordination compounds by Dr. W. C. Fernelius. To go to the other extreme of difficulty, Dr. B. E. Warren deals with the important contribution X-ray diffraction studies have made to measuring the degree of disorder and of short-range order in substances like carbon black and certain alloys; and Dr. M. W. Tamele deals with the difficult problem of the structure of gels used as a substratum for the production of catalysts. The longest article, on "Light Scattering in Polymer Solutions", by Dr. H. Mark, is particularly opportune. There has been much talk and a great deal of experimenting with light scattering but not nearly enough published matter, theoretical or experimental. This article will be especially useful to all those interested in this important method.

H. W. Melville

Pohledy do nebe

Problémy a výsledky moderní astronomie. Napsal Dr. Hubert Slouka. Pp. 460+43 plates. (Praha: Nakladatelství Orbis, 1947.) 165 Kčs. *In Czech.* (Exploring the Skies: problems and results of modern astronomy. By Dr. Hubert Slouka. Prague: Orbis, 1947.)

THIS recent astronomy book by the Czech astronomer, Dr. H. Slouka, aims at introducing a wide public to some of the most interesting astronomical problems of to-day. It is not intended as a text-book but rather to stimulate a more specialized study of its large variety of subjects. It falls into eight main chapters: the road to the stars; telescopes of to-day and to-morrow; the sun; the world of the planets; celestial wanderers; the world of the stars and nebulæ; beyond the Milky Way; and the birth and death of worlds. Tables of astronomical data are added as well as a useful bibliographical list. Many of the illustrations are drawings new to books of this kind; in addition, some forty plates are well chosen and beautifully reproduced. The first two editions of the book were published in Prague in 1942, and the author's remarks bear witness to the difficulties of the time in which he worked at it. The book is very vividly written in a manner which the author hopes will help "to win for astronomy new and enthusiastic friends who will strive for this most attractive of all sciences to penetrate to all sections of the public". A. B.

An Introduction to Mathematics

By Dr. A. N. Whitehead. (Home University Library of Modern Knowledge, No. 18.) Twelfth impression. Pp. v+192. (London: Oxford University Press, 1948). 5*s*. net.

THAT the late Prof. A. N. Whitehead's little volume should establish itself as a classic is not surprising. It was published in the "Home University Library" in 1911, was reprinted about eight times, and finally was reset in its present form in 1948 under the supervision of Prof. J. H. C. Whitehead, of Oxford, the late author's nephew. The diagrams have been re-drawn; but apart from the correction of inaccuracies and typographical errors, the author's original wording has, in no instance, been altered. In the reset edition the number of pages has been reduced from 256 to 191; but the text is still quite clear and readable. In seeking to explain the nature of mathematics, it still affords a very interesting account of how mathematics forms the background of all science.

Asparagus

By Alfred W. Kidner. Pp. 168+17 plates. (London: Faber and Faber, Ltd., 1947.) 15*s*. net.

THAT delectable vegetable, asparagus, has been cultivated by man for more than two thousand years; the elder Cato speaks of its cultivation, and it may be presumed that it was known and grown long before that time. Yet in all this long time it has changed little in its character, and, as the author of this book points out, no really fixed and distinct forms or varieties have been produced. It is strange that so esteemed a luxury should never have received much attention from plant-breeders. Largely through chance, Mr. A. W. Kidner took up the problem of selection and breeding of giant forms of asparagus, and through long years of empirical observation, isolation and cross-fertilization developed strains of superlative quality. There is no doubt of the success that has attended his efforts, and they show what might still be done if the genetics of the plant were really worked out and strains homozygous for the desirable qualities fixed.

The author lays no claim to being a man of science, and throughout the work there runs a curious implication almost of surprise that asparagus should respond to controlled breeding methods—a suggestion of pleading a case that special laws operate in this one instance and that it may be difficult to convince the reader of the value of breeding. In this respect, the book is needlessly repetitive; but, as an otherwise straightforward account of how the practical man can go about developing his own super-quality strains and how to grow and market them, the book is of great value. It should certainly stimulate the new National Vegetable Research Station, when it begins operations, to take up the study of the genetics of asparagus. R. H. Stoughton

SOME RECENT ADVANCES IN RADIOCHEMISTRY*

By Prof. H. J. EMELÉUS, F.R.S.

IN the decade since the discovery of atomic fission by Hahn and Strassmann, the subject of radiochemistry has undergone rapid development. It has always been in the background of all the major advances in radioactivity, and the very magnitude of these advances in recent years has resulted in the presentation to the chemist of a wide range of new problems. Three of these will be discussed briefly here. The first, the chemical separation of the fission products of uranium and other fissile elements, is largely a matter of chemical analysis and differs from more familiar analytical problems only in complexity and in the fact that microchemical techniques are used. The second problem, that of fitting the many new radioactive isotopes of the heavy elements into modifications of the classical decay series, has been solved by a combination of the physical and the chemical methods of approach. The third major problem is the study of the chemistry of the new transuranic elements neptunium, plutonium, americium and curium, as well as of those of atomic numbers 87 (francium), 85 (astatine), 61 (illinium or prometheum) and 43 (masurium or technetium), which probably have not been isolated from natural sources but are now available, in small amounts, in the form of radioactive isotopes formed by suitable nuclear transformations.

Fission Products

The isotopes which are known to undergo fission with slow neutrons are uranium-233, uranium-235 and plutonium-239; others (thorium-232, ionium-230, protoactinium-231, uranium-238 and neptunium-237) require fast neutrons, and less information is available on the fission products†. In the fission of uranium-235 by slow neutrons, to take an example, two lighter nuclei are formed in each fission. The following is a typical equation:

$$U_{92}^{235} + n_0^1 = Kr_{36}^{92} + Ba_{56}^{141} + 3n_0^1 + 175\ \text{Mev.}$$

The nuclei formed fall into two groups, a light and a heavy, the most abundant members of which are in the ranges $Z = 35$ to 43 (bromine to technetium) and $Z = 51$ to 58 (antimony to cerium), other less abundant nuclei falling between and outside these two ranges. The fission products have masses greater than those of the heaviest natural stable isotopes of the elements in question. In the case of the krypton and barium isotopes mentioned above, for example, the heaviest stable isotopes have masses of 86 and 138 respectively, and the fission fragments are β-active, which reduces the mass to charge ratio of the nucleus to a stable value. This gives rise to fission decay chains of which the accompanying are typical.

$$Kr_{36}^{92} \xrightarrow[\beta]{3s.} Rb_{37}^{92} \xrightarrow[\beta]{\text{short}} Sr_{38}^{92} \xrightarrow[\beta]{2\cdot7h.} Y_{39}^{92} \xrightarrow[\beta]{3\cdot5h.} Sr_{40}^{92}\ \text{(stable)};$$

$$Xe_{54}^{141} \xrightarrow[\beta]{3s.} Cs_{55}^{141} \xrightarrow[\beta]{\text{short}} Ba_{56}^{141} \xrightarrow[\beta]{18min.} La_{57}^{141} \xrightarrow[\beta]{3\cdot7h.} Ce_{58}^{141} \xrightarrow[\beta]{28d.} Pr_{59}^{141}\ \text{(stable)}.$$

In such chains it is possible for an intermediate member to be formed directly by fission, but in general the chance of this happening becomes less as the stable end is approached. The mass number in the chain is constant, and determinations of fission yield are generally made with reference to this mass number rather than to any particular element. The fission yield is defined as the percentage of all fissions for a given range of neutron energy yielding nuclei of a particular mass number, and its determination calls for methods of analysing the fission products chemically and also for a correlation between the number of fissions and the amount of each mass formed.

In the chemical analysis of fission products, carriers and so-called hold-back carriers are used. The need for a carrier arises from the exceedingly small absolute weights of radioactive material present in the mixture. In separating a particular element, a small amount (1–10 mgm.) of inactive isotopic material is added, which renders manipulation on the micro scale possible. Inactive hold-back carriers are used in similar amounts to minimize radioactive contamination of the element sought by other fission products, which would otherwise be carried down in precipitation reactions. The hold-back carriers do not eliminate this contamination, but they ensure that when it occurs it involves largely the inactive atoms of the hold-back carriers and not the isotopic fission products.

Material for the chemical separation of fission products is now obtained readily by the irradiation of uranium or one of its compounds in the atomic pile. In the early work on fission other neutron sources, such as a radium–beryllium mixture, were used. The following are typical of the many methods of chemical separation employed, carriers and hold-back carriers being used in most cases.

(1) Separation of barium and strontium as nitrates by precipitation with fuming nitric acid, followed by precipitation of barium as chromate and strontium as sulphate.

(2) Direct removal of the rare gases krypton and xenon, followed by the mass spectrographic determination of the various isotopes.

(3) Precipitation of sulphides of arsenic, germanium, selenium, tellurium, molybdenum, antimony, technetium, rhodium and palladium with hydrogen sulphide in acid solution, followed by further separation of the individual elements.

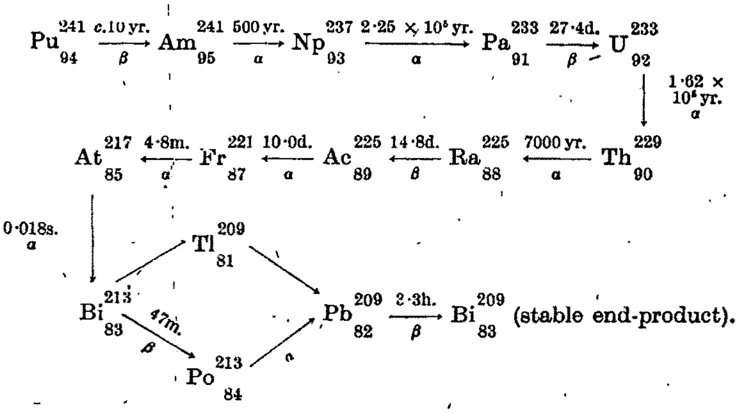
(4) Separation of the rare earths by ion exchange resins.

Following the separation of each element, it is essential to study, and if necessary analyse, the decay characteristics of the product, which may contain several isotopes. Further chemical separation of a daughter element formed in the decay of that isolated is also carried out in many cases, in addition to which the activities observed are identified when possible with those due to isotopes formed in unambiguous nuclear reactions brought about, for example, with the aid of the cyclotron. The information so gained has been fitted together gradually to give a fairly complete picture of all the fission products and their decay chains.

---

* Based on a course of three lectures delivered at the Royal Institution on March 15, 22 and 29.

† The information contained in this article is drawn largely from declassified reports issued by the United States Atomic Energy Commission, the Division of Atomic Energy of the National Research Council and the Division of Atomic Energy of the Ministry of Supply.



In the atomic pile, the amount of each fission product grows to a constant value at which its rate of formation equals its rate of decay. This makes possible the direct comparison of the relative yields of various fission products from observations made on the activity of materials from the chemical separation, provided the observed activities are corrected for decay during the chemical separation, and also for the fact that irradiation in the pile may not have been long enough for the activity to grow to its saturation value. Other corrections for factors inherent in the counting of β-particles of different energies may also be necessary. To transform these relative values to absolute values, it is necessary to determine absolutely the fission yield of some one isotope. The 12·8-day isotope barium-140 has been much used as a standard, because of its convenient life and ease of separation. If Y_R and Y_S are the yields of two fission products R and S, and $\overset{\infty}{D_R}$ and $\overset{\infty}{D_S}$ the respective saturation disintegration-rates, then $Y_R/Y_S = \overset{\infty}{D_R}/\overset{\infty}{D_S}$.

In determining the absolute fission yield of the standard substance, the essential experiment is to mount a very small weighed sample of a uranium compound in a fission-counting chamber in the thermal column of the atomic pile, and to place in the same neutron flux a larger known sample (for example, 0·1 gm.) of the uranium compound for subsequent chemical analysis. A known weight of carrier is used in the analysis, and the actual weight of this carrier recovered is measured. It carries with it a proportionate amount of the total activity of the standard fission product. Fission-yield curves obtained by the procedure outlined have now been published for uranium-233, uranium-235 and plutonium-239, and they show a great similarity, apart from small displacements in mass due to the different masses of the fissile nuclei.

The New Radioactive Decay Series

The second major radiochemical problem, the place of the transuranic elements in the decay series, has had as its most striking result the discovery of a new series, the neptunium or ($4n + 1$) series, the longest lived member of which is the isotope Np^{237}_{93}. There are, in addition, a number of new branches and extensions of the classical series into which isotopes of elements 93, 94, 95 and 96 have been fitted. The decay scheme of the neptunium series, none of the members of which are known to occur in Nature, is shown above.

The study of the greater part of this series, isolated members of which have been known for some time, has followed from the isolation of uranium-233 in moderate amounts from thorium irradiated in the atomic pile, where it undergoes an (n, γ) reaction followed by two successive β-decays. The radium isotope is separated chemically from the uranium-233 solution, using a barium carrier, and is then found to grow an activity due to an actinium isotope, which is separated with a lanthanum fluoride carrier. This established the β-activity of the radium isotope. The actinium isotope shows four α-activities, the energies of which are studied with the pulse analyser. Of these one, due to the alkali metal francium, may be separated chemically with cæsium perchlorate. The isotope bismuth-213 is separated with a bismuth carrier, and the isotope lead-209 is identified, when it has grown in the actinium solution, by using a lead carrier. This particular activity has been produced by several independent nuclear reactions and the isotopic assignment is clear. There is little direct chemical evidence for the isotopes astatine-217, polonium-213 and thallium-209, and in these cases identification depends largely on physical methods.

The above gives only a general indication of the chemical approach to a problem of this type. Other similar series of radioactive isotopes have been produced by the use of the cyclotron, particularly at the University of California, where so many of these new developments have originated. As an example of the production of a series of synthetic isotopes which form a branch to one of the main decay series, work on the protoactinium series may be mentioned. The parent isotope, protoactinium-230, is formed in the deuteron or helium ion bombardment of thorium and decays according to the following scheme, the last member shown, radium C′-214, being a member of the classical uranium–radium series.

$$Pa^{230}_{91} \xrightarrow[\beta]{17d.} U^{230}_{92} \xrightarrow[\alpha]{20\cdot8d.} Th^{226}_{90} \xrightarrow[\alpha]{30\cdot9m.} Ra^{222}_{88} \xrightarrow[\alpha]{38s.} Em^{218}_{86} \xrightarrow[\alpha]{0\cdot019s.} RaC'^{214} .$$

The Actinides

Chemically, the new elements neptunium, plutonium, americium and curium are believed to form part of a new series, known as the actinides, analogous in the arrangement of their extra-nuclear electrons to the rare earths (the lanthanides). Starting probably with thorium, successive elements gain an electron in the $5f$-shell, which in the case of curium contains seven electrons and is half full (just as the $4f$-shell is half full in gadolinium). The physical evidence for this hypothesis is far from complete: some indication is given by optical and X-ray spectra and by magnetic measurements, while some of the actinide ions in solution have sharp absorption bands, which would be expected if transitions occurred in a shielded inner shell. X-ray studies of a number of compounds of the actinides have also been made and show a contraction in ion size as the series is ascended, which is similar to the lanthanide contraction for the rare earth ions. This is seen in Table 1, where the lanthanide contraction is also illustrated.

Table 1. Crystal radii of actinide and lanthanide ions

No. of *f*-electrons	Crystal radii of ions (A.)					
	Thoride series		Actinide series		Lanthanide series	
0	Th^{4+}	0·95	Ac^{3+}	1·11	La^{3+}	1·04
1	Pa^{4+}	(0·91)	(Th^{3+}	1·08)	Ce^{3+}	1·02
2	U^{4+}	0·89	(Pa^{3+}	1·06)	Pr^{3+}	1·00
3	Np^{4+}	0·88	U^{3+}	1·04	Nd^{3+}	0·99
4	Pu^{4+}	0·86	Np^{3+}	1·02		
5	Am^{4+}	0·85	Pu^{3+}	1·01	Sm^{3+}	0·97
6			Am^{3+}	1·00	Eu^{3+}	0·97

The valencies of the actinide elements are shown in Table 2, together with those of the corresponding rare earths.

Table 2. Valencies of the actinides and lanthanides

Element	Valencies	Element	Valencies
Ac	3	La	3
Th	4, (3), (2)	Ce	4, 3
Pa	5, 4	Pr	5, 4, 3
U	6, 5, 4, 3	Nd	(4), 3
Np	6, 5, 4, 3	Tc	3
Pu	6, 5, 4, 3	Sm	3, 2
Am	4 or 5, 3, 2	Eu	3, 2
Cm	3	Gd	3

Values are in some cases higher than for the rare earths, which reflects the looser binding of the 5*f*-electrons and their more ready promotion to the valency shell. Between uranium and curium there is an increase in stability of the lower valency states, and it is remarkable that americium can be reduced by sodium amalgam to the bivalent state, which resembles the corresponding states of samarium and europium. Both americium and curium resemble the rare earths rather closely, and are best separated from them by the use of ion exchange resins. Numerous compounds of the new actinide elements, and of plutonium in particular, have now been described, and, although their radioactivity and the resulting need for special facilities may render them inaccessible to most laboratories, the chemistry of these substances will undoubtedly shortly be as well known as that of most other elements.

Much less has been published as yet on the chemistry of francium, astatine, prometheum and technetium, the other four new elements mentioned earlier. Astatine in the form of the isotope At^{211}_{85}, an α-active substance of 7·5-hr. half-life, has, however, been used in tracer studies which have given a general picture of its chemistry. The element itself may be extracted from solution with organic solvents and thus resembles iodine. There is also definite evidence from ion migration experiments that it can form negative ions, which are probably analogous to the iodide and iodate ions. The intense α-activity of astatine will, however, render the study of its chemistry on anything approaching a macro scale a matter of very great difficulty. The missing rare-earth element of atomic number 61 has now been clearly identified by its X-ray emission spectrum. It is formed in fission and also in cyclotron reactions, and has been separated with the aid of ion exchange resins. There is, however, no reason to expect that the chemistry of the element will differ substantially from that of the other rare earths. In the case of technetium, at least milligram quantities of one of the long-lived radioactive isotopes have already been prepared, and, in view of its position between manganese and rhenium in the periodic table, the element and its compounds are likely to be of very great interest to the chemist.

BIOCHEMICAL ASPECTS OF GENETICS

It was often emphasized by the late Sir Frederick Gowland Hopkins that a study of the individual cell and of the organisation of chemical reactions within the cell was the true objective of biochemistry. The relationship of genetic constitution to chemical activity is, in such a connexion, a matter of first importance; but it was not until some ten years ago that investigations of this nature could be applied experimentally to unicellular organisms. Following a proper advance in technique, derived largely from the work of Beadle and Tatum, corresponding advances have taken place in the elucidation of genetico-biochemical problems.

The symposium organised recently by the Biochemical Society upon "Biochemical Aspects of Genetics" would have delighted Hopkins, for he was convinced that in this direction lay the biochemistry of the future. Sufficient indication was available from the pioneer work of such investigators as Garrod and Onslow on multicellular organisms that there awaited a rich harvest to be gathered in the fullness of time, and the discussion here reported has further endorsed such an expectation.

The symposium was so organised that in the morning session, under the chairmanship of Prof. J. B. S. Haldane, the development was reviewed of our knowledge of colour inheritance and pigment production in flowers and the interpretation of chemical abnormalities encountered in man. The afternoon session, under Dr. A. Neuberger, dealt with chemical methods of inducing mutation, the relation between gene action and mutation, between spatial pattern as the geneticist understands it and the time sequences of biochemical processes, and finally with the problem of the relationship existing between genetic differences and the production of adaptive enzymes in micro-organisms. A wide field was thus covered, which served to point to problems for future resolution as well as frequently to indicate striking identity of conclusion by workers in the biochemical and genetical laboratory respectively.

That a simple relation must exist between genes and enzymes is, of course, an assumption essential to all this work on biochemical genetics; but the exact form of such relationship has still to be determined —whether, for example, one particular gene controls the elaboration of one particular enzyme, or whether the gene itself may not, indeed, be identified with the enzyme in question. The bulk of experimental and clinical evidence is in favour of the former one-to-one hypothesis; but it seems that the question of identity, or otherwise, may not be finally answerable until we know much more concerning the nature of adaptive enzymes and the mechanism of their formation.

Considering now in more detail each of the contributions to this symposium, W. J. C. Lawrence described how Onslow's suggestion that in *Antirrhinum majus* anthocyanins were derived from anthoxanthins led to the later investigations at the John Innes Institution which demonstrated that anthocyanin production was controlled as regards amount, state of oxidation, degree of methylation and glucosidal type by simple gene relationships, as were also flavone and chalkone production. Further, it was shown that in *Dahlia*, competition could exist between the production of anthocyanin, flavone and chalkone, according to gene dosage, implying the parallel production of these materials from a common precursor, a view which had previously been put forward on purely theoretical grounds by Robinson.

Prof. L. S. Penrose set forth Garrod's fundamental conception of certain disease states or metabolic anomalies as inborn errors of metabolism, and showed how such an analysis enabled an explanation to be given for the first time by Garrod of the special significance of inbreeding in man.

Prof. C. Rimington pointed out that Garrod's interpretation of familial conditions as being due to the lack of a particular enzyme essential for the completion of a certain stage in normal intermediary metabolism is probably correct in the case of alcaptonuria, and cited good evidence for believing tyrosinosis and phenylketonuria to be similarly interpretable. In familial methæmoglobinæmia, deficiency of a co-enzyme factor in the erythrocytes of affected persons has actually been demonstrated by Gibson. Certain of the conditions studied by Garrod, notably cystinuria, are better interpreted, however, as errors of retention or excretion. Thus cystine is only one of a group of substances showing some chemical similarity which are demonstrable in cystinuric urine, and it would appear that in this condition the kidney is unable to re-absorb certain constituents from the glomerular filtrate. A precisely similar explanation has been given by Friedman and Byers for the excretion of uric acid by the Dalmatian dog, and these workers produce compelling experimental evidence in support of their view.

The different classes of substance which are available for the chemical induction of mutation—mustards, carcinogenetic hydrocarbons, etc.—were discussed by Dr. J. G. Carr, who pointed out that all are radiomimetic. As yet no substances have been discovered which will react with only one gene.

Dr. D. G. Catcheside analysed the relationship between gene action and mutation. Some extreme mutations, in which loss of activity appears to be complete under all conditions within which the organism is viable, can back-mutate or revert to the wild type. This must mean that an almost intact gene, capable of reproduction, must have persisted. The most probable postulate is that specificity has been retained, but that the enzyme produced by the mutant gene suffers from a restricted stability, for example, as regards temperature or pH. In other cases back-mutations never occur.

Dr. G. Pontecorvo, after describing the modern techniques for the genetical study of moulds, bacteria, protozoa, etc., posed the question whether or not spectral organisation of genetical architecture is related to the time sequence of biochemical steps it controlled, in some such way as are operations along assembly lines. There is some suggestion that this may be so, but further specifically planned investigation is needed to prove this point.

In the concluding contribution, Dr. J. Monod dealt with the phenomenon of adaptation encountered in bacteria, and showed how, for example, in *E. coli* ML, a lactose-splitting enzyme, lactase, and a maltose-splitting enzyme, amylomaltase, may be induced to form within the cells by cultivating them upon the respective substrates. The same two enzymes are subject to genetic control, as is seen from spontaneous and induced mutations. These latter are independent of the state of adaptation of the cells.

It is clear that much remains to be done before such fundamental processes of the cell as those under discussion at this symposium are fully understood, but that already biochemistry and genetics have joined in a partnership from which both are bound to profit immeasurably. C. RIMINGTON

THREE HISTORICAL NOTES

By DR. D. McKIE
University College, London

Boyle's Library

THE Hon. Robert Boyle died on December 30, 1691, and some curiosity has been expressed from time to time in recent years about what was done with his books after his death. In that valuable bibliographical study of Boyle that has made every student of seventeenth-century science his debtor, Prof. John Fulton quoted an entry for April 1, 1692, from a diary, now in the Bodleian and possibly by Zachary Merrill, to the effect that Boyle's library contained "330 fol. 801 qtos. 2440 Oct and 12. most of y^m well bound. They may be had for 3 or 400£ (tho' worth 1000) because they must not be sold by Auction"[1]. It was a considerable collection. Later, Fulton quoted[2] a further reference through the discovery by Mr. J. C. Hindle, of the Bodleian, of an advertisement dated July 9, [1692], stating that: "The Library of the Honourable Robert Boyle, Esq; lately Deceased, will be sold by Retail, on *Monday* the *11th.* of this Instant *July*: Any Gentlemen or Others, may have the opportunity to View, and Buy what they please, at reasonable Rates. Attendance will be given at the late Lady *Ranelaugh's* House in the *Pell-Mell*, near St. *James's*, on *Monday*, *Tuesday* and *Thursday* next, from Nine a Clock in the Morning till Seven at Night." In explanation of the reference to "Pell-Mell", it is known that Boyle lived with his sister, Lady Ranelagh, in her house in Pall Mall; she predeceased him by a week.

From this announcement, says Fulton, the library was not sold until July 1692, and then not by auction, but privately. It would seem, therefore, that booksellers and others were invited to buy from the collection lots or items in which they were interested.

Recently a copy of Becher's "Novum Organum Philologicum" (Francofurti ad Mœnum, 1674) came into my hands with the inscription on the reverse of the fly-leaf, "R Hooke p^d 21^d. Mar.25.1693MF.", since verified as being in Hooke's handwriting. Reference to the fragment of Hooke's diary for 1688–93 confirmed the details of the inscription; for under that date he had recorded, "In MF Paid 1.9d for Bechers *Novum Organum philologicum*"[3]. Further reference to the diary for the same period brought to light a number of other interesting entries which indicate that Boyle's library was dispersed.

Two days before he bought Becher's book, Hooke "in MF saw many of Mr Boyles German chemicall books, also Bechers word-book"[4], which suggests that this copy of Becher's book may well have belonged to Boyle before Hooke, since Becher was a well-known writer on chemistry and since it was a scientific book, a kind of thesaurus of scientific terms in Latin and German. Boyle did not, so far as is known, have a book-plate and he did not inscribe his name in his books.

Four days previously, on March 21, 1693, Hooke wrote: "In MF I saw neer 100 of Mr Boyles high Dutch German Chymicall books ly exposed in Moorfeilds on the railes . . ."[5]. It seems, therefore, that some at least of Boyle's books were sold to a bookseller in Moorfields. Later, at Tom's coffee-house, Hooke, on March 28, 1693, "Read a *Catal.* of Morgans and Boyles books at Toms"[6]. Next day, he called at Tom's for a catalogue "for Mr Waller".

These entries by Hooke make it practically certain that Boyle's library was dispersed and that there is no hope of its now being recovered, as Newton's was.

The Descent of Pierre Joseph Macquer (1718-84)

Pierre Joseph Macquer (1718–84), compiler of the first dictionary of chemistry and professor of chemistry in the Jardin du Roi, is said to have been descended from a noble Scots family who had lost all for the Stuart cause and the Catholic faith. Macquer does not, however, seem to be a corruption of a Scots name; even if it were derived from Ker, the noble families of that name were not supporters of the Stuart cause[7]. It appears that Macquer's family came to France, not after the rising of 1715, but with James II in 1689 [8]. This would suggest the possibility of an Irish origin.

Search in the parish registers of St. Germain-en-Laye, the refuge of James II and his Court, reveals the name of Maguire, the family name of Lord Enniskillen, and in various spellings such as Magoire, Mackower, Magower, Makaire, Magaire and other forms, as well, of course, as the correct one[9]. In most cases the entries relate to members of the ill-fated house of Enniskillen. The peerage had been forfeited in 1645, when Connor, second baron, was hanged at Tyburn for his share in the rebellion (1641) of Owen Roe O'Neill. The family continued to use the title, and Roger, fifth baron, was appointed Lord Lieutenant of Fermanagh by James II in 1689.

The curious varieties of spelling in the registers of St. Germain leave no doubt of the possibility of the corruption of Maguire to Makaire. French pronunciation would make no difficulty in corrupting Maguire to Macquer. In fact, the Irish officer, Richard McGuire, who was associated with Richard Crosbie (1755–1800), the first Irish aeronaut, is described by Tissandier as "un jeune aéronaute nommé Quer"[10].

The established corruption in spelling and the descent from a noble family suggest, therefore, that Macquer may have been a descendant of the Maguires, Barons of Enniskillen, and of Irish, rather than Scots, origins.

Sir Thomas Browne and Biringuccio's "Pirotechnia"

The recent publication of a complete English version of the "Pirotechnia" (1540) of Biringuccio[11] has once again raised the question of the currency of this work in earlier times, and the alleged preference for the "De Re Metallica" (1556) of Agricola. The translators directed attention[12] to an entry in Hooke's diary for November 12, 1675 [13], referring to Biringuccio's treatise, but pointed out that known references to this great book are few. Another is, however, to be found in Hooke's diary under the date March 1, 1677/8, when Hooke acquired a copy for two shillings[13]. Attention is also directed to a further reference by Sir Thomas Browne in his "Hydriotaphia" (1658)[14], where he refers to the preservation of charcoal underground for more than four hundred years as described by Biringuccio[15].

OBITUARIES

Prof. C. H. Lander, C.B.E.

Cecil Howard Lander was born at Stockport, Cheshire, in 1881. After receiving his early education at private schools in Cheshire, he decided to prepare for engineering as his career. His first step was to obtain practical training. To this end, on leaving school, he joined the engineering staff of the Manchester Ship Canal Company, then moved to become an assistant to the late Mr. Charles Hopkinson, and eventually was on the staff of Heenan and Froude, by whom he was employed on the design and testing of refuse destructors. In consequence, Lander had acquired a background of varied practical experience over about five years before he entered the University of Manchester in 1902 as a student in engineering. At the University his ability was soon recognized. He graduated in 1905 with first-class honours and was awarded the Fairbairn Prize.

On graduation, Lander continued as a research student. A year later he was appointed a demonstrator, and in 1910 was promoted to a lectureship in engineering in the University of Manchester, a post which he held until he joined the R.N.V.R. in 1916. Lander's research work while he was in Manchester included a series of investigations on problems of heat flow, surface friction and allied phenomena, on the results of which he was awarded the degree of M.Sc. in 1908 and D.Sc. in 1916. During this period he was also a part-time engineer to the Home Office in charge of experimental work on heating and ventilation for the Humidity Committees; this work was the basis of regulations since included in the Factory Acts.

During 1916–20 Lander served as a lieutenant in the R.N.V.R., and his important work in relation to several war-time requirements was recognized by an award on the recommendation of the Royal Commission on Awards to Inventors. On leaving the R.N.V.R. in 1920, Lander was appointed assistant to the director of fuel research (the late Sir George Beilby) in the newly established fuel research organisation of the Department of Scientific and Industrial

Research. Two years later he was promoted to the post of deputy director and in 1923, on the retirement of Sir George Beilby, he became director of fuel research, a post which he held until 1931. Under his guidance the fuel research organisation undertook important investigations on the carbonization and gasification of coal and coke, on the production of oil from coal by hydrogenation, and on many other fuel problems. In association with the late Dr. F. S. Sinnatt, he organised and developed the Physical and Chemical Survey of the National Coal Resources. In recognition of his work as director of fuel research, Lander was made a C.B.E. in 1928.

In 1931 Lander returned to academic life as professor of mechanical engineering at the Imperial College of Science and Technology, London, a post which he held with distinction until 1946. Under his guidance, based on his broad experience and deep interest in education, a high standard in the training of mechanical engineers was achieved. He also played a prominent part in the systematic training of chemical engineers, and was the first chairman of the Board of Studies in Chemical Engineering in the University of London. The branch of research in which he was most keenly interested was that in relation to problems of heat transfer, on which he led and inspired teams of investigators for more than twenty-five years. His notable papers on the subject included that which he presented to the Institution of Mechanical Engineers in 1942, and for which he was awarded the Hawksley Gold Medal and Premium.

During the Second World War, Lander's experience and ability were invaluable. He played a great part in the development of gas turbines and jet propulsion, flame-throwers, and oil burners (F.I.D.O.) for the dispersion of fog over airfields. His merit in this kind of work lay not only in the way he guided and inspired investigators under his immediate control, but also in the facility with which he co-ordinated the work of several teams under different leaders and ensured harmonious co-operation from all in achieving results rapidly.

Of the many organisations indebted to him for advice and help, only a few can be mentioned as examples. He was for many years vice-chairman of the British National Committee of the World Power Conference, a member of the Safety in Mines Research Board, a member of the Mechanical Engineering Research Board of the Department of Scientific and Industrial Research, and chairman of several wartime scientific committees. For two years, 1946–48, he was president of the Institute of Fuel and was awarded the Melchett Medal of that Institute in 1945.

On retiring from the professorship of mechanical engineering at the Imperial College in 1946, he accepted an invitation to become dean of the Military College of Science at Shrivenham, with the task of re-organising the College as the principal establishment for training army officers in the military applications of science and technology. In this new sphere of activity, Lander had already achieved notable success. It was while he was engaged on this work that Lander died suddenly at Shrivenham on March 17.

Apart from his professional work, Lander had other interests, including music; and he had looked forward to spending more time at his house at Shepperton and with his motor launch on the Thames. Of a kindly nature, he will be missed by his many friends and colleagues. A. Parker

In October 1946, Dr. Lander became dean of the Military College of Science, which was re-assembling after the War at Shrivenham in Wiltshire and was expanding its scope to prepare officer students for external degrees in science and engineering of the University of London as well as to train officers for the technical staff of the Army.

The re-organisation necessary to enable the College to carry out these extended functions at the same time as it was being reconstituted involved an enormous amount of work in the remoulding of the faculties, in discussions with the University of London, in the preparation of syllabuses and in the recruitment of lecturing staff. The co-ordination of this work in the College fell upon Dr. Lander, and his energy and enthusiasm and his connexions with the University contributed in great degree to the reconstitution of the College. That within two and a half years of its re-opening the first technical staff course passed out and the first degree courses took Part I of their degrees at London was largely due to his untiring work.

His wide contacts with the academic world resulted in the best of advice being available to the College, and his strong support of a policy of insistence upon high academic standard has laid sound foundations for the future.

Apart from his work on the academic side, Dr. Lander was a keen supporter of the sports and cultural activities of the College. He was a leading performer in the Musical Club and led the College orchestra.

But the quality by which he will be most remembered in the College was his kindly wisdom. In an assembly of soldier students and of academic and soldier teachers, most problems are viewed from several points of view and divergent opinions are strongly held. That varying opinions have been reconciled and canalized into channels which furthered the objects of the College has been in no small degree due to Dr. Lander's unfailing wisdom. His counsel both in wider policy and in day-to-day detail was invaluable, and the Military College of Science will look back on its first dean, with feelings of gratitude and deep affection, as one of the main founders of its modern constitution. W. J. Eldridge

Mr. H. E. Hadley

Mr. H. E. Hadley, well known as the author of many elementary text-books of physics, died on March 6, at the age of eighty-two. Mr. Hadley had lived rather a retired life. He was appointed headmaster of a small science school in Kidderminster, where he combined with physics a lectureship in chemistry. In those days, physics was considered of less importance than chemistry; but Mr. Hadley was always at heart a physicist. In spite of the almost total lack of physical apparatus, he made physics the career of three of his early pupils, for in three successive years his students gained national scholarships at the Royal College of Science, London, now the Imperial College of Science and Technology, a rather unique success for a small school.

Mr. Hadley was a contemporary of Sir Richard Gregory and H. G. Wells at the same College, and from his training there and association with C. V. Boys he acquired a special genius for making his own physical apparatus. His teaching equipment at Kidderminster was largely of his own making, and it would seem that this gave physics an added attraction to his students. Evidence of his ingenuity in this direction is apparent in his books.

In 1898 he wrote his first text-book, on "Magnetism and Electricity for Beginners". This was the first of several text-books produced in association with Sir Richard Gregory, which are known to generations of physics students. Much of his time thenceforward was devoted to the preparation of these books, while he still continued his teaching, from which he only recently retired after a period of more than fifty years. He maintained his interest in his books to the end, devoting much care to keeping them abreast of modern developments.

Mr. Hadley had a charming personality, and he was regarded with affection by those who benefited from his instruction.

W. S. TUCKER

WE regret to announce the following deaths :

Mr. Will Hay, well known as an actor and also a distinguished amateur astronomer, on April 18, aged sixty.

Mr. R. A. Todd, a Ministry of Agriculture and Fisheries inspector and formerly a member of the staff of the Plymouth Laboratory of the Marine Biological Association of the United Kingdom.

NEWS and VIEWS

Meldola Medal for 1948 : Dr. R. A. Raphael

ON the recommendation of the Council of the Royal Institute of Chemistry, the Society of Maccabæans has awarded the Meldola Medal for 1948 to Dr. Ralph Alexander Raphael, in recognition of the contributions he has made to the investigation of new methods of approach to the synthesis of natural compounds. Dr. Raphael graduated in 1941 from the Imperial College of Science and Technology with first-class honours in chemistry, and in 1943 was awarded a Ph.D. for work on acetylenic compounds. During 1943–46 he was head of one of the chemotherapeutic research departments of Messrs. May and Baker, Ltd., and was mainly concerned with penicillin chemistry. He was then awarded an Imperial Chemical Industries fellowship and resumed research work at the Imperial College on the investigation of the potentialities of acetylenic compounds in the synthesis of natural products. In 1947 this work resulted in the total synthesis of the penicillic acid, thus proving its structure beyond doubt. Attention was then turned to the utilization of the peculiar properties of acetylenic compounds to accomplish the synthesis of carbohydrates and their derivatives, and, up to the present, arabitol, ribitol, erythritol, threitol and erythrulose have been obtained. A study is also being made of methods of producing long-chain aliphatic acids of various types. Concurrently, Dr. Raphael is also investigating synthetic routes to compounds containing the vitamin D triene system. He has recently been appointed lecturer in organic chemistry in the University of Glasgow.

Avenue of Human-headed Sphinxes at Luxor

IT has long been known that the avenue of ram-headed sphinxes of Amenophis III which extends southwards from the Temple of Khons at Karnak is the northern end of a processional way once linking the Temple of Karnak with the Temple of Luxor about one and a half miles to the south. On the line of this avenue, Zakaria Effendi Ghoneim, chief inspector of antiquities for Upper Egypt, has recently found a further series of human-headed sphinxes erected by either Nectanebo I or II about a thousand years later, in the late fourth century B.C. The main interest of the new discovery appears to lie, for the moment at least, in the inscriptions on the base of each sphinx. The text records that Nectanebo had "made this road for Amun so that he might make good navigation from Luxor". The god Amun was normally resident at Karnak. The principal occasion on which he visited Luxor was during the annual festival of Opet, when he was conveyed by river from Karnak to Luxor and the whole city was given over to festivity for many days. The new texts, therefore, either hint that by the end of the Pharaonic period the river journey of Amun during the Feast of Opet had been replaced by a progress by land, or they refer to a new or unidentified Theban feast. As the clearance and excavations round the Temple of Luxor progress, there is every reason to expect that new discoveries will be made, and that fresh light will be thrown on the early history of Thebes.

Additional Remains of *Australopithecus* in South Africa

FURTHER discoveries of the remains of the fossil Australopithecinæ of South Africa are now reported from a new site, Makapansgat, almost 250 miles north of Sterkfontein, where Dr. R. Broom found numbers of skulls and portions of the limb skeleton during 1947 and 1948. Two of the Makapansgat specimens, which have already been described by Prof. R. Dart in the *American Journal of Physical Anthropology* (6, 259 and 391 ; 1948) and referred by him to a new species, *A. prometheus*, consist of an occipital bone and an immature mandible. These provide additional confirmation of the inferences based on the earlier material that the Australopithecinæ show in certain anatomical features a remarkable approximation to those hitherto regarded as distinctive of the Hominidæ. For example, the disposition and extent of the nuchal crest and muscular markings on the occipital bone conform to the human rather than the simian type. The perfectly preserved and unworn anterior premolar in the immature mandible is bicuspid with the cusps of approximately equal height as in man, and thus differs markedly from the characteristic sectorial form of the lower anterior premolar in the anthropoid apes. Still more recently, there have been found at the same site a considerable part of the facial skeleton, a parietal bone, and the iliac portion of a pelvis. According to unpublished reports, the ilium, like the specimen already described by Broom (*Nature*, 160, 430 ; 1947), is closely similar in shape and proportions to a human ilium, and thus contrasts strongly with that of apes.

Science Museum, London

DEMOLITION of the old portion of the Science Museum, London, known as the Southern Galleries, has now commenced. This building, which had recently become extremely dilapidated, was erected as a temporary structure for the International Exhibition of 1862, and continued to be used thereafter by the Science Museum for exhibition purposes until the beginning of the War in 1939. For many years these galleries have been scheduled for destruction, and owing to their susceptibility to fire and bomb damage were a source of considerable anxiety during the War. The main portion of this old building is now being demolished to make room for a new centre block for the Science Museum, on the roof of which a planetarium is to be erected. It is anticipated that the ground floor and basement of this new building will be available in time to accommodate the science and technology portion of the Festival of Britain Exhibition in 1951. After this, work on the building will be continued and the building when completed will form the centre block of the Science Museum, with four floors of exhibition galleries. Arrangements for the occupation of this portion of the Science Museum are well under way, and it is anticipated that long before this additional accommodation becomes available, detailed arrangements for the display of specially appropriate and attractive exhibits will have been completed.

Scientific Instruments of George III

While he was still Prince of Wales, the future King George III showed much interest in mechanics, optics, astronomy and scientific experiments of all kinds. Thus encouraged, the leading instrument makers of the second half of the eighteenth century constructed many models and apparatus for the instruction of the Prince. As might be expected, these models illustrate the craftsmanship of the period, and collectively they convey a remarkably clear impression of the general field of scientific study and experiment at that time. Fortunately, the instruments were preserved as a collection, and for many years they were kept at Kew Observatory. They were used again for instructing the many children of George III, and in 1841 they were presented to King's College, London. The collection was loaned to the Science Museum in 1926, but since 1928 it has been in store on account of the lack of space. It has now been placed on exhibition again and may be seen, until the end of September, at the Science Museum, South Kensington, London, S.W.7. Historically, the exhibition is of interest, as it covers an important era in scientific development—an era which witnessed the growth of modern physics and chemistry from the 'black magic' and haphazard alchemy of the Middle Ages, the development of such instruments as the thermometer, and great advances in the study of electricity. Science was becoming popular, but at the same time the foundations were being laid for progress on logical lines of experimental and theoretical philosophy. The course of instruction and the experiments performed tended to follow closely the lines laid down half a century earlier by the Dutch philosopher 'sGravesande, himself a disciple of Sir Isaac Newton, and one of the gems of the present exhibition is the 'Philosophical Table', which is similar to that designed by 'sGravesande. In the parlance of this more vulgar age, a 'philosophical table' is a 'laboratory bench'. Other items worthy of special note are the vacuum pumps made by George Adams and two fine microscopes constructed about 1750.

Commission on South African Museums

Last year, in *Nature* of November 27, p. 861, it was reported that the Government of the Union of South Africa had set up a Commission to inquire into the financial position of certain State-aided institutions which, it was then understood, included certain museums, art galleries and zoological gardens. An announcement in the *Government Gazette* (*Pretoria*) for March 4 of this year extends the field of inquiry, and lists the institutions concerned, as follows: the South African Museum, Cape Town; the Transvaal Museum, Pretoria; the Natal Museum, Pietermaritzburg; the Orange Free State Museum and Monument Museum, Bloemfontein; the Voortrekker Museum, Pietermaritzburg; the South African War Museum, Johannesburg; the South African National Art Gallery, Cape Town; the Michaelis Collection, Cape Town; the National Zoological Gardens, Pretoria; and the National Botanical Gardens, Kirstenbosch.

The inquiry now covers not only the financial aspects of these institutions, but also their organisation and activity. The Commission is directed to make investigations and recommendations regarding the co-ordination of the research carried out by each institution; the possibility of co-operation between the named institutions, universities and other institutions towards a greater economy and efficiency in the preparation of material for exhibition and educational purposes; the advisability of forming a national board of trustees, or similar organisation, for the co-ordination of the work of the named institutions; the advisability of co-ordinating the research and education functions of the institutions and certain others not State-supported; the advisability of all or some of the named institutions becoming full State institutions; the incorporation of war museums in other museums; and the establishment of a science museum in Johannesburg. If the Commission finds that the last-mentioned is desirable, it is asked to make recommendations for its organisation and control. For the purpose of the inquiry outlined above, the Commission is given full authority to consult any person and Government book, record, etc. The wide scope of the inquiry and its importance demonstrate the formidability of the Commission's task, and it is indicative of a strong Government interest which will ultimately not only strengthen the efficiency of the Union's museum services, but will also point the way to even further developments.

Survey of India: Annual Report

The Survey of India has issued a Civil Activities Report covering the period April 1, 1945–March 31, 1946, which replaces the detailed General and Geodetic Reports which have been in abeyance since 1939 but are to be introduced for the year 1946–47. Much of the work of the Survey during the year was directed towards the furtherance of a number of long-term projects, such as the Kosi, Mahanadi and Tista irrigation schemes. For these schemes somewhat rigid priority assessments had to be made owing to the shortage of men and instruments, and new and cheaper survey expedients were adopted to provide preliminary information. Even so, the routine topographical programme received scant attention. With the widespread resumption of civil surveys, the concentration of resources in Dehra Dun has been reversed, and the Eastern Circle controlling work in Assam, Bengal, Bihar and Orissa has been re-established in Shillong. The Southern Circle has been re-created; but map publication is still largely concentrated in Dehra Dun, where also the projects officer is located. No new or revision topographical surveys or forest surveys were carried out during the year; but two settlement surveys were undertaken in the hilly districts of Kulu and Almora. Considerable progress has been made in replenishing stocks of quarter-inch maps corrected up to date; but for one-inch maps the present policy is to reprint the maps uncorrected pending the opportunity for surveying the necessary corrections. The series comprises 4,100 sheets, and in issuing corrected editions a start will be made with the most developed regions.

War experience as well as post-war activities have shown the need for a strong scientific body largely free from administrative responsibilities to enable the Survey of India to keep abreast of scientific thought and developments. The proposed Survey Research Institute, replacing the War Survey Research Institute, when constituted, will carry out the scientific functions of the Survey, and will also collaborate with the National Physical Laboratory, particularly in respect of standards of length and time. The Institute will be staffed and organised for work on measurements of length; standardization of measuring tapes, etc.; astronomical work as applied to latitude, longitude and time; tidal work; and magnetic observations. During the year the War Survey Research Institute carried out further investigations on the improvement of base-measurement apparatus and devised new methods of rapid fixation of position from stellar observations.

Linen Research Association: Report for 1948

THE Linen Research Association, which is at Lambeg, Co. Antrim, has recently issued its annual report for the year ended September 30, 1948. The report records the opening of the new buildings in June; the installation of plant and equipment in the new technical shed for bleaching, dyeing and finishing is now almost complete. Delivery of machinery for the weaving section has also begun; but difficulties in recruiting well-qualified scientific staff have continued, although the accommodation for the increased staff planned in 1945 is now available. In view of the fall in home flax production, it is considered essential to continue research on flax production and to make another serious attempt to increase the yield of flax obtained from scutching. The total number of members is now 280, and the report includes lists of both members and staff and of the membership of committees. Research work carried out during the year has included a continued study of the effect of varying the retting process on the yield and quality of fibre produced from different types of straw, and also a study of the prevention of deterioration of the retted straw during drying. An investigation on a standard turbine scutching-machine has shown that low humidity has little effect on yield provided the straw contains about 14 per cent of moisture, but it greatly reduces the yield if the straw is dry; while at 85–90 per cent relative humidity in the turbine, dry straw can be scutched with a yield only slightly lower than that with properly conditioned straw. The investigation for the Ministry of Supply on the relation between fibre properties and yarn quality has been completed, and an investigation of 'dropped ends' has been started to determine the factors which limit the rate of production and the efficiency of spinning frames. Weaving tests have continued on a variety of yarns in automatic looms of the shuttle-change and pin-change types. Work on cloth bleaching has aimed at modifying existing processes to whiten fabrics with no degradation of the cellulose, and to secure the maximum durability; while work on dyeing has led to an improved method of securing penetration of vat dyes in linen fabrics.

Analysis of Management

IN his paper, "The Nature of Management", based on an address to the London and District Society of Chartered Accountants, and now issued as "Occasional Papers No. 2" by the British Institute of Management, Sir Charles Renold insists that management is directed to action and that the action is at second-hand: management is concerned with guiding the actions of people other than the planners or guiders. Accordingly he regards management as fundamentally the process of getting things done through the agency of a community, and the functions of management as the handling of a community with the view of its fulfilling the purposes for which it exists. A large part of those functions is, in fact, concerned with the well-being of the team or community, and, in pursuing that well-being, the particular purpose of the community may be only of very indirect consideration. Sir Charles examines in some detail the requirements of community well-being so far as they are yet understood, emphasizing the importance not only of the structure or organisation of the community and procedures but also of their acceptance by the individuals forming the community. Contentment will not be secured unless there is confidence that rules and discipline are administered fairly, and the processes of using the team or community to achieve its purposes really turns on devising instructions appropriate to the situation. Planning he regards as a group of processes providing the raw material from which operative instructions are fashioned, and control as seeing how the plans are working out with the view either of modifying them or of improving the response of the community when necessary. Accountancy is one of the indispensable techniques of management; but he points out that every official in the course of his executive duties has to make decisions which are of the nature of policy, and the readiness to accept responsibility for making such decisions and the ability to make wise ones are as important elements in the qualifications of an official as is loyal compliance with orders. The statement that policy-making is the business of the board of directors and execution that of the management should not be accepted uncritically; and Sir Charles distinguishes policy-making as the establishment (not necessarily the origination) of an overall pattern of rules and principles from the development of these rules and principles into greater detail, and execution as their application to particular situations.

Problems in Astronomy

THE Cawthron Lecture for 1947, with the title of "Problems in Astronomy, Solved and Unsolved", was delivered by F. G. Gibbs, curator of the Atkinson Observatory, Nelson, N.Z., and gives a very useful survey of the progress of astronomy during the last two decades. Some space is devoted to an examination of the theories of the source of stellar energy, and a short description is given of Bethe's carbon-cycle theory which is now generally accepted. A consideration of variable stars leads to the past history of the sun, the heat of which has been shown by geological evidence to have varied considerably during the last 1,000 million years. Simpson's pluvial theory is dealt with—a theory which assumes that increased precipitation of moisture in the form of rain and snow was due to an increase in the heat of the sun—but no satisfactory explanation has yet been given of the cause of the variation in the sun's heat. Regarding novæ and super-novæ, no explanation is suggested beyond the statement that "atomic energy has no doubt something to do with it". Among some of the problems still awaiting solution are the origin of the solar system, the evolution of the stars, the structure and evolution of the universe, and cosmic rays. This lecture provides a very helpful summary of the progress of astronomy in comparatively recent times and also of the problems still awaiting solution, some of which appear more intractable now than they did twenty years ago.

Royal Scottish Museum : Natural History Department

With the re-opening of the Beasts of Prey Hall, the main halls and galleries belonging to the Natural History Department of the Royal Scottish Museum, Edinburgh, are now available to the public. These number twelve in all, allocated as follows : British fauna (2), mammals (3), extinct animals (1), foreign birds (1), amphibians and reptiles (1), fishes and molluscs (1), entomology (1), biology (1), and children's gallery (1). In addition, the study room, for use of students of the collections, is now open. During the War, many of the collections were removed, and the opportunity has now been taken to re-arrange much of the material. In addition, two specialist galleries for students are in use. An introductory hall entitled "The Story of the Earth", serving as an introduction to natural history and geology, is in course of preparation. A gallery of marine invertebrates is projected.

Universal Decimal Classification

The first abridgment of the full universal decimal classification in English has been published by the British Standards Institution as B.S. 1000 A. : 1948. It consists of 128 pages and costs 25*s*. It is intended for use in libraries or private collections where detailed subdivision of subjects is not required, or in special libraries using the full classification in a given subject but requiring an abridged classification for other fields. It is based on the official abridgment in the Dutch language, fifth edition, with the help, mainly in the sciences, of the abridgment published by H.M. Stationery Office, under the title "Classification for Works in Pure and Applied Science in the Science Museum Library", third edition. The abridgment should form a useful introduction and guide to the complete fourth edition in English, which is being published by the British Standards Institution, section by section.

Correction of Magnesium Deficiency in Tomatoes

Magnesium chlorosis is widespread among tomatoes grown under glass in Great Britain. It probably causes a considerable loss of yield, and economic methods for its correction are therefore urgently required. D. J. D. Nicholas shows (*J. Hort. Sci.*, 24, No. 1, 1–18 ; June 1948) that this can best be accomplished by sprays of two per cent of magnesium sulphate applied to the foliage five times at intervals of two or three weeks. This results in the application of less than 5 cwt. per acre, compared with 10–20 cwt. of calcined kieserite, found necessary for soil applications. Soil factors probably immobilize a large proportion of the soil dressings of magnesium sulphate. Interactions of magnesium with potassium and nitrogen are also discussed in the paper.

Chelsea Polytechnic

The fifty-third annual report of Chelsea Polytechnic is interesting because of the attractive way in which its items have been presented. Besides the usual information about the number and range of classes and examination successes, the report contains a detailed analysis of the occupations of evening students, the geographical distribution of students, the kind of research undertaken by advanced students and particulars of services rendered by members of the staff in a voluntary capacity to various kinds of learned and other societies. The examination statistics show that, during the last two years, one D.Sc., five Ph.D.s and seventeen M.Sc.s were obtained, figures of considerable significance for those who wish to see some evidence that the recommendations of the Percy Committee on Higher Technological Education have not been forgotten. This report, so clearly and precisely presented, is a fine example of what such a document can be in building up the corporate spirit of a large institution.

New Zealand Earthquakes during October 1948

Nine strong distant earthquakes were registered during October 1948 by the New Zealand seismographs situated at Auckland, Arapuni, Christchurch, Kaimati, New Plymouth, Tuai and Wellington, according to the report from the Dominion Observatory, Wellington. In addition, eighteen earthquakes and tremors were felt by people in New Zealand during the month. The greatest of these had instrumental strength 4½ and was felt at Dunedin and Monowai on October 9. The next most intense had instrumental strength 4¼, and these were felt on October 16 at Otaki and Wanganui, and on October 29 at Hanmer Springs.

Editorial Board of *Chymia*

The University of Pennsylvania Press has announced the appointment of Henry M. Leicester, professor of biochemistry, College of Physicians and Surgeons in San Francisco, as editor-in-chief of *Chymia : Annual Studies in the History of Chemistry*. Dr. Leicester, who succeeds the late Tenney L. Davis as editor, is chairman of the History of Chemistry Division, American Chemical Society, and associate editor of the *Journal of Chemical Education*. Prof. John Read, professor of chemistry and director of the Chemistry Research Laboratory, University of St. Andrews, is the new associate editor of *Chymia*. Other members of the editorial board are : Claude K. Deischer, Rudolf Hirsch, Herbert S. Klickstein and Eva V. Armstrong.

University of London : Appointments

The following announcements of appointments have recently been issued : Prof. H. C. Darby has accepted an invitation to the University chair of geography tenable at University College, and Mr. W. O. Lester Smith to the University chair of sociology of education tenable at the Institute of Education, both as from October 1, 1949. Dr. P. E. Vernon has been appointed to the University chair of educational psychology tenable at the Institute of Education, as from October 1, 1949. Appointments to readerships: Dr. E. T. Eady to the University readership in physical climatology tenable at the Imperial College of Science and Technology, as from October 1, 1949; Dr. A. J. Marshall to the University readership in zoology and comparative anatomy tenable at St. Bartholomew's Hospital Medical College, as from October 1, 1949; Mr. N. H. Martin to the University readership in chemical pathology tenable at St. George's Hospital Medical School, as from April 1, 1949; Dr. J. R. Raeburn to the University readership in agricultural economics tenable at the London School of Economics, as from October 1, 1949; Dr. J. W. Smith to the University readership in chemistry tenable at Bedford College, as from October 1, 1949.

University of Bristol: Appointments

DR. H. S. HELLER, reader and head of the Department of Pharmacology and Practical Pharmacy in the University of Bristol, has been appointed the first occupant of the new chair of pharmacology in the University. Dr. H. A. Heilbronn, reader in pure mathematics in the University, has been appointed to succeed Prof. H. R. Hassé as Henry Overton Wills professor of mathematics. Both these appointments take effect in the session 1949–50.

Announcements

THE Stamp Memorial Lecture will be given at the Senate House, University of London, by Prof. A. C. Pigou, emeritus professor of political economy, University of Cambridge, on May 13 at 5.30 p.m.; he will speak on "Wage Statistics and Wage Policy". Admission is free, without ticket.

THE Silvanus Thompson Memorial Lecture for 1949 of the British Institute of Radiology will be delivered by Dr. F. G. Spear, of the Strangeways Research Laboratory, Cambridge, at the Institute on April 28; he will speak on "The National Radium Commission in Retrospect".

THE thirty-seventh Wilbur Wright Memorial Lecture of the Royal Aeronautical Society will be given by Dr. Hugh Dryden, director of aeronautical research to the National Advisory Committee for Aeronautics, at the Royal Institution, London, on April 28 at 6 p.m.; Dr. Dryden will speak on "The Aeronautical Research Scene—Goals, Methods and Accomplishments".

IN connexion with the series of lectures on the "Development of Taxonomy" given at the rooms of the Linnean Society during the past winter, there will be a demonstration at the Herbarium, Royal Botanic Gardens, Kew, on May 7 at 2.30–5 p.m. The demonstration, which has been arranged by the Linnean Society and Systematics Association, will illustrate the history and methods of botanical taxonomy from 1753 to the present day, and is primarily intended for advanced university students and teachers.

DR. T. W. PARKER has recently been appointed deputy director of building research in the Department of Scientific and Industrial Research. Dr. Parker, who was educated at the University of Durham, joined the staff of the Building Research Station in 1930. His research work has been mainly concerned with building materials and their use in structures. For some years he was also responsible for the Station's programme of work at the Fire Testing Station, Elstree, before this was taken over by the Fire Research Organisation of the Department.

THE Challenger Society is prepared to consider applications for small grants in aid of research in marine biology or oceanography at a recognized laboratory during the year June 1949–June 1950. Applications, accompanied by details of the proposed research, should reach the honorary secretary, Mr. N. B. Marshall, British Museum (Natural History), London, S.W.7, before the end of May.

AN award is to be made of the studentship in experimental and mathematical aeronautics research established in memory of Edward Teshmaker Busk, who in 1914 lost his life while flying an experimental aeroplane. The studentship, which is worth £165 and tenable for one year at the University of Cambridge, is open to any British man or woman less than twenty-five years of age. Full details may be obtained from the Professor of Aeronautical Engineering, Engineering Laboratory, Cambridge.

THE Medical Research Council is offering the following travelling fellowships for the academic year 1949–50: Rockefeller medical fellowships for postgraduates resident in Great Britain to work in the United States or elsewhere; Dorothy Temple Cross research fellowships in tuberculosis for British subjects to work elsewhere than in Great Britain. Both fellowships are worth £650 per year and there are travelling allowances and a £250 marriage allowance. Application forms, to be completed by June 1, may be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, London, S.W.1.

AN exhibition of calculating machines and equipment will be held in the Firth Hall, University of Sheffield, during April 29 (2.30–8.0 p.m.) and April 30 (10.0 a.m.–6.0 p.m.). The exhibition will be opened by Prof. D. R. Hartree, Plummer professor of mathematical physics, University of Cambridge, who will speak on "Some Recent Developments in Calculating Machines". Lectures will also be given by Mr. G. B. Hey (Trustee Department, District Bank, Ltd.) on "Applications of Punched Card Machines in Accounting and Scientific Computing", and Dr. E. T. Goodwin (Mathematics Division, National Physical Laboratory) on "Calculating Machines: their Nature and Applications". Admission is free.

THE Coal Tar Research Association, now incorporated under the Companies Act of 1948, has leased premises at Gomersal, near Leeds, for its research station. It is expected that the headquarters of the Association will move from the present address, 9 Harley Street, London, W.1, in June and that the laboratories will be completed later in the year.

THE National Physical Laboratory at Teddington is holding an 'open day' on May 26 from 2.30–6.0 p.m., to which representatives of industrial organisations are being invited. This is an opportunity for members of industry to see the wide range of scientific research and investigational work undertaken at the Laboratory, and a number of tickets is being reserved for postal applications. Accredited representatives of industrial organisations who would like to visit the Laboratory and who are not already in contact with its work are invited to apply to the Director, National Physical Laboratory, Teddington, Middlesex, not later than May 14.

ERRATUM.—In the communication entitled "Shape Factor in Particle-Size Measurement" in *Nature* of April 2, p. 527, line 5 from end, for "K is then the standard deviation" read "K_2 is then the standard deviation . . ."

Optical Properties of Barium Titanate

A PAPER by Kay in the *Acta Crystallographica* for November 1948 has just appeared which traverses ground so close to that which we have been exploring during the past two years that it seems desirable to announce at once a few points which seem to be both new and interesting in our work.

In 1946 one of us (R. W.) observed that 'Barkhausen clicks' occurred when a commercial ceramic titanate condenser (Dubilier) was electrically connected in a suitable circuit. We then, in pursuit of the problem, prepared single barium titanate crystals and examined them in polarized sodium light under various conditions of temperature (−5° to 140° C.) and in electric fields up to about 30,000 volts/cm. The well-known twinning (101 and 011 types) was immediately apparent in our small crystals, and in Fig. 1 is shown a scale model of just one example built up on an actual photograph (× 500). This photograph with its legend is self-explanatory.

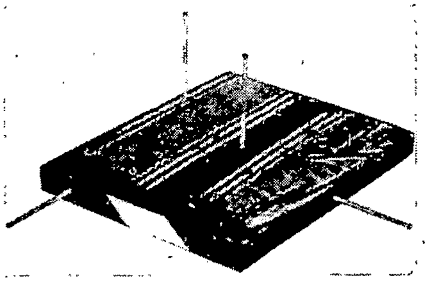

Fig. 1. Scale model of a typical crystal with pins indicating the direction of the optic axis in the twin components

The application, at room temperature, of an electric field of sufficient strength causes the c-axis to turn into the field direction throughout the crystal, a change usually achieved by the growth of small wedge-shaped needles lancing out at 45° from a crystal edge, which, when long enough to extend right across, begin to expand at right angles to their length, finally devouring the whole crystal. This movement may be quite slow, lasting minutes, and is often accompanied by light and dark lines which appear transiently, parallel to the c-axis, when viewed between crossed Nicols near the extinction position. At a twin boundary, these transient lines turn abruptly through 90°, as shown in Fig. 2, which, for reasons we cannot here elaborate, was taken in an alternating field at room temperature. It is thought that this phenomenon may be connected with a change of spontaneous polarization through 180°, these two directions being optically indistinguishable in the steady state.

Fig. 2. Crystal observed near the extinction position in an alternating field of 20 kV./cm. (× 750)

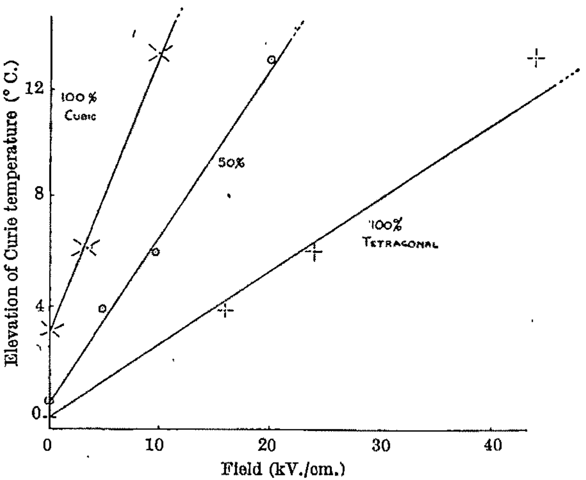

Fig. 3

We have specially examined the behaviour of these small crystals in the neighbourhood of the Curie temperature, the highest value of which was found to be about 121° C. At this temperature the structure changes from tetragonal to cubic; but this transition is inhibited by the application of an electric field, so that with fields approaching breakdown the transition does not occur until as high a temperature as 130° C. is reached. This effect, which has its counterpart in ferromagnetics, is approximately summarized in Fig. 3.

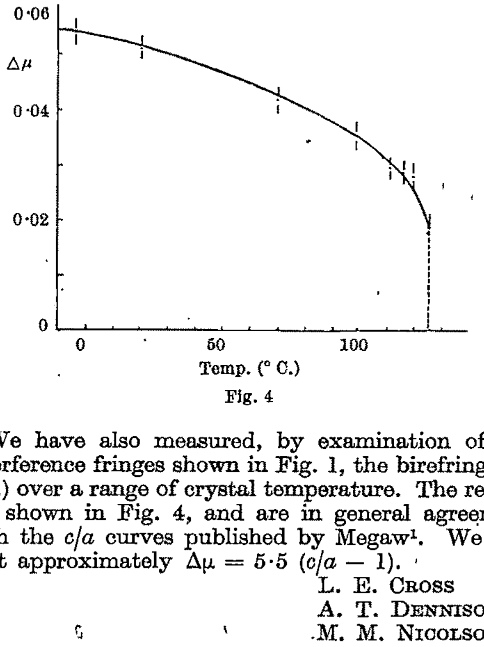

Fig. 4

We have also measured, by examination of the interference fringes shown in Fig. 1, the birefringence ($\Delta\mu$) over a range of crystal temperature. The results are shown in Fig. 4, and are in general agreement with the c/a curves published by Megaw[1]. We find that approximately $\Delta\mu = 5{\cdot}5\,(c/a - 1)$.

Atomic Positions and Optical Properties of Barium Titanate

In view of recent discussion[1,2] of possible departures of some of the atoms of tetragonal barium titanate from the centrosymmetrical configuration of the unit cell (Ba^{+2} at 0, 0, 0; Ti^{+4} at $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$; O^{-2} at $\frac{1}{2}, \frac{1}{2}, 0$; $\frac{1}{2}, 0, \frac{1}{2}$; and $0, \frac{1}{2}, \frac{1}{2}$), the following may be of interest. Oscillation photographs of an untwinned crystal of nearly square cross-section (12 : 13) have been obtained, and reflexions of the type $h,0,0$, $0,0,l$, examined. No intensity differences between these pairs of reflexions have been observed by eye, and from this it is concluded (using F values obtained from the International Tables) that there is no simple shift of the Ti^{4+} ion parallel to the c-axis by more than 0·05 A. or of the O^{2-} ion at $\frac{1}{2}, \frac{1}{2}, 0$ by more than 0·13 A. from the above positions.

Since movements of this magnitude cannot account for the observed value[3] of the dipole moment of the unit cell, this (if its value is confirmed) must result in the main from an effective displacement of outer electrons only, arising from some system of partly polar bonds such as has previously been suggested[1]. We may add here that oscillation photographs of crystals of the hexagonal modification of barium titanate have also been obtained which show that this has a slightly more open structure than the tetragonal form, and that the lengths of the Ba—O and Ti—O bonds are again different in different directions.

It is hoped shortly to establish the exact parameters of the tetragonal crystal to a higher degree of accuracy with the aid of Weissenberg photographs.

The uniaxial character and orientation of twins in barium titanate have been confirmed by optical observation between crossed Nicols, using a quartz wedge.

Observations on thin plate-like crystals having their tetragonal c or optic axis in the plane of the plate have shown that the usual method of twinning often results in a pair of boundaries having a separation of approximately 10^{-4} cm. Such pairs or 'double boundaries' may terminate within the crystal by oblique junction, or may extend right across it with constant separation. The enclosed material has its optic axis perpendicular to that of the adjacent twins and also in the plane of the plate, so that an isolated 'double boundary' consists of a thin lamella of material having its polar direction perpendicular to the rest of the crystal (Fig. 1). The double-boundary separation appears to be independent of the crystal thickness and shape, and to have a minimum value of approximately 2×10^{-4} cm. This twin formation is one which will relieve internal shear stresses in a crystal and will result in minimum change in external shape.

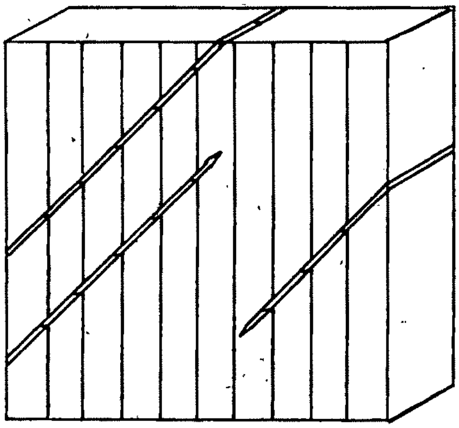

Fig. 1. Twinning in $BaTiO_3$ crystals; shading shows direction of c axis

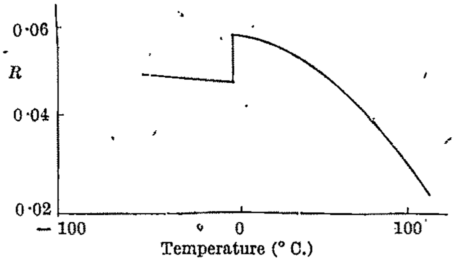

Fig. 2. Birefringence curve for $BaTiO_3$

The birefringence (R) has been measured for a large number of crystals by a rapid method, using white light. The absolute value varied from 0·50 to 0·59 at 30° C. The variation of (R) in the temperature range − 50° to 120° C. was also measured for a few crystals by a compensation method using filtered radiation. Fig. 2 shows the relation between the birefringence (R) and temperature (θ). The curve between − 5° C. and $\sim$ 120° C. fits the equation $(K - R) = \alpha(T - \theta)^2$, where $K = 0{\cdot}62$ is the maximum value of R at $\sim -$ 5° C. and R changes discontinuously; α is a proportionality constant which depends on the transition temperature. The variation of $c - a$, the difference in axial lengths of the unit cell, is of the same form, so that there is a simple linear relation between $(c - a)$ and R. From the value of R we may therefore tentatively calculate the axial ratio in any part of the crystal under other conditions.

There is a difference in the birefringent colours of the material enclosed in a double boundary and the adjacent twins. This is possibly due to the fact that c/a is less in these areas, this reduction being the result of the mechanical and electrical stresses around a double boundary, which may also determine its separation.

The orientation of c in the double boundaries is confirmed by the application of an electric field. Then their length and separation increases or decreases as the field is parallel or perpendicular to their c direction. Another transition occurs at − 5° C. The optical behaviour suggests that the tetragonal unit-cell shears in the (001) plane, the new axes being approximately parallel to the [110], [110] and [001] directions of the original cell, the symmetry being orthorhombic. Assuming the relation between $(c - a)$ and R applies approximately in this region, $(c - a)/a$ is reduced by approximately 15 per cent at the transition at − 5° C. and increases slightly at still lower temperatures. Further investigations by X-ray methods are to be undertaken.

The application of electric fields of approximately 2×10^4 volts/cm. to twinned crystals has resulted in complete orientation of the tetragonal axis along the field direction (that is, electric saturation). The field across the crystal itself is very much less, because of the high dielectric constant of barium titanate, together with the air-gap between the crystal and electrodes. This gap is an essential condition, since the crystal expands along the field axis in the process, c being greater than a.

Note added on January 26, 1949. The transition at $\sim -$ 10° C. has been studied by X-ray methods, a shear of 14′ in the $a-c$ plane being observed at $-16°$ C. ($\beta = 89° 46'$). Associated with this change there is an expansion of the a parameter and a slight contraction of c, such that these two parameters become equal, and the polar direction turns through 45° into the [011] or [101] direction. A further transition occurs near $-70°$ C., below which temperature the symmetry appears to be rhombohedral with the polar axis in the former [111] direction.

A New Application of White-Light Superposition Fringes

White-light superposition fringes have found a number of applications in the past. They are of two kinds—fringes of equal inclination and of equal thickness. Extensive use of the former has been made, first in Brewster fringes, later in the Jamin interferometer; then in 1898 Fabry and Buisson first used multiple-beams, ultimately adopting the fringes for their classical evaluation of the metre. A more recent application has been made by Sears and Barrell in determining the refractive index of air.

Comparable use of white-light superposition fringes of equal *thickness* has not, however, been made; apart from a few experiments described by Fabry in his book "Les Applications des Interférences Lumineuses" (1924), there is little to record. It is the purpose of this note to describe a simple application which reveals qualitative information with high precision.

It has already been demonstrated by interferometry that many varieties of muscovite mica cleave surprisingly true over large areas. A randomly selected sheet of muscovite was silvered on both sides. It was then cut into two with scissors and the two pieces held superposed on each other. The combination was placed in the parallel beam of a standard Fizeau fringe set-up, but with white light. Thus an image of a 'Pointolite' is thrown on to an aperture which is at the principal focus of a lens, and the emergent parallel beam of white light directed at normal incidence on to the mica combination. A lens follows the mica, and the eye is placed at the lens focus. The appearance is striking. Following recognized principles, it is clear that localized white-light superposition fringes of equal thickness will form. If the two pieces of mica consisted of pieces of strictly constant thickness, then the field of view would consist merely of a uniform tint of illumination. But, in fact, there are cleavage steps on mica surfaces and, as is already known, these usually occur in simple multiples of the crystal lattice spacing (20 A.) and may, in fact, be only a single lattice high. It is clear that the superposition principle leads effectively to the production of thin-film interference over path-differences representing the heights of the cleavage steps. The result is that the field of view shows brilliantly coloured areas, each of uniform tint, each being delineated by the boundary of cleavage lines. Thus, in a highly sensitive (but only qualitative) manner, the structure of the mica sheet is revealed. For not only do height changes lead to colour variations, but also inclusions and variations of refractive index have a like effect.

It remains to ask whether this rather restricted new technique has any advantages over the monochromatic multiple-beam method already in use for thin films. The answer is, yes. In two respects the new method is a decided improvement on the old. First, when using monochromatic light, the very sharpness of the fringe distribution is such that cleavage steps may easily be missed if the transmission region corresponds to a thickness well off the intensity maximum; secondly, it can be readily demonstrated by simple calculation that the fringe-width in the combination system is $1/\sqrt{2}$ that in the single system. There is, therefore, a 40 per cent increase in sensitivity.

It is to be emphasized that the interference colours are determined primarily by the individual step-heights and not by the thickness of the mica sheet. With very strict collimation, it should certainly be possible to apply the technique to thick slabs. This being so, equal slabs of optical material can be exactly matched and accurately surfaced, for example, with the dividing plate and compensating plate in a Michelson interferometer, or the plates for a reflexion echelon, etc. Other applications, with both thin and thick interference gaps, come readily to mind.

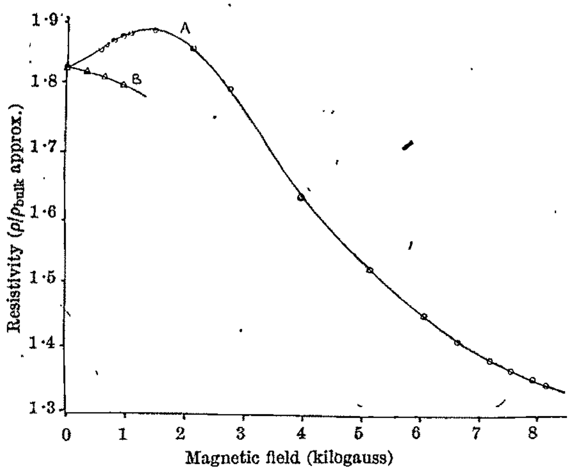
Influence of a Magnetic Field on the Size-Variation of Electrical Conductivity

Miss I. Stone[1], in 1898, appears to have been one of the first to make a study of the anomalous increase in specific resistivity of very thin metal films as compared with specimens in bulk, although the phenomenon was already known. Films of silver as thin as $\sim 1 \times 10^{-6}$ cm. deposited by the 'Rochelle salt process' were used by her. Longden[2] extended this work to evaporated films of platinum, and since that time a considerable amount of work has been carried out on such thin films (for example, bibliography in ref. 3). J. J. Thomson[4] first proposed that the physical limitation of conductor size would produce a shortening of the electron mean free path, with a consequent reduction of effective conductivity, and derived a theoretical expression based on an assumption of a constant mean free path in the bulk metal.

More recently, the accessibility of very low temperatures has enabled the effect to be observed in specimens of considerably larger size ($\sim$ 10–100 μ), with the resulting elimination of a number of subsidiary effects which arise in very thin films. In particular, Andrew[5] has studied wires of pure mercury, and wires and foils of pure tin in the region 1–4° K. One difficulty, emphasized by Andrew, in the interpretation of the data is that of relating the measured conductivity to that of an equivalent bulk sample, since strain and impurity—both productive of high residual resistance at low temperatures—may be expected to play a significant part in finer specimens.

Modern theories of metallic conduction as applied to the phenomenon[6] require an assumption of the degree of 'freeness' of the conduction electrons. It



Variation of resistance with magnetic field: *A*, transverse field; *B*, longitudinal field. (Temp. 4·2° K.)

was therefore considered that an investigation on fine specimens of pure sodium would be worth while, since earlier work on the alkali metals[7] had suggested strongly that the conduction electrons in sodium are almost ideally free. It was also intended in this work to examine the effect in relation to temperature from 20° K. to ~ 4° K., to deduce any variation of the surface reflexion coefficient. Results in this field will be published later; but an interesting effect has been observed when a magnetic field is applied.

The accompanying graph shows the observed variation of electrical resistance in a specimen 30 μ diameter under the application of transverse and longitudinal fields. It is immediately obvious that the effect is essentially of a different character from the customary increase of resistance in a magnetic field (magneto-resistance effect). The remarkable reduction of resistance may be understood if one observes that in a field of ~ 4,000 gauss the conduction electrons in sodium will describe classical orbits of diameter 30 μ. Thus, for example, an electron, having been scattered from one surface of the metal, may have its path so curved by the magnetic field as to avoid subsequent collision with the opposite wall of the specimen and thus have an increased effective path-length. Ultimately, for a sufficiently strong longitudinal field, one would expect that scattering by the walls would become insignificant in comparison with that in the body of the metal. In this case the resistivity should approach a lower limit, namely, that of the metal in bulk. In a transverse field, a similar decrease should occur, although the limiting resistivity will then be greater than that of the bulk material since those electrons travelling more or less parallel to the field will still collide with the walls. With a transverse field, elementary considerations show also that some electrons, dependent on their direction of motion, will suffer an initial diminution of free path which may predominate, although ultimately all free paths should increase. This effect is obvious in the graph, the resistance reaching a maximum around 1,500 gauss for this specimen. On the other hand, one would only expect a progressive increase of free path with a longitudinal field, the electrons pursuing spiral paths around the lines of force. The experimental data confirm this assumption. Measurements on specimens of different sizes under varying fields should provide a knowledge of mean free path and surface scattering coefficient individually: publication of full experimental data and theoretical discussion will follow later.

In conclusion, one may note that this phenomenon is to be distinguished from the diminution of the magneto-resistance effect in very thin films as observed by Patterson[8] and explained by Thomson[4]. In that case, the increased electron-scatter in bulk metal arising from the action of a magnetic field loses its effect as the electron free path becomes curtailed by the physical limits of the specimen.

Fermi Resonance in Benzene

THE existence of a strong doublet rather than a singlet line in the Raman spectrum of carbon monoxide was explained by Fermi[1] on the theory that when in multi-atomic molecules the frequencies of two independent vibrations are commensurable or nearly so, the vibrations perturb each other, resulting in a mutual repulsion of the two levels and a mixing of eigenfunctions, provided the two vibrations belong to the same symmetry species. Such Fermi resonance is found to occur frequently in many polyatomic molecules, and enables one to explain some characteristic features of Raman and infra-red spectra. For example, it is well known that the Raman spectrum of benzene exhibits two strong lines due to frequencies 1606 cm.$^{-1}$ and 1584 cm.$^{-1}$, whereas only one at 1596 cm.$^{-1}$ is to be expected corresponding to the e_g^+ vibration. The occurrence of this doublet was shown by Wilson[2] to be due to Fermi resonance between 1596 cm.$^{-1}$, which is a pure e_g^+ frequency, and a binary combination 606 cm.$^{-1}$ + 992 cm.$^{-1}$ = 1598 cm.$^{-1}$, the total eigenfunction of which has again the e_g^+ symmetry.

In the course of an analysis of the near ultra-violet emission bands of benzene[3], we have discovered an extended series of such Fermi doublets. The main characteristics of the emission spectrum are represented by progressions of totally symmetric vibrations superposed over one of the e_g^+ vibrations in either state, which circumstance is essential to permit the otherwise forbidden transition. The extended series of Fermi doublets arises in the superposition of one to four quanta of 992 frequency on each of the fundamental doublets, each of which again is loaded with one to four quanta of 160, the difference frequency. The observed data are in agreement with theoretical calculations based on first-order perturbation brought about by the cubic anharmonicity factor in the potential energy function of the molecule.

A detailed account has been submitted for publication elsewhere.

Low-Level Atmospheric Ducts

In a recent communication in *Nature*[1], McPetrie and Starnecki have directed attention to the presence of atmospheric ducts at or close to the sea surface. The presence of low atmospheric ducts when the air at 100 ft. above sea-level was colder than the sea was found difficult to explain, and it was noted that such ducts were frequently associated with high wind speeds.

In a recent paper[2] of limited circulation dealing with observations in Cardigan Bay, I have shown that the mean specific humidity, s, of the air in the layer between 200 and 2,000 ft. above the sea, after an uninterrupted sea track, is related to the saturation specific humidities at the sea surface temperatures during the previous 48 hours history of the air by an expression of the form

$$s = 0\cdot34\ (s_1 + s_2),$$

where s_1 is the saturation specific humidity at the sea surface temperature at the place of observation, and s_2 that for the sea surface temperature at the place where the air was 48 hours before. Thus the lower the value of s_2 (s_1 varies only slowly with time and is sensibly constant over a period of days at a particular place in Cardigan Bay) the lower the value of s, and hence the greater the value of the humidity lapse in the lowest layers of the air. In the same paper[2], it is suggested that much the greater part of this humidity lapse frequently occurs in the lowest few feet of the air. If the air under examination comes from an area where the sea surface temperatures are much lower than in Cardigan Bay, then the stronger the wind the colder the sea surface temperature at the place the air was 48 hours before, and the greater the value of the humidity lapse in the Cardigan Bay area. The occurrence of low-level radio ducts in conditions of high winds when the air temperature is substantially less than the sea surface temperature can therefore be explained on this basis alone. The occurrence of ducts when the air temperature at 100 ft. was substantially above the sea temperature can almost certainly be explained by the presence of air which had recently come from the warmer and drier land, with the consequent presence of both temperature inversion and humidity lapse in the lowest layers, leading to even stronger ducts than those considered above. It is extremely unlikely that temperature inversions of such magnitude accompanied by a marked humidity lapse could occur over the sea, except in the neighbourhood of a warmer land mass.

I am indebted to the Director of the Meteorological Office for permission to submit this note.

[1] *Nature*, **162**, 818 (1948).

[2] Jones, R. F., "Temperature and Humidity Structure of Lowest Layers of the Air over the Sea", Air Ministry, J.M.R.P. No. 92 (1947).

We are grateful to Mr. Jones for outlining his suggestion as to a possible method for the formation of the low-level atmospheric ducts in Cardigan Bay which we postulate from our radio field-strength measurements. According to current radio-meteorological theory, ducts should not occur during turbulent conditions. It surprised us, therefore, to find from the radio measurements that in the winter high field-strengths, which suggest to us the presence of low-level ducts, could occur even during windy weather. Mr. Jones's hypothesis gives a very satisfactory quantitative explanation of a method by which ducts might be formed during such periods of high wind velocity. High field-strengths during winter, however, appeared to depend more on the fact that the temperature of the air was appreciably lower than that of the sea, rather than on the presence or absence of wind. The main difference between windy and still conditions was not in the amplitude of the received signal but in its stability, remarkably little fading ever being found during windy periods.

Sverdrup, in his book "Oceanography for Meteorologists", arrives at the conclusion that the greatest evaporation occurs when cold air flows over warm water; as in middle and higher latitudes in winter the sea surface is mostly warmer than the air, evaporation should be a maximum in winter and not summer, as generally supposed. Sverdrup's results, while only qualitative, seem to us to account satisfactorily for the possibility of ducts occurring during still air conditions in winter. Sverdrup also concludes that the evaporation should be increased at higher wind velocities because of the presence of spray—a hypothesis which we tentatively suggested in our note to explain the presence of ducts during windy conditions.

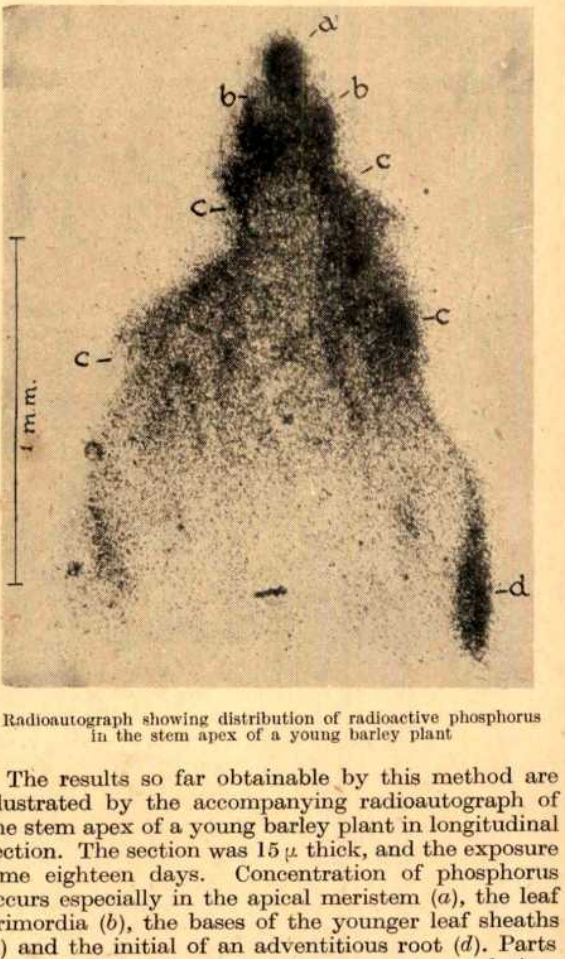
Preparation of Radioautographs to Show the Distribution of Phosphorus-32 in Plant Tissues

Pelc[1] has developed a radioautographic technique to show in microscopic detail the accumulation of iodine-131 in the thyroid gland. A thin 'stripping' photographic emulsion is floated on to the tissue sections mounted on a glass slide. The precision with which the tracer can be located within the tissue depends not only on the thinness of the section and the emulsion but also on the closeness of contact between them. In applying this method to the study of the distribution of phosphorus in plant tissues the following complications arise: (1) a considerable diffusion of phosphorus occurs in the fixatives normally used; (2) the time required to prepare sections by standard plant histological methods is so long that much of the tracer decays before the radioautograph can be exposed.

We have found that these difficulties can be largely overcome by employing a 'freezing substitution' technique which one of us (F. K. S.) is developing for other purposes, and following this by a rapid imbedding method. The time required for preparing sections of material such as cereal root tips has thereby been reduced to twenty-four hours.

The tissue is frozen in *iso*pentane chilled to about − 170° C. and then transferred to absolute alcohol saturated with basic lead acetate, which is maintained at − 70° C. in a jacket of 'dry ice' alcohol. The ice in the tissue *dissolves* slowly in the cold alcohol and the phosphate is precipitated *in situ* as the lead salt. The material thus fixed and largely dehydrated is then imbedded in paraffin wax using tertiary butyl alcohol[2] as a solvent and sectioned in the normal way. Radioautographs are then made by the method of Pelc[1].

Since it is necessary to keep the concentration of tracer below a level at which radiation damage is likely to occur[3], thin fine-grain emulsions such as that described by Berriman[4] and Stevens[5] are usually too slow. A faster Kodak experimental radioautographic stripping emulsion has therefore been used. On account of its thickness, this emulsion gives poorer resolution, but points of accumulation of tracer approximately 15 μ apart can be distinguished one from another.



Radioautograph showing distribution of radioactive phosphorus in the stem apex of a young barley plant

The results so far obtainable by this method are illustrated by the accompanying radioautograph of the stem apex of a young barley plant in longitudinal section. The section was 15 μ thick, and the exposure time eighteen days. Concentration of phosphorus occurs especially in the apical meristem (*a*), the leaf primordia (*b*), the bases of the younger leaf sheaths (*c*) and the initial of an adventitious root (*d*). Parts of the vascular tissue also show some accumulation. For the sake of clarity in reproduction, the radioautograph was removed from the section before it was photographed. The most convenient method for locating the site of accumulation of the tracer is, however, to examine the radioautograph and section in contact. Since it is difficult to stain tissues in contact with emulsions, the phase-contrast microscope is useful for this purpose.

Fuller details of the histological and radioautographic techniques will be published elsewhere.

We are indebted to the Agricultural Research Council for providing a grant in aid of the tracer work the Department of Agriculture; we wish also to thank Dr. S. R. Pelc of the Medical Research Council Radiotherapeutic Unit for much valuable advice, and Dr. R. H. Herz and the Kodak Research Laboratories for the gift of the photographic emulsions.

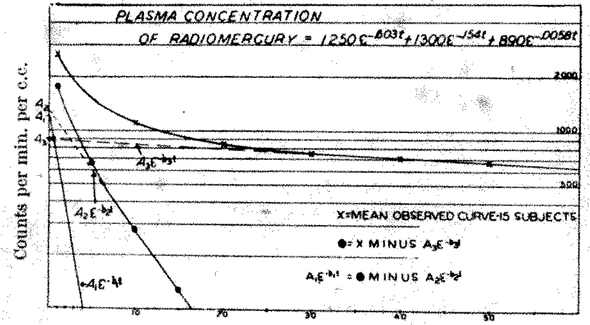
Regression of a Radioactive Mercurial Diuretic from the Plasma of Man

DURING the study of the mechanism of chronic congestive heart failure and other œdematous states, it became more evident that there is need for a better understanding of the pharmacodynamics of mercurial diuretics. Investigations have been carried out with the use of radioactive mercury incorporated in a mercurial diuretic, 'Mercuhydrin' (sodium salt of methoxyoximercuripropylsuccinylurea with theophylline, prepared in this laboratory by Messrs. H. Krahnke, E. Sprengler and D. Kaestner through the courtesy of Dr. H. L. Daiell of Lakeside Laboratories, Milwaukee, Wisconsin, with the use of mercury-203–205 from the A.E.C. Oak Ridge Operations), in order to observe for a period of 100–180 min. the concentration-time course of the isotope in the plasma of man after intravenous injection.

Fifteen subjects were studied. 2 c.c. of labelled mercurial diuretic was injected into the antecubital vein of one arm of the subjects over a period of about 20 sec., and blood samples were drawn rapidly from the antecubital vein of the contralateral side. The interval between collection of blood samples was 4–8 sec. for the first two or three minutes, thereafter increasing as the experiment progressed. After the blood was centrifuged, 0·3 c.c. of serum was placed upon a filter paper disk, allowed to dry and cemented to a metal disk for counting. Measurements of radioactivity were recorded as counts per minute per cubic centimetre of fluid, and were corrected to values corresponding to an injected activity of 10,000,000 counts per minute of radioactive mercury.

The regression-curves observed in all subjects were similar. The accompanying graph, the composite regression curve of all fifteen subjects, is analysed graphically into three exponential rates of regression.

The regression-rates contributing to the concentration-time course of radioactive mercury in the plasma of man are not simple phenomena; rather they are probably the expression of many simultaneously occurring physico-chemical processes. The most rapid regression-rate is brought about largely by mechanical mixing of the tracer in the plasma along with some extremely rapidly occurring biological events. The second regression-rate probably expresses the filling of the potential mercury spaces and the activation of 'potential turnover patterns' for mercury, including diffusion and chemical reactions, which did not actually exist until a relatively



The mean observed plasma concentration-time curve of radiomercury for 15 subjects who received 'Mercuhydrin' intravenously. This curve is analysed graphically into its three exponential regression-rates. The sum of the three individual daughter curves at any time represents the total concentration of radiomercury in the plasma at that time expressed by the general equation,

$$C_p = A_1\varepsilon^{-b_1t} + A_2\varepsilon^{-b_2t} + A_3\varepsilon^{-b_3t}$$

large quantity (78 mgm.) of the element was administered. The third regression-rate is most likely primarily a reflexion of the elimination of the mercury from the body, principally urinary. This is supported by the fact that urinary excretion of radiomercury accounts for practically all this element lost from the plasma after 40 min. or so from the time of injection.

This analysis of the regression of mercury from the plasma of man is undoubtedly an over-simplification of multiple complex phenomena; but it serves as a basis for an understanding of other data dependent upon the concentration of mercury in the plasma. A more detailed discussion of the concentration-time course of radioactive mercury incorporated into a mercurial diuretic will appear elsewhere.

Significance of the Enzymic Degradation of Cozymase in Living Organisms

Reason for the existence of a very potent enzyme system degrading cozymase in brain[1] and in certain other cells and tissues[2] has been obscure, as intact cozymase is so important to their normal functioning. The rate of breakdown by ground brain is of the order of 1 μmol./mgm. dry weight/hr.[1], whereas the rate of respiration by the intact tissue is about 0·5 μmol./mgm. dry weight/hr. Brain preparations split the cozymase molecule between the pyridine-N and ribose[1]. The results in Table 1 now show that the degrading enzyme can serve cellular economy in the following ways: (1) By decreasing the quantity of specifically the oxidized form of either coenzymes I or II in coenzyme-dihydrocoenzyme mixtures, their oxidation-reduction potentials can be expected to be lowered, and we have found this to be the case experimentally. (2) This can be expected to affect secondarily the many enzymes sensitive to changes in E_H. (3) The degrading enzyme will compete with dehydrogenases for the oxidized forms of the coenzymes, and in mixtures of dehydrogenases favour the action of those of greatest affinity for the coenzymes. (4) Equilibria at certain dehydrogenases can be expected to be modified by the additional presence of an enzyme which removes one component from the system of four which are typically involved. Thus the formation of β-hydroxybutyric acid would be expected to be favoured in the β-hydroxybutyric–acetoacetate system.

Table 1. Substrate specificity of the enzyme-degrading cozymase

Potential substrate (5×10^{-4} *M*)	Relative rate of degradation
Cozymase	100
Dihydrocozymase	< 0·5
Coenzyme II	65–80
Dihydrocoenzyme II	< 0·5
Cozymase with Dihydrocoenzyme II	90–100

These effects can be expected to influence the course of major reactions in most living systems in which the cozymase-degrading enzyme exists. In agreement with this, considerable changes in carbohydrate metabolism of brain slices have been found[3] to follow inhibition of this reaction by nicotinamide[4], nicotine, 5(4)-3′-pyridylglyoxaline[3] or phenosafranine[5]. The disturbances have included increases (up to ten-fold) in the rates of aerobic or anaerobic glycolysis. Phenosafranine was previously known to inhibit the Pasteur effect in mammalian tissues including brain[5], and some actions of nicotine[6] can be interpreted similarly. The specificity of action of these inhibitors is discussed elsewhere[3]. This evidence for the action of the degrading enzyme in normal tissues implies the existence also of active processes for resynthesis of the coenzymes[7]. The evidence of Judah and Williams-Ashman[8], that linkage between oxidation and phosphorylation in tissue homogenates is inhibited by concentrations of phenosafranine comparable with those of the present experiments, suggests that the degrading enzyme functions in aerobic phosphorylation. Its inhibition, leaving more inorganic phosphate and cozymase available for glycolysis than would otherwise be the case, would thus disturb the Pasteur effect.

Effects of the enzyme from the central nervous system on redox potentials can be very easily demonstrated by experiments of the type illustrated in Table 2. In this, dihydrocozymase to 10^{-4} *M* was added in Thunberg tubes to solutions containing the dyes of Table 2 in phosphate, *p*H 6·5, with a 1/30 dilution of a heart extract[9]; half the tubes contained a preparation of the cozymase-degrading enzyme from beef spinal cord (1·2 mgm. dry weight/tube, capable of degrading 3 μmol. cozymase/hr.). The enzyme had no effect on reduction of the positive methylene blue, but caused much greater reduction of the two negative dyes.

Table 2. Effects of cozymase-degrading enzyme on the degree of reduction of dyes by dihydrocozymase

Dyes	Percentage reduced	
	without enzyme	with enzyme
Methylene blue	>97	>97
Neutral red	20	86
Benzyl viologen	< 3	8

It is also interesting to observe that an enzyme which inactivates dihydrocozymase at a greater speed than cozymase has been observed in certain tissues, including intestinal mucosa[10]. This enzyme can be expected, by arguments similar to those advanced above, to raise redox potential. The coenzyme-degrading system in mammalian nervous tissue is associated with structures insoluble in physiological salt solutions[11] and can be expected to cause local differences in the concentrations of the coenzymes. It will be observed that several other enzymes exist which rapidly degrade other constituents[12] very important in normal cell economy, and that these can similarly be regarded as controlling group potentials[13]. In particular, adenosine triphosphatase shows many analogies with the cozymase-degrading system, and the two are, indeed, likely to have interrelated effects[14]. The possible connexions of these with the specific functions of nervous tissues are discussed elsewhere[15].

*l-nor*Adrenaline in the Suprarenal Medulla

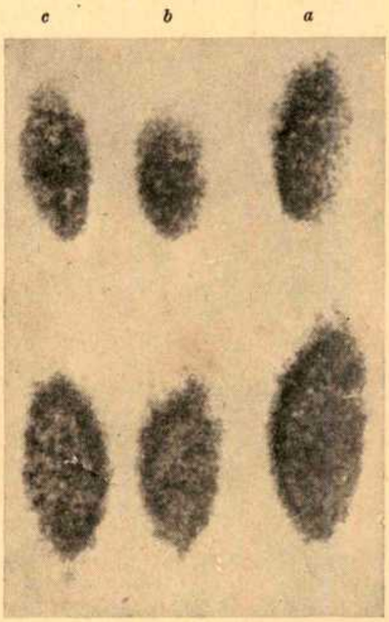
THE demonstration that *nor*adrenaline constitutes the specific neurohormone of adrenergic nerve fibres (sympathin N)[1] has directed attention to the occurrence of this substance in biological material. A recent contribution in this field is the report by Pamela Holton[2] that adrenal medullary tumours contain a high proportion of *nor*adrenaline. Normal suprarenal glands also contain *nor*adrenaline, as shown by Holtz[3]. The present report confirms these findings with the use of different techniques.

Suprarenal glands from cattle were extracted with 5 per cent trichloracetic acid and the acid removed with ether. The extracts were tested for the presence of *nor*adrenaline biologically by the blood pressure of the cat before and after 933 *F* and by using paper chromatography[4]. Quantitative determinations of *nor*adrenaline and adrenaline were made according to the method of Euler and Hamberg[5]. The latter method depends on the different *p*H-optima for the formation of adrenochrome and *nor*adrenochrome with iodine. At *p*H 4 and an oxidation time of 1½ min., the formation of adrenochrome is complete, whereas only approximately 7 per cent of the *nor*adrenaline is oxidized. At *p*H 6 an oxidation time of 3 min. gives the sum of adrenochrome and *nor*adrenochrome.

Extract	*nor*Adrenaline–HCl (μgm./mgm. fresh tissue)	Adrenaline–HCl (μgm./mgm. fresh tissue)
1. 49 gm. whole glands	0·68	1·80
2. 70 gm. ,, ,,	0·70	1·98
3. 500 gm. ,, ,,	0·48	2·16
4. 6·0 gm. medulla	2·68	11·3

The colorimetric method would not differentiate between *dl*- and *l-nor*adrenaline. The activity was therefore tested on the blood pressure of the cat and compared with adrenaline and *l-nor*adrenaline. Extract 2 was equivalent to 2·0 μgm. *l-nor*adrenaline per mgm., or 3·2 μgm. adrenaline per mgm. (ratio 1·6 : 1). The figures found colorimetrically would give $\frac{1\cdot98}{1\cdot6} + 0\cdot70 = 1\cdot94$ μgm. *l-nor*adrenaline activity on the blood pressure per mgm., which compares well with that actually found. After treatment of the cat with 933 *F*, which reversed the action of adrenaline but not that of *nor*adrenaline, a mixture of 2 μgm. adrenaline and 0·7 μgm. *l-nor*adrenaline gave the same picture as 1 mgm. extract and differed markedly from the effect of 3·2 μgm. adrenaline. Extracts 3 and 4 yielded similar results.

Paper chromatography with *n*-butanol saturated with *N* hydrochloric acid as solvent gave a close correspondence between the migration of a suprarenal gland extract purified by adsorption to alumina and a mixture of *nor*adrenaline and adrenaline (see accompanying illustration).



Paper chromatogram with acidulated *n*-butanol as solvent. (*c*) Mixture of *nor*adrenaline and adrenaline in proportion 1 + 2. (*b*) Extract of suprarenal gland purified by adsorption on alumina. (*a*) Mixture of *b* and *c*. •Upper set of spots represents *nor*adrenaline, lower set adrenaline

The presence of a sympathomimetic compound in suprarenal extracts with stronger blood-pressure action than adrenaline, such as *l-nor*adrenaline, is also indicated by the earlier results of Schild[6].

The present results show that the normal suprarenal gland from cattle contains *l-nor*adrenaline in appreciable amounts, as previously shown for adrenergic nerves. The results support Blaschko's concept of adrenaline formation in the chromaffine cells[7].

Proteolytic Activity in Eggs and Sperms from Sea-Urchins

In studying the influence of water extracts from fertilized *Arbacia lixula* eggs upon unfertilized eggs, J. Runnström found that the jelly coat was attacked by the extract (unpublished). In order to examine this activity, extracts were prepared from fertilized and unfertilized eggs and also from sperm. The material was collected at the Zoological Station, Naples, in the spring of 1948, and the investigations started there and continued in Stockholm.

The material was lyophilized and the extractions carried out in the cold for six hours; afterwards it was dialysed for 24 hours against sea water. The activity was tested on gelatin and the effect measured in Ostwald viscosimeters at 35·5° C. The buffer capacity of gelatin was sufficient to maintain the *p*H during the experiment. The samples were made up of 1·00 ml. extract and 3·00 ml. of 4·0 per cent gelatin (Fisher Sc. granular, containing 0·005 per cent merthiolate), as sterilizing agent.

Extracts from eggs. As shown in Fig. 1, there is some proteolytic activity in the unfertilized egg; but three minutes after fertilization the activity is stronger than in unfertilized eggs. Thus it can be assumed that after fertilization there is liberated in the egg a proteolytic enzyme (or complex of enzymes) taking part in the processes occurring after fertilization; but after a brief time the activity of the enzyme is abolished. The activity exhibited by extracts from unfertilized eggs is perhaps due to activation during the freezing or the extraction.

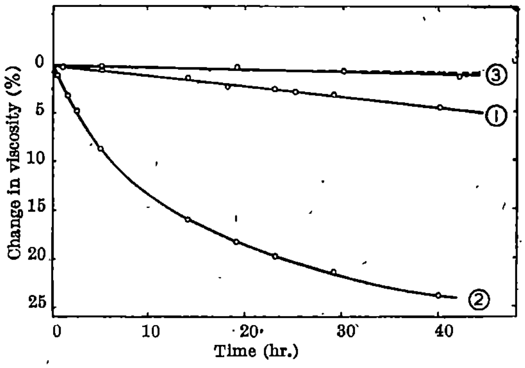

Fig. 1. Activity of egg extracts (*Paracentrotus*). (1) Unfertilized eggs. (2) Three minutes after fertilization. (3) Thirty minutes after fertilization. Control (extract 1 boiled 30 min.): dashed line. Initial concentration of dry matter 1·8 per cent. Temp. 35·5° C. *p*H 6·25

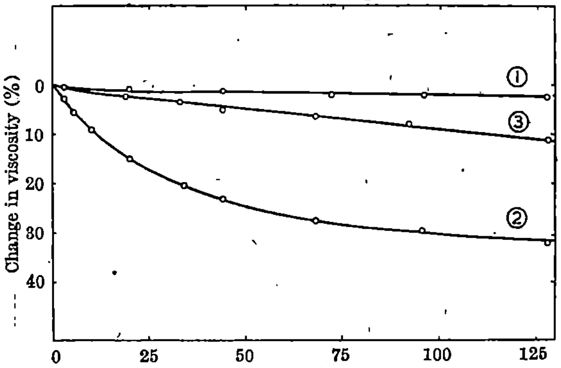

Fig. 2. Activity of sperm extracts. (1) *Arbacia* control (extract boiled 30 min.). (2) *Arbacia* extract. (3) *Paracentrotus* extract. Initial concentration of dry matter 5·0 per cent. Temp. 35·5° C. *p*H 6·45

Extract from sperms. Fig. 2 shows the activity of two different sperm extracts, one from *Arbacia*, another from *Paracentrotus lividus*. The former is more active than the latter. It is not yet established whether this depends upon a lower concentration of the enzyme, or on a lower rate of extraction in the *Paracentrotus* sperm.

A full report of this work will appear elsewhere. I wish to express my gratitude to Prof. J. Runnström for suggesting the subject.

Effect of Humidities and Temperatures on the Size and Number of Oocysts of *Plasmodium gallinaceum* Transmitted by a Mosquito

Mosquitoes need a certain amount of moisture in the atmosphere in which they live. From the investigations of earlier workers[1], we find that changes in the humidity influence the longevity of the insect host and consequently that of the parasite within; low, as well as very high, humidities are detrimental. But if a mosquito is infected with the malaria parasite (*Plasmodium*), the size of the oocysts is not influenced by atmospheric humidity. As to the number of oocysts, according to Gill's work, this is not influenced either. In the work done here, *Aedes ægypti* were fed on chicks infected with *Plasmodium gallinaceum*, and the speed and degree of development of oocysts in the mosquito under various climatic conditions were studied.

Method and technique. In these experiments the mosquito was looked upon solely as the medium in which the parasite grows. Jars containing sulphuric acid and water in various proportions were used to obtain varying degrees of relative humidity. In a preliminary experiment, mosquitoes just fed on a chick were put in celluloid cylinders covered with netting inside the jars. At temperatures of 18° and 25° C., and relative humidities of 50, 60 and 70 per cent, most mosquitoes lived five or more days; this is long enough to allow oocyst development. At either 30 or 90 per cent relative humidity the mosquitoes died in a short period.

In a second series of experiments, a highly infective chick was chosen, and offered to the mosquitoes in their cages. Twenty engorged mosquitoes were then placed in cylinders inside the jars. One jar at each humidity was incubated at 25° C., and another set of three jars in the laboratory at ± 18° C. On the sixth day after the meal the numbers alive were as follows:

	18° C.			25° C.		
Relative humidity	50	60	70	50	60	70
Mosquitoes	12	17	15	13	16	14
Oocysts, mean	10·92	28·76	28·80	11·00	33·25	32·06

These were dissected, the number of oocysts and their size measured in each individual mosquito. The results are shown in the bottom line of the table.

As regards the size of these oocysts, they did not seem to vary much, though those kept at 18° C. were on the average smaller than those at 25° C. Measurements ranged between 15·8 and 17·6 μ at 18° C., and between 18·5 and 20·2 μ at 25° C.

Discussion. Humidity does not affect the speed of development of oocysts (which is affected by temperature); but it clearly affects the number of oocysts which develop, a low humidity being associated with a smaller number of parasites.

One might perhaps think that a low humidity would kill the most heavily infected mosquitoes, because the plasmodial infections might have injured them. But this explanation is ruled out, for the figures do *not* demonstrate a particularly high mortality at the lowest humidity which I used (50 per cent). One is left to suppose that at the lower humidity the increased evaporation from the insect must have altered the blood or tissues of the mosquitoes and had an unfavourable effect on the development of the parasite. It should be stressed, however, that conditions in this experiment differ from those met with in Nature, where the mosquito might be able to get access to drinking water however low the relative humidity of the environment might be. In this sense the results are only of academic interest and should not be applied to natural conditions.

The effect of temperature in my experiments only shows that at high temperatures (25° C.) the rate of growth of oocysts is faster than at lower temperatures (18° C.). The size of oocysts at 25° C. is always larger, although both batches of mosquitoes were fed on the same bird on the same day.

Analysis of Heteroploidy Produced by Chloracetophenone

THE problem of demonstrating and analysing the degree of ploidy of non-dividing cells is continually arising in different contexts, for example, in cancers, or giant cells in tissue culture. Chromosome counts may not be available in such material, and recourse must be had to indirect methods such as those reviewed by Fankhauser and Humphrey[1], including measurement of cell and nuclear volume, nuclear spacing, projected areas of uncountable mitotic figures, counts of heterochromatic spots and maximum number of nucleoli. Huskins demonstrated polyploidy in non-mitotic plant cells by inducing them to divide with 3-indole acetic acid and counting chromosomes. None of these methods except Huskins's[2] are entirely independent of prior study in the same material of tissues of known degrees of ploidy, and one of the most reliable methods (maximum number of nucleoli) breaks down when applied to limited material or to mixed tissues of varying ploidy. The interesting paper of Biesele, Poyner and Painter[3] utilizes and reviews indirect methods in respect of polyploidy and the related condition of polyteny in mouse cancers, but on plentiful material and with the assistance of chromosome counts.

The necessity of finding a reliable indirect method was encountered while examining tail-tip preparations of *Rana temporaria* tadpoles which had been subjected at the gastrula stage to $5 \times 10^{-6} M$ chloracetophenone. In untreated tadpoles, the nuclei of pigmented and unpigmented epidermal cells are thin disks of equal mean projected area. In treated tadpoles the unpigmented cells are unaffected: the pigmented cells and nuclei, however, although normally differentiated, were giant and non-mitotic, and some cells were polynucleate. For various reasons the indirect methods referred to above were all impracticable or inconclusive; at least pentaploidy was indicated (maximum number of nucleoli five), and cell and nuclear size suggested a degree of heteroploidy between tetra- and octoploid.

It was found that a much more precise analysis of ploidy could be effected by an empirical approach involving consideration of the numbers of nucleoli and their projected areas as measured on *camera lucida* drawings. Six types of nucleus were examined

Table of mean nucleolar areas in epidermal cells of *Rana* tadpoles. Projected areas of nucleoli measured in cm.^{2} under linear magnification 1,780. For each mean a preliminary analysis (where relevant) gave no significant differences within nuclei. Age counted from day of treatment (gastrulation)

Group	Type of cell	Number of nucleoli per nucleus	Mean area per nucleolus ± S.E. of mean: number of nucleoli measured in brackets. Age of tadpoles:		Combined mean nucleolar area (unweighted)
			4-day	8-day	
I	Diploid	2	0·123 ± 0·021 (16)	0·109 ± 0·006 (14)	0·11
	Giant	4	0·101 ± 0·007 (16)	0·111 ± 0·007 (12)	
II	Giant	3	0·146 ± 0·011 (18)	0·136 ± 0·008 (9)	0·14
III	Diploid	1	0·240 ± 0·025 (8)	0·220 ± 0·031 (7)	0·22
	Giant	2	0·180 ± 0·017 (16)	0·245 ± 0·022 (16)	
IV	Giant	1	0·355 ± 0·030 (4)	0·464 ± 0·025 (10)	0·41

in uninucleate cells, namely, normal diploid (unpigmented) cells with either one large or two small nucleoli per nucleus, and giant (pigmented) cells with one, two, three or four nucleoli per nucleus. The mean areas of the nucleoli in each type of nucleus were determined in two tadpoles of different age, as shown in the table. *t*-Tests show that the data for each tadpole fall into four groups; means in any one group differ from means in other groups; means within a group do not differ. The only exception among the various comparisons is that Group II in the 4-day tadpole does not quite attain a significant level of difference from the highest member of Group I and the lowest of Group III.

As well as falling into groups, the data also indicate a simple and striking proportion between nucleolar areas. The total nucleolar area (that is, the product of mean nucleolar area and number of nucleoli per nucleus) is uniformly about twice as great in giant nuclei as in diploid nuclei. These results can only be explained by a condition of tetraploidy in the giant cells. The combined areas in the last column for Groups I, II, III, IV are close to the 1 : 1⅓ : 2 : 4 proportion, which would be expected in such circumstances.

One of the only two 5-nucleolate nuclei was present in one of these tadpoles: the nucleoli approximated closely to two of Group I size and three of Group III size, indicating, therefore, octoploidy.

In the light of these results, cell and nuclear areas which had been measured in these and sixteen other tadpoles could now be interpreted; the mean areas were much the same in all tadpoles, and the effect of chloracetophenone was therefore of general occurrence. In addition, some analysis of polynucleate cells could be made; for example, cells with two tetraploid nuclei were found, and the occasional presence of small non-nucleolate nuclei indicated the occurrence of aneuploidy.

It is thus possible to state with some certainty that chloracetophenone applied to frog gastrulæ gives rise in the tadpole to epidermal cells which are mainly tetraploid, together with some octoploidy, aneuploidy, and combined heteroploidy and polynuclearity. This is interpreted as evidence of interference with the spindle mechanism.

As the method of determining ploidy is purely empirical, based on differences and identities in the data, it may well prove of some general use. The fact that a simple proportion existed between total nucleolar area in a nucleus and the degree of ploidy was a fortunate accident which simplified the interpretation; but the demonstration of tetraploidy in Groups I and III at least would be unaffected by a more complicated proportion such as might occur in other material.

Chloracetophenone is known to be a specific inhibitor of all enzymes the action of which depends on —SH groups[4]; the bearing of this on the production of heteroploidy and other effects in Amphibia is at present under investigation.

Cytoplasmic Bud Formation in Hymenopteran Spermatogenesis

Many early workers on hymenopteran parthenogenesis describe the formation of a cytoplasmic bud and its pinching off during the first spermatocyte abortive division. Earlier observations were tabulated by Sanderson[1], to which may now be added the following:

Group	Species	Abortive division	Authority
Braconidæ	*Habrobracon juglandis*	Bud pinched off	Torvik-Greb[2]
Cynipidæ	*Neuroterus baccarum*	No bud pinched off	Dodds[3]
Ichneumonidæ	*Acnoplex smithii*	Bud pinched off	Koonz[4]
Ichneumonidæ	*Spilocryptus extrematus*	Bud pinched off	Koonz[5]
Tenthredinidæ	*Diprion polytomum*	No bud pinched off	Smith[6]
Sphecoidea	4 species	No first division	Whiting[7]

The phenomena have often been discussed from an evolutionary point of view, White[8] expressing the situation thus: "The functional significance of these cytoplasmic phenomena is far from clear. The bees are morphologically the most 'highly evolved' group of the Hymenoptera but they have preserved a remnant of the first meiotic division that has been lost in the far more primitive sawflies. Yet when we come to the second meiotic division the bees seem to have acquired a specialized mechanism whereby the cytoplasm is unequally distributed to the two spermatids one of which is functionless."

In sawflies (Tenthredinidæ) Sanderson[1] was unable, despite repeated search, to be satisfied that such cytoplasmic buds were freed, stating: "Appearances would indicate that cytoplasmic buds are freed, but closer examination reveals that these bodies are merely sections through the cytoplasmic bridges by which the spermatocytes are bound together, the 'Zellkoppelungen' and 'Interzonal bodies' of German and American authors respectively."

The seeming anomalies in Hymenoptera therefore led me to devote great attention to these buds during studies on spermatogenesis in the sawfly *Pteronidea ribesii*. In sections it is extremely difficult, if not impossible, to say with certainty whether the 'buds' are sections of bridges or not. With mounts of fresh material, however, this doubt can be resolved, for one of the most striking appearances in a mount of testis at the maturation stage is the number of free anucleated cytoplasmic buds. Examination of unruptured cysts clearly shows that these buds are

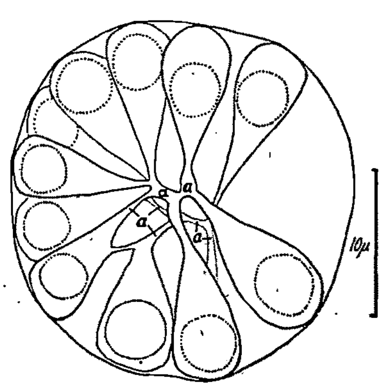

Fig. 1. Cyst of pear-shaped first spermatocytes at interkinetic stage. *a*—Cytoplasmic bridges

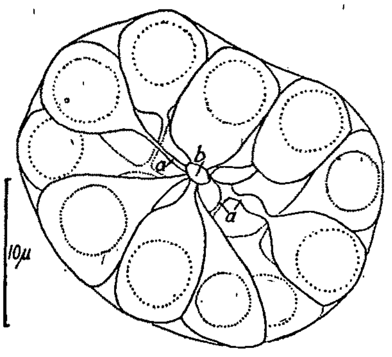

Fig. 2. Cyst of first spermatocytes about prophase stage. *a*—Cytoplasmic bridges, *b*—adherent bud

present in large numbers in cysts of spermatids but are few at the anaphase and metaphase of the second division and, except in a few cysts, are not found before this division.

Whether a bud is freed or not at the end of the abortive (first) division can in my opinion be satisfactorily interpreted for *Pteronidea ribesii* as follows.

The first spermatocytes are roughly pear-shaped and have their apices directed toward the centre of the cyst, the cells being connected by cytoplasmic bridges containing the 'interzonal' or 'cell-coupling bodies' (Fig. 1). At prophase and metaphase the cell shape is more rounded, or even spherical if space allows, and the cytoplasmic bridges appear as in Fig. 2. It would seem that the substance of the 'interzonal body' is more viscous than the cytoplasm of the cell body, so that the rounding of the cells causes the bridges to become more attenuated, some occasionally breaking and causing the formation of buds attached to the cells and containing the 'interzonal body' substance. The axis of the abortive spindle is usually radial, and at telophase there is a slight elongation of the cells along this axis so that they once more become predominantly pear-shaped (Fig. 3). The changes indicated in Fig. 4, *a–d*, have been observed when a cell with a cytoplasmic bud once more is connected with other cells, re-forming cytoplasmic bridges at the telophase of the abortive division. The telophase chromosome clump resolves itself into the chromosomes of the second metaphase plate, and the cell once more rounds itself as far as space in the cyst allows. This rounding is far more pronounced than in the first division, and therefore causes the rupture of more cytoplasmic bridges and the consequent appearance of quite a number of cells at the metaphase stage with cytoplasmic buds (Fig. 5) adherent. The axis of the second division is at right angles to the first division spindle, and therefore at approximately right angles to the cytoplasmic bridge process or bud. The elongation of the cells at anaphase and their subsequent cleavage into spermatids result in the separation of some of these cytoplasmic buds or in spermatids with buds adherent (Fig. 6).

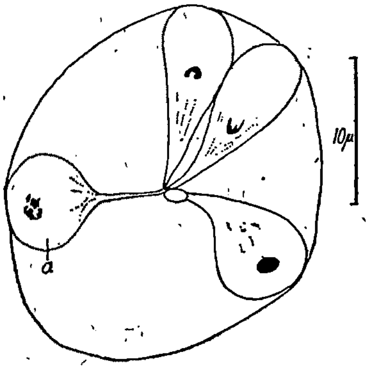

Fig. 3. Cyst showing three cells at abortive telophase stage and cell '*a*' more advanced and entering second metaphase stage

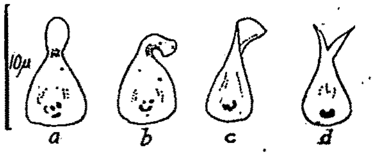

Fig. 4. Successive stages of a cell from anaphase, *a*, to telophase, *d*, of abortive division, showing cytoplasmic bud in *a* eventually bifurcating in *d* to reform cytoplasmic bridges with two other cells

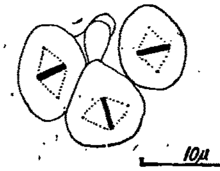

Fig. 5

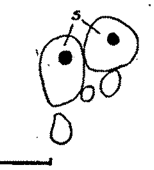

Fig. 6

Fig. 5. Cells at metaphase of second division, two with buds

Fig. 6. Free buds from cyst of spermatids, two shown adhering to spermatids, *s*

Meves and Duesberg[9], regarding *Vespa crabro*, in opposition to Mark and Copeland (who find the buds to be freed at the beginning of metaphase), state that they find the buds attached to the mother cell at anaphase of the second division. From Meves and Duesberg's description and drawings, and from Meves's[10] observations on the honey-bee, I conclude that the above interpretation might also explain their findings.

The formation of cytoplasmic buds, freed or not, during maturation divisions, at least in the sawfly *Pteronidea ribesii* if not in other and more highly evolved Hymenoptera, can, I think, be more satisfactorily interpreted as the result of the 'sticky' property of the cell coupling (interzonal) body interfering with the mechanics of cell division during the rounding of the cell at metaphase, and has not the evolutionary significance commonly attributed to it, namely, that it is a remnant of cytokinesis.

I wish to thank Prof. A. D. Peacock and Dr. Ann R. Sanderson, University College, Dundee, for their active interest in my work; Prof. C. M. Yonge, University of Glasgow, for laboratory accommodation; and the Carnegie Trust for financial assistance.

Identity of the Shell Pigment of *Haliotis cracherodii* Leach

In 1903 Schultz directed attention to the blue, acid-soluble pigment which occurs in the shells of the Californian abalone. Subsequent studies by Schultz, Schultz and Becker[1], Kodzuka[2] and Lemberg[3] have further subdivided the pigments present; but there has been no agreement as to their identity. Schultz, in his later papers, pointed to the similarity between the visible absorption band of the main pigment ($\lambda_{\max.}$ 622 mμ) and that of the known indigos, and Lemberg identified the pigment provisionally as a pyrrole body, since its solubility in dilute acids is greater than that of most indigoids. The pigment is known to give a strong colour reaction with nitrites and with fuming nitric acid. There has been doubt about the exact nature of this reaction, and about the number of pigments responsible for it.

Using a technique of chromatography on talc, and starting with acid extracts (in 2*N* hydrochloric acid) of shells of *Haliotis cracherodii*, of which Schultz's *H. californiensis* is a variety, we have obtained clear-cut separation of the pigments on the column into a lower green, brown and violet series, some of which give reactions typical of bilitrienes, and a main blue fraction corresponding to Lemberg's pigment *B*. We further purified this main pigment by chromatography of amyl alcohol extractives from the original acid solution, and produced a homogeneous fraction which could not be resolved on the column. Details of this preparation will be published elsewhere.

The reaction of the blue pigment with nitrite is not typical of Gmelin's bilitriene reaction; it is, however, closely similar to that given by indolylacetic acids (Nencki–Sieber test), and the amyl alcohol-soluble product of the reaction gives a visible absorption, plotted on the Beckmann spectrophotometer, which resembles that recorded for the urorosein pigments by Homer[4], by Watson[5], and by Rimington, Holiday and Jope[6].

Haliotis derivative		Urorosein (Watson[5])
Ammonium hydroxide:	522–492	555–557 mμ
Hydrochloric acid:	559–550, 540–490	544, 511

Urorosein from indolylacetic acid (Homer[4])
552–531, 505–492
from indolylaceturic acid
579–539, 502–485

In view of these findings, a specimen of the blue pigment in chloroform–cyclohexane was examined for fine structure in the ultra-violet region, using a Hilger medium quartz spectrograph and a hydrogen arc source, and the resulting bands compared with those of indigotin. The following results were obtained:

	Haliotis blue	Indigotin
Bands $\lambda_{\max.}$ (A.)	3570	3560
	3370	3370
	3226	321
	3070	3070
	—	2856
	—	2745

These results confirm the view of Schultz and Becker[1] that the pigment is closely related to indigotin, and is not a pyrrole; in its solubilities it differs considerably from the known[3] indigos, being considerably more soluble in aqueous acids even than the N—N′ dialkyl indigos. Details of its behaviour, and of the concomitant pigments, will appear elsewhere.

The finding is of interest in view of the occurrence of substituted indigos in the eggs and hypobranchial gland of many Stenoglossa. Pigments of this type have not previously been detected in the lower gastropods.

Acknowledgment is due to Prof. C. Rimington for his kindness in providing access to the Beckmann spectrophotometer, and to E. M. Jope, of the London Hospital Spectrographic Department, for examining and reporting on the ultra-violet spectrum of the substance.

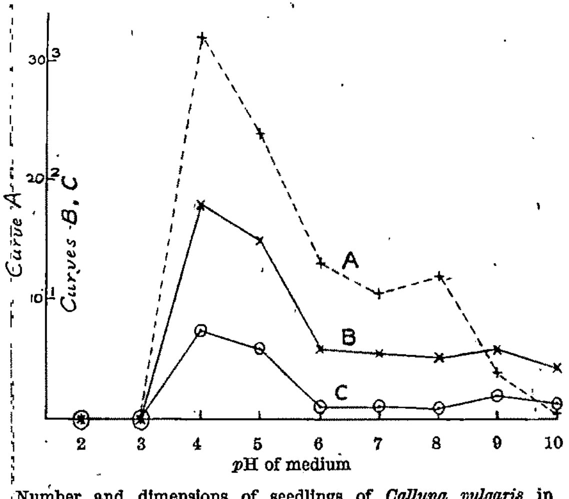
Germination and Development of Heather and the Hydrogen Ion Concentration of the Medium

Several workers[1-3] have shown that, in the field, heather (*Calluna vulgaris* Salisb.) is found most frequently and attains its maximum development on soils the reactions of which are about *p*H 4. I have examined the germination and the subsequent seedling development of *Calluna* seeds planted on agar media adjusted to give a range of reactions. A quantity of 1 per cent British agar was prepared with a form of Knop's solution. This was divided equally between nine flasks. The contents of these were adjusted to *p*H 2, 3, 4, 5, 6, 7, 8, 9 and 10, respectively, by the addition of the requisite quantities of sulphuric acid or caustic soda. After adjustment, the agar in each flask was poured into six 1-in. boiling tubes to give a depth of agar of about 1½ in. The tubes were plugged and the agar allowed to set. A liberal sowing of *Calluna* seeds was then made in all tubes.

After six weeks, germination was found to have occurred in all the cultures, although, in most cases,



Number and dimensions of seedlings of *Calluna vulgaris* in relation to *p*H. (*A*) Mean number of seedlings; (*B*) average of mean shoot-lengths (cm.); (*C*) average of mean root-lengths (cm.)

it had not proceeded beyond the stage of emergence of the radicle. Seven months after sowing, the seedlings in each tube were counted; also, the lengths of roots and shoots were measured. The means of these data for the six tubes at each reaction are plotted against pH in the accompanying graph. The bimodal form of curve A is clear, and a tendency to the same is perceptible in curves B and C. Others have observed this phenomenon in studies of the relations of various species to hydrogen ion concentration.

This experiment, which was performed in the Botany Department at the West of Scotland Agricultural College, confirms the field evidence that the optimal reaction for *Calluna* is in the region of pH 4. Above this level, not only do the germination of seeds and the growth of seedlings decline, but also chlorosis is progressively more marked. Even at pH 5, severe chlorosis of the tips occurred. Local rises in soil reaction might thus account for the frequent appearance of chlorotic heather plants in the field.

Occurrence of a Species of *Clymenella* Verrill (Polychæta, fam. Maldanidæ) on the North Kent Coast

McIntosh[1] states that "the representatives of the Maldanidæ are met with but seldom in British waters, and in the majority of instances only fragments are secured". In fact, a study of the literature reveals that many species, and even genera, are described from preserved material, often in a fragmentary condition. It is of interest to record, therefore, that a fairly large maldanid is moderately common in the intertidal zone at Whitstable near the ordinary low-tide mark.

The worm belongs to the genus *Clymenella* Verrill, and this is, so far as I can find out, the first record of a member of this genus occurring on the coasts of Britain, or, for that matter, on the coasts of Europe. Fauvel[2], it is true, describes a *Clymenella* (?) *cincta* from Manche (Dinard), but notes that "Cette espèce n'étant connue par un seul fragment antérieur de 12 sétigères, il n'est pas possible, vu l'absence de la région postérieure, de préciser exactement à quel genre elle appartient".

Monro[3], in discussing the genus *Clymenella*, points out that there are two groups of species included in that genus, "the *torquata, rubrocincta, somersi* and (?) *elongata* group, with anterior *uncini* differing little, if at all, from their normal *uncini*, and the *minor, cincta* south-west Australian and Indian Ocean *Clymenella* sp. group, with anterior ventral *acicular hooks*".

The maldanid found at Whitstable clearly belongs to the *torquata* group and more closely resembles *Cl. torquata* than any other species. It may prove to be a new species; but this cannot be decided until a comparison has been made with specimens of *torquata* obtained from America. *Clymenella torquata* and its allied species are reported solely (?) from the coasts of North America, and it is possible that the Whitstable maldanid may prove to be a recent immigrant comparable in this respect with *Urosalpinx cinerea* and *Crepidula fornicata*.

A description of the worm is in course of preparation.

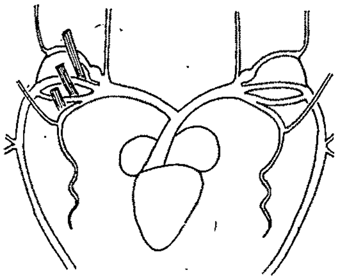
Persistent Fifth Arterial Arch in the Frog

A RARE abnormality in the arterial system of the common frog was found in a male specimen from Cornwall. The fifth aortic arch persisted on both sides of the animal and was patent. Carotid, systemic and pulmo-cutaneous arches were normal; but the fifth arch branched off from the pulmo-cutaneous. It joined the systemic arch laterally and was large and open. Right and left sides were symmetrical. A ligamentum aortico-carotideum was present. The relation of the posterior petro-hyoideus muscles was as follows. The internal carotid artery slipped beneath, that is, dorsal to, the first petro-hyoid muscle, the systemic arch dorsal to the second, and the abnormally persistent arch dorsal to the third, thus preserving the regularity of arrangement which is lost when the fifth arch disappears during development.



Rana temporaria. Male. Heart and arterial arches. The left carotid, systemic, persistent fifth and pulmo-cutaneous arches are shown, with the ligament connecting the internal carotid artery and the systemic arch. The right arches are similar, and the first, second and third posterior petro-hyoid muscles have been drawn in position

So far as I am aware the abnormality described has not been recorded on *both* sides of an adult frog. O'Donoghue[1] gave an account of a persistent fifth arch on the left side of a male, without reference to the musculature, and in his specimen a true ductus caroticus was present.

Abnormalities in the venous system are much more common, and among this group of a hundred frogs three exhibited persistent lateral abdominal or posterior cardinal veins.

A NEW TYPE OF BETATRON WITHOUT AN IRON YOKE

By A. BIERMAN

Philips Research Laboratories, Eindhoven

BY far the most expensive and the heaviest part of betatrons, as usually constructed, is the iron yoke with its complicated pole-pieces. We propose to describe a mode of construction which uses no yoke, and which, though restricted in its applications, offers several important advantages over the original type of betatron.

The main features of our betatron are two coils in series, with a sealed-off glass acceleration tube between them. The dimensions are chosen so as to fulfil the well-known condition $0 < n < 1$, n being determined by the radial decrease of the magnetic field, which is assumed to be proportional to r^{-n}. The flux required within the electron orbit is attained by means of a small iron core placed in the axis of the coils. This iron core is inserted inside the 'Pertinax' tube, visible in the photograph. Saturation of this core effects contraction of the orbits towards the end of an acceleration period, until the electrons strike a tungsten target 0·1 mm. thick. The core, made of transformer sheet-iron, is interrupted half-way by a small gap which is so adjusted that the contribution of its stray field makes $n = \frac{1}{2}$ over almost the entire area of the electron orbits.

The dimensions of the tube are hence not restricted by pole pieces, and have been made very large. The inner wall of the tube is covered with a transparent, fluorescent semi-conductor, which has proved valuable for investigating the behaviour of the electron beam at different magnetic field-strengths and the effects of parasitic fields. Moreover, the transparency of the tube is very convenient for the glass-blower, while the electron gun and the target are being sealed into their precise positions. The electron gun is small both in the axial and radial direction; hence its chance of being struck by electrons is less than with the usual type of construction.

If simplicity of equipment is desired, we may forgo the advantage of short-pulse injection and take a sinusoidal injection voltage from an auxiliary coil placed on the axis of the main coils (shown on the left of the photograph). The tension induced in this coil amounts to several kilovolts, from which the injection voltage can be tapped off at various points.

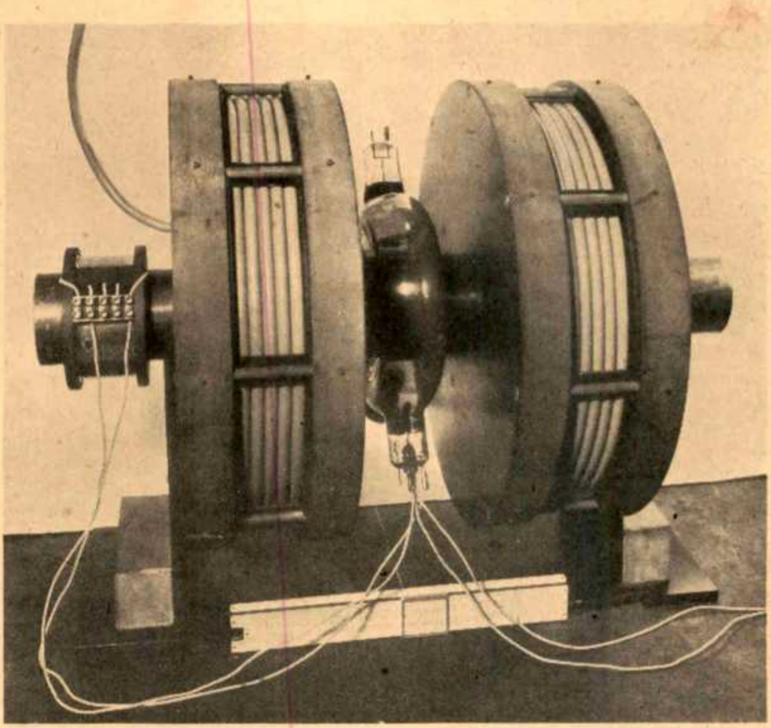
The current through the coils is supplied by discharging a 6·5 μF. condenser via a spark gap. The condenser is continuously loaded from a rectifier, and the spark gap breaks down as soon as the voltage across the condenser reaches a value of about 50 kV., so that the discharges are automatically repeated at intervals of a few seconds. It is also possible to arrange for a single discharge at a fixed moment, as is, for example, required for Wilson camera exposures.

Each discharge initiates damped oscillations with a frequency of 2,500 c./sec., in which the peak current through the coils attains a value of about 5,000 A. The power needed to maintain undamped oscillations would, with the present construction, be several thousand kilowatts, which makes continuous operation impossible because the dissipation would then be far too high. The small apparatus, shown in the photograph, is therefore only capable of producing radiation pulses at intervals of at least one second. Since after a few complete oscillations the current has been so much reduced that the iron core is no longer sufficiently saturated, only a few periods can be utilized in each discharge.

Though the mechanical forces resulting from the very heavy currents demand a solid construction of the coil frame, the betatron as a whole weighs no more than 50 kgm., the iron core itself weighing less than 5 kgm.

As the peak value of the magnetic field is 0·4 V.sec./m.^{2} (4,000 gauss) and the radius of the orbit is 8 cm., the energy of the accelerated electrons amounts to 9 MeV. This value can be reduced by exchanging the core for a smaller one which is saturated at lower currents; the contraction of the electron orbits will then take place at an earlier phase of the discharge. In this case a greater number of periods are utilized in each discharge.

It will be clear that in experiments requiring short-wave X-ray output during a brief period (as, for example, nuclear processes investigated with a Wilson camera) this type of betatron offers distinct advantages. Its simple construction makes the cost low, and it is light enough to be comparatively easy to handle;



9-MeV. betatron without an iron yoke. Slide-rule against base gives the scale it can, for example, be mounted on a mobile support. Moreover, the intensity of the radiation produced is greater than with the customary betatrons, for several reasons: because of the high frequency, the energy-gain in each loop is considerable (240 volts); this effects strong damping of the oscillations about the equilibrium orbit, while, moreover, the total path of the electrons is not more than 30 km. Consequently the loss of electrons by impact against the wall or against the molecules of the residual gas is considerably smaller than at the lower frequencies commonly used. In addition, a greater number of electrons can be accelerated at a time, owing to the large dimensions of the acceleration tube. Lastly, the axial symmetry of the magnetic field is more perfect than in an apparatus with pole pieces arranged in sectors, which again reduces the loss of electrons. Reliable data on the intensity of the radiation are not as yet available, but our experiments have already yielded evidence that the peak intensity is much higher than that obtained, in this laboratory, with a betatron of the customary type.

MULTIPLICATION AND DIVISION BY ELECTRONIC-ANALOGUE METHODS

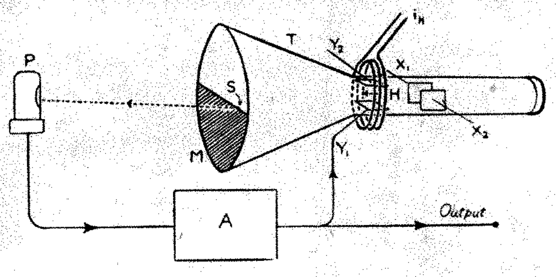
By E. M. DEELEY and D. M. MACKAY
Wheatstone Laboratory, King's College, London

THE product or quotient of two rapidly varying quantities is difficult to obtain by conventional electronic-analogue methods. Desirable features in a multiplier include: (*a*) symmetry of response to positive and negative inputs; (*b*) an *absolute* indication of zero input, with consequent freedom from zero drift; (*c*) independence of normal changes in electronic characteristics; (*d*) rapidity and accuracy of response.

Techniques such as amplitude-, frequency- or pulse-modulation adapted from the field of communications have so far failed to provide all these features; most are fundamentally incapable of doing so. The object of this note is to direct attention to a simple principle which has been found to meet the above requirements[1], and which seems to invite wider application in this and related fields.

It is most easily described as a development of the principle used in J. J. Thomson's familiar method of measuring electron velocity, in which the force on an electron moving with velocity v at right-angles to a magnetic field H is counteracted by an electrostatic field E proportional to the product $H \times v$. If the adjustment of E were automatic and instantaneous, its value would be a continuous measure of this product.

The cathode-ray tube, which is well known to possess potentially all four virtues above, forms a convenient basis for experimental work. In Thomson's arrangement, however, v was the axial velocity of the electron stream, which is not a widely variable or reversible quantity. Accordingly, in the practical form of multiplier shown in essentials in the accompanying diagram, an axial magnetic field is used and v is the *transverse* velocity of the electron stream in the X-direction, proportional to a voltage V_x applied to conventional deflecting plates X_1, X_2. After X-deflexion, the stream passes through the magnetic field H, which produces a deflecting force, initially in the Y-direction, proportional to $H \times V_x$.



The Y-deflexion of the spot S on the screen, which would normally result (corresponding to a rotation of the pattern), is counteracted by a photo-electric feedback system of the type used in function-generators[2,3]. The photocell P, coupled to one of the Y-plates via the amplifier A, prevents the spot from deviating by more than a fraction of its diameter from the edge of the mask M. With care in adjustment of the latter, the spot can thus be held closely to the X-axis, and V_y is then proportional to the product of V_x with the current i_H producing H. Conversely, if the photocell is used to control H and voltages V_x, V_y are applied to X and Y plates, the current i_H is proportional to the quotient V_y/V_x.

Since the important parameters other than the accelerating voltage are purely geometrical, the prospects of attaining high stability in a device of this kind are good. Output is sensibly independent of changes in the gain of A, as usual in feedback circuits. At a later stage, it is hoped to dispense with the photo-electric link, using a collecting-electrode inside the tube to perform the combined function of cell and mask.

At the time of writing, it has not been possible to make a fair test of the accuracy and frequency-range of the technique; but it may be of interest to summarize the encouraging results of preliminary experiments with quite crude apparatus. A 931—A photomultiplier has been used, with a cathode-ray tube having a blue screen and running at only 500 V. to enhance overall sensitivity; D.C. and sinusoidal inputs up to 10 kc./sec. have been multiplied over the ranges ± 300 mA. and ± 20 V., with an accuracy of the order of 2 per cent at 50 c./sec.

Accuracy is limited in practice fundamentally by the signal to noise ratio attainable in the feedback path. Other important factors are the uniformity of the axial field, and its effective axial length, which should not greatly exceed that of the Y-plates. If magnetic X-deflexion were used, the Y-voltage would be practically independent of 'gun' voltage; but if electrostatic X-plates are employed for the sake of their high impedance, the output is directly proportional to the square root of the gun voltage, the stability of which is then an important factor in overall accuracy.

The importance of such devices to the physicist and mathematician lies chiefly in their application to the solution by analogue methods of differential equations with non-constant coefficients. A number of further applications of the same principle to high-speed electronic computing technique are being developed, and a fuller account of these and the above will be published elsewhere.

[1] MacKay, D. M., Brit. Prov. Pat. Spec. No. 11161 (1948). The same principle has been the subject of an unpublished independent investigation by D. J. Mynall.

THE SMITHSONIAN INSTITUTION

REPORT FOR 1946–47

THE annual report of the Board of Regents of the Smithsonian Institution for the year ended June 30, 1947,* has now been published as a bound volume, including, besides the secretary's report and that of the executive committee, reports on the United States National Museum, National Gallery of Art, Freer Gallery of Art, Bureau of American Ethnology, International Exchange Service, National Zoological Park, Astrophysical Observatory, National Air Museum, Canal Zone Biological Area, and the Institution's library and publications. In a general appendix are reprinted a series of papers, some original, ranging over such diverse subjects as large sun spots, atomic energy, the use of isotopes as tracers, silicones, new products of the petroleum industry, drowned ancient islands of the Pacific basin, the biology of Bikini Atoll, the senses of bats, the influence of insects on human welfare, mosquito control tests, the primary centres of civilization, and the performance of propeller and reaction-propelled aeroplanes.

The reports from the National Air Museum and the Canal Zone Biological Area are the first to be included since these came under the administration of the Institution. The former, established in August 1946, is concerned mainly with the acquisition of a storage depot for the temporary assembly of material for the Museum. The latter includes the biological laboratory on Barro Colorado Island, which has already been responsible for much valuable scientific work. Some account of this work during the past twenty-four years is included in the present report. Studies cover the testing of wood for proofing against termites, the tropical deterioration of plywoods, textiles and packaging containers, and the effect of fungi on optical glass. Biologists go to the island regularly to study the fauna and flora, and there is a herbarium of 1,533 mounted specimens, as well as a species index containing about 7,000 entries. In addition to rainfall, temperature and relative humidity observations for 1946, the report records trials demonstrating the possibility of using treated timbers to build a termite-free house even where termites are extremely abundant and active.

Nearly 757,000 specimens went to the United States National Museum during the year, including two large and outstanding collections of fishes; but one of the most promising features of the year's work was an opportunity to resume field investigations of fifteenth-century historic Indian village-sites and some of the early Spanish settlements in the West Indies. Field studies were also made in Guatemala on the highland Maya for comparison with the lowland Maya of Yucatan; a survey of the fishery resources of Guatemala was continued and a botanical survey made of St. Vincent. The Bureau of American Ethnology continued the River Basin Surveys instituted in 1945 to recover archæological and palæontological information and materials which would be lost through the construction of dams and large reservoirs in many of the river valleys of the United States. Surveys in the Missouri Basin have been followed by others in Georgia, Virginia–North Carolina, Texas, California and the Columbia–Snake basin, while other investigations related to Eskimo anthropology, an Arctic Bibliography and Roster, the social organisation and ceremonial life of the Seneca nation, and cultural affinities between the northern Iroquoians and the Cherokee of the Great Smoky Mountains. Packages received by the International Exchange Service for transmission increased by 163,296 to 703,798, and the lag due to the War has been decreased to 69,020 lb. Consignments are forwarded to all countries except Roumania and Yugoslavia.

A slight improvement in the supply of animals for exhibition enabled the National Zoological Park to replenish the stock; but although some physical improvements were made, the Zoo was still understaffed. A list of additions and of animals, birds and reptiles in the Park is appended. The Division of Astrophysical Research was concerned first with appraisal of the solar constant values received from its field stations, with planning and developing improvements in instruments and methods, and with Camp Lee measurements of sun and sky radiation. The Division of Radiation and Organisms concentrated its work on the role of light, especially the wave-length effects, on the fixation of carbon by green plants, and on the influence of light on plant growth and development, particularly the mechanism of dormancy in light-sensitive seeds and the developmental physiology of grass seedlings. Of 62,137 accessions to the library, 14,607 went through the International Exchange Service, and 1,693 books were purchased. Like other departments of the Institution, the library was seriously handicapped by insufficient staff and accommodation, and overcrowding and lack of funds for binding caused progressive deterioration of its fine collections.

IODINE AS A MEANS OF DEVELOPMENT IN PAPER CHROMATOGRAPHY

By Dr. GUNNAR BRANTE
Institute of Medical Chemistry, University of Uppsala

IN a search for an agent for revealing the position of choline and other N-methylated alkanolamines separated by chromatography on papers, iodine was found satisfactory. It can be either directly sublimed on to the dried paper or sprayed in alcoholic solution, both methods having their special advantages. During the sublimation or spraying, spots of a brown to yellow colour develop, and they grow more distinct when any excess iodine or solvent is fanned away. Inspection in ultra-violet light sometimes makes the border-lines of the spots more easily discernible. As fading rapidly sets in, the spots are best judged immediately and outlined with pencil. After some heating or hanging at room temperature, the colour of the spots caused by most substances disappears completely. New iodine treatment then again reveals them.

After disappearance of the iodine, the same paper may, without any disadvantage, be developed by some other agent, for example, ninhydrin, the hexosamine reagent according to Morgan and Elson, general sugar indication reagents (ammoniacal silver

* *Rf* values indicate the ratio between the distances of the substance and the solvent fronts from the initial position of the substances.

† 20 parts of water-saturated n-butanol mixed with 7 parts of water-saturated phenol were separated and the upper layer used in the trough.

nitrate, m-diphenylendiamine), picrate solution. After ninhydrin treatment, a paper may be developed by iodine (preferably by spraying) with similar results as though ninhydrin had not been used.

A great many nitrogen-containing compounds examined (in spots in most cases containing about 20–30 μgm. of substance) gave positive reactions of varying intensity and quality. I was especially interested in certain amines and their N-methylated derivatives, known or expected to be constituents of lipids. Most of the substances tested of this class gave very distinct and characteristic brown to flame-coloured spots. But various amino-acids, guanidine bases, pyrimidines, purines, etc., also were coloured, though in most cases much more faintly. Subsequent to iodine development most amino-acids gave the usual purple colour with ninhydrin; but some, for example, tryptophan, histidine and cysteine, retained iodine for a long time, thereby modifying the ninhydrin colour to a browner tint.

The method may be of value in qualitative analysis of mixtures containing only a few positively reacting substances. Thus it was found very suitable for my own purpose, namely, a study of nitrogenous constituents in lipid hydrolysates (to be published elsewhere). Data for some solvents used in these studies are collected in the accompanying table. Several other solvents have been tested and found less useful; thus it may be mentioned that in water-saturated phenol alone the methylated amines move unduly fast, and that nitrogenous solvents, due to their own reactivity with iodine, must be very thoroughly removed before iodine treatment, and therefore some of them are less convenient.

Due to their volatility, trimethylamine and dimethylaminoethanol do not appear at all, monomethylaminoethanol only with reduced strength on papers run in neutral or alkaline solvents in air. After adding one or two per cent of acetic acid to the solvent, the foregoing substances will be retained in the paper. Such solvent mixtures are now being studied.

Hitherto I have examined mainly substances which might be expected to be constituents of lipids or contaminants in lipid extracts. Purines and pyrimidines, owing to their slight solubility and faint iodine reaction, will probably not lead to errors in lipid analysis by the iodine reaction. On the other hand, the strongly reacting creatinine was identified in a distinct spot, deriving its origin from an alcoholic fraction of a lipid extract of a brain in uræmia.

In the table may be noticed several examples of the influence on its chromatographic behaviour of an OH- or CH_3-radical entering into a substance. This may be of some guidance in interpreting unknown spots.

Also in quantitative experiments with paper chromatography, iodine may prove convenient by revealing the position of the substances to be estimated; particularly as the iodine later sublimes, leaving outlined spots for excision, soaking and chemical or physical determination.

The ready formation of iodine addition compounds by amines and amine derivatives seems to be the cause of the iodine reaction, at least in most instances.

VISUAL AIDS TO EDUCATION

THE application of visual aids to education has been stimulated during the last decade mainly because the value of the still and motion picture projectors is being increasingly realized. Visual aids have existed for a long time; but it is only comparatively recently that their significance as an educational medium has been fully appreciated. This was recognized by the Havard Report on "General Education in a Free Society", which states: "Traditionally language deputises for what has to be absent. It tells us what we might see or hear. But it too often gets in the way of, or replaces, all that could give it a meaning. Now that the things and events themselves can be brought to us, the role of language is reversed. Instead of words having to explain or represent things, it is rather things or actual processes taking place before us, which explain words or call them in question."

To-day visual aids to illustrate and explain the written or spoken word are commonly used in the form of pictures, charts, diagrams and plays, while there is a growing interest in, and use of, still and motion pictures. The use of the latter in education was discussed by Mr. R. Beloe, chief education officer of Surrey County Council, in his address to the Education Section of the British Association at

Brighton. The address has now been reprinted by the National Committee for Visual Aids in Education.

Considering the place of the filmstrip projector as the successor to the old magic lantern, Beloe suggests that this device may be increasingly used, not so much as an aid to a lesson but as a lesson in itself, emphasis being placed more on the image seen than on the words read or spoken. More than the radio it could be used to project into hundreds of classrooms the identical ideas of a single teacher; every school should have its filmstrip library.

Yet however vast the potentialities of still pictures in education, those of motion pictures, which entertain for good or ill some 250 million human beings weekly, are even greater, particularly when full use may be made of natural colouring. Various investigations before 1939 recorded the value of the film in teaching. It helps children to remember; it awakens interest and secures sustained mental concentration; it stimulates, by putting a point of view different from the teacher's, and by compelling the pupil to find his own words to express opinions and to describe scenes; it supplies material for the exercise of reasoning faculties. In other words, it can enlarge the experience and broaden the outlook of pupils, and bring a sense of reality into the classroom. It can also broaden the outlook and knowledge of teachers and act as a stimulus to them.

By 1939, therefore, any doubt about the film's value as a teaching tool had vanished from the minds of those who had closely studied the matter. The real problem was one of logistics, and, until this was solved, little progress could be made.

The position was described in a 1946 report by Political and Economic Planning, from which it was made clear that there was a vicious circle. Lack of good educational films led to reluctance on the part of local education authorities to equip the schools with projectors. As there was, therefore, only a small market for educational films, it was not an economic proposition to produce them in great quantity. Recently it has been estimated that there are some two thousand instructional films of varying quality, types and value available in Great Britain. A large number of these, although for want of something better labelled as 'educational', are practically useless for teaching purposes. So far as can be ascertained, in 1946 there were fewer than four hundred sound projectors in schools in England and Wales. Of the 1,700 silent projectors available, many were unsuitable for classroom use.

These shortages of suitable films and projectors were due less to lack of enterprise than to lack of means. In the United States, where money is available, it has been stated that in the city of Los Angeles there are more than double the number of sound projectors in the whole of Great Britain. During the War the use of films by the armed forces of the British Commonwealth and also of the United States, as well as the lessons which had been gained from excellent documentary and propaganda films, again focused attention on the merit of the film as a teaching aid and on the paucity of supply.

In 1945 there was every reason on educational grounds why progress should swiftly be made in developing the use of visual aids by methods of projection as an integral part of teaching method. The lead was taken by the County Councils' Association, which, together with the Association of Municipal Corporations and the Association of Education Committees, as well as the National Teachers' Association, submitted a memorandum to the Minister of Education. As a result, two committees were set up in 1946. One, named the National Committee for Visual Aids in Education, was made up of representatives of teachers and local education authorities and had the duty of planning a visual education policy, collecting and collating views, nominating practising teachers as educational advisers to the producers of films, developing regional film libraries and encouraging authorities to purchase suitable films, advising on the supply, selection and maintenance of suitable apparatus and carrying out research. But the essence of the scheme was to be found in the Committee's relationship with the Minister. The Committee was to determine the films which are needed, and the Minister, subject to reasonable safeguards on the score of economy and the national interest, was to commission the films through a Production Committee, on which the National Committee, the producers of visual material and apparatus, the Ministry itself and the Central Office of Information were to be represented. The films thus produced were to be purchased by the authorities and schools.

At first the Central Office of Information was made responsible for the placing of films in production; but, in order that all suspicions of propaganda should be removed, it was later decided to set up a new organisation which would replace the Central Office of Information so far as educational films and other visual material was concerned. This body, the Educational Foundation for Visual Aids, is independent of the Government and has been supplied with a loan of £130,000, which is repayable to the Exchequer. Its function is, first, to market and distribute the films and other material which have already been commissioned.

Where commercial producers are prepared to take the financial risk of making a film they will be able to do so, and the Foundation will include the film in its catalogue of films, which it will supply at the stated price, receiving a discount from the production company. Where no producer is willing to take the financial risk the Foundation may either commission the film and retain the rights, or place with the producer an advance order for enough copies to enable him to finance the project. It is expected that, if necessary, the Foundation will take similar action with filmstrips.

Thus there has now been set up machinery to find out what films the schools require, for placing the work with the producers and for enabling both great and small to produce them, for providing the producers with advice from a practising teacher during production, and for marketing and distributing the finished articles.

Much more still remains to be done. First, there must be local libraries of all films likely to be in constant use by the schools, with facilities for teachers to view them. Secondly, there must be set up regional libraries for less widely required films. Thirdly, there must be a similar catalogue of filmstrips; but of these a library is needed in each school, for they are comparatively cheap and easily stored. Nevertheless, a central collection so that teachers may see what can be purchased for their schools will be needed in each authority's area.

Fourthly, the projectors for showing the material must be made available for purchase and must be purchased by local education authorities.

Fifthly, the local education authorities must make arrangements for the repair and servicing both of films and of apparatus.

Sixthly, but by no means least important, the teaching profession must be shown how to handle the medium. Up to the present the filmstrip and the film have been used mainly by enthusiasts. All teachers whose lessons can be improved by the use of visual aids should be trained to use them. It is therefore incumbent on all local education authorities to provide teachers with the facilities for acquiring that ability.

Lastly, a great deal more information based upon careful research is needed before educationists can regard themselves as masters of this medium. Scotland has produced two valuable reports which contain important statements about the subjects on which films should be made, the length of film suitable for children of various ages, and the value of sound films. These conclusions and others formulated in the 1947 Progress Report of the National Committee for Visual Aids in Education need testing. It is perhaps most important of all to ascertain the value of the film in teaching children of differing grades of intelligence and of its use in the teaching of adults.

T. H. HAWKINS

SUMMER SCHOOL IN ELECTRICAL ENGINEERING AT RUGBY

DURING July 12–16, 1948, the British Thomson-Houston Co., Ltd., held, at its Rugby works, a summer school in electrical engineering, which was attended by members of the staffs of the electrical engineering departments of universities and technical colleges, together with representatives of the Service colleges, the Ministry of Education, the Institution of Electrical Engineers, and Government research organisations. In the "Proceedings" of the school, published recently by the Company, are recorded the scientific papers presented by members of the Company's staff.

These papers give an interesting cross-section of the activities of a large electrical manufacturing organisation. Materials, for example, are represented by two papers, one on magnetic sheet-steel and the other on modern developments in electrical insulators. A review is given of some of the mechanical problems affecting the design of electrical machines. Several papers deal with design problems of the magnetic and electric circuits of rotating electrical machinery and one with the design of insulation for high-voltage transformers. Power systems receive attention in papers on switchgear, protective gear and power system analysis. Rather more than half the papers are concerned with electronics or high-frequency phenomena and applications. The fundamental theory of communication forms the subject of one paper, and magnetron generators, pulse modulators and micro-wave transmission techniques are covered by a group of papers. In the field of electronics there are contributions dealing with fluorescent discharge-lamps, arc control in gas-filled valves, the application of the mass spectrometer to leak detection in high-vacuum systems, and a development of the betatron.

One of the most valuable features of this collection of papers is the indication given in many of them of the trend of development and of the directions in which research in university departments could contribute towards the solution of some of the more fundamental problems. Having regard to the fact that these lectures were prepared by members of design and development departments as well as of the research department, it is perhaps worth while to record the impression that the scientific requirements of design and development are scarcely less stringent than those of research. Of particular interest is the opening address given by Sir John Cockcroft, in which the needs of Great Britain for scientific and technical staff are reviewed.

THE AGORA OF ANCIENT ATHENS: A STUDY IN ARCHÆOLOGICAL RECONSTRUCTION*

By PROF. HOMER A. THOMPSON
Institute for Advanced Study, Princeton

THE excavations which are being currently conducted by the American School of Classical Studies in the Agora, or civic centre of ancient Athens, have led to the identification and restoration of many ancient buildings through the combination of evidence drawn from ancient authors, inscriptions and the exploration itself. As a specimen to illustrate the procedure, the Odeum, or Concert Hall, may be selected.

The remains of the Odeum have been identified from a reference in Pausanias, the 'Baedeker' of the second century. Its date of construction is fixed in the Augustan period, partly by its architectural style, partly by the pottery associated with its foundations and partly by its specific name, the Agrippeum, which suggests that the building was erected by Agrippa, the minister of Augustus.

A close study of the foundations of the building and of scattered marble blocks from its superstructure has permitted the recovery of its architectural scheme in all essentials. The building proves to be unique in its dual nature, comprising as it did a core, in which were an auditorium, stage, dressing-room and lobby, and around the core a raised balcony that opened outward for the accommodation of spectators who might wish to view processions or ceremonies in progress outside the building. Of particular interest among the architectural details of the original period is the stage front, which was decorated with a marble screen supported by terminal figures alternately male and female.

The siting of the building on the axis of the Agora square is reminiscent of the contemporary Forum of Augustus in Rome, while its scheme of lighting through an open colonnade at one end was inspired by the Erechtheum; hence its design may be the work of a team of architects, some Greek and some Roman.

The building collapsed and was afterwards remodelled (as shown by stamped roof tiles) about A.D. 150. The remodelling involved reduction in the capacity of the auditorium from 1,000 to 500, and in the conversion of the original dressing-room into an open porch. The entablature of this porch was supported by six colossal marble figures, half of them Tritons and half Giants, both types being adaptations from statues of divinities in the pediments of the Parthenon. In front of the pedestals of these colossal figures were placed seated statues of philosophers. From the radical changes involved in the remodelling and from the fact that Philostratos (writing in the late second century) referred to the building as the scene of public lectures by the sophists, it may be inferred that in its second period the Agrippeum had become a university lecture hall and that its function as a concert hall had been assumed by the great new Odeum erected by Herodes on the south slope of the Acropolis about A.D. 160.

---

* Abstract of a Friday Evening Discourse delivered at the Royal Institution on February 18.

A century later (A.D. 267) the Agrippeum was burned down by a band of barbarians, the Heruli, who sacked this part of Athens. The area lay desolate until about A.D. 400. Then above the ruins of the ancient building was erected a huge complex in the nature of a gymnasium which, in accordance with the Greek practice, would also have served university purposes. In the façade of the new building were incorporated four of the colossal figures from the old. The great structure of A.D. 400 was abandoned in the sixth century, presumably in consequence of the Emperor Justinian's edict closing the University of Athens (A.D. 529), and its ruins were buried by silt. Early in the nineteenth century three of the colossal figures were rediscovered and later re-erected, to be known as the 'Stoa of the Giants', one of the most prominent landmarks in the city and one of the most enigmatic until its riddle was solved by the current excavations.

TRAINING FACILITIES IN INDUSTRIAL RADIOLOGY

THE need for extending the available training facilities in industrial radiology was discussed at a meeting of the Industrial Radiology Group of the Institute of Physics held on February 18, at which were representatives of inspecting authorities, technical institutions, the Ministry of Education and industrial firms.

Discussing the necessity for adequate training of industrial radiographers, Mr. J. C. Rockley (Aeronautical Inspection Department) explained the system adopted by the Department, by which certain industrial radiographic departments and the radiographers in charge are 'approved' after satisfying the Aeronautical Inspection Department that the apparatus available is satisfactory for the intended purpose and that the radiographer has received sufficient basic training to be competent. A feature of this system is that if the radiographer moves to another department, his 'approval' is automatically withdrawn; the 'approval' of the department would also be withdrawn pending the appointment of a qualified successor.

Mr. F. C. Cocks (Lloyd's Register of Shipping) explained that the principal requirements for surveyors and other officers of inspecting authorities are provision for acquiring the technical background and experience in interpretation of radiographs necessary to satisfy themselves on the quality of the radiographic examination, and to assess the effect on the structure examined of an internal defect the shadow of which is seen on the radiograph.

Mr. F. Y. Poynton (Northampton Polytechnic, London) reviewed the present position with regard to technical institutions. Only very few technical colleges—among them the Northampton Polytechnic, London; the Royal Technical College, Glasgow; and the technical colleges at Chesterfield and Wednesbury—possess X-ray apparatus suitable for radiography, and none of these has equipment operating above 100 kV. peak. Most of the industrial radiography carried out, however, falls within the range of 150–400 kV. peak, or utilizes gamma-radiation; and it is under these conditions that most of the practical problems associated with scattered radiation, radiographic sensitivity and protection occur. Mr. Poynton said that steps are being taken to provide facilities for training in industrial radiography at the Northampton Polytechnic, London. The detailed form of these courses has still to be worked out; but considerable progress has been made in the provision of apparatus and the necessary laboratory and darkroom equipment.

Dr. L. Mullins described the courses being run by Kodak, Ltd., and explained that the basic introductory course occupies two weeks (75 hours) with an optional third week. This period has been adopted as the minimum in which the fundamental theoretical and practical training can be given, and because industrial firms are generally reluctant to release their staff for a longer period. He also mentioned more advanced courses in casting and weld radiography, lasting two weeks, and in shipbuilding radiography occupying three weeks.

Mr. N. Tunstall (Ministry of Education) said that the Ministry is anxious to participate so far as the demand for training facilities justifies; but it is very desirable that industry should make clear to local colleges the extent and nature of the demand for such facilities. The provision of short intensive courses would be a departure from the more usual method of training in a 'laboratory art', which is usually catered for by a course of part-time study lasting two years. The question of awarding a certificate of competence at the end of a full-time course of two or three weeks duration is one requiring a particularly cautious approach. H. S. Tasker

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, April 23—Saturday, April 30

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 10 a.m.—Public Exhibition of "European Housing in Prehistoric Times".*

Monday, April 25

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Prof. Adrien Albert: "Selective Toxicity with special reference to Chemotherapy".* (Further Lectures on May 2, 9, 16, 23, 30 and June 8 and 13.)

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. H. C. Walker: "Present Century Advance in Marine Engineering Science" (Science and Marine Navigation, 3).

Royal Institute of Chemistry, London and S.E. Counties Section (at Medway Technical College, Gardiner Street, Gillingham), at 7.30 p.m.—Mr. P. H. Prior: "Some Experiences of a Chemist in the Paper Industry".

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Prof. George B. Cressey: "China's Prospects".

Tuesday, April 26

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. J. G. Peristiany: "Social Structure of the Pokot (Suk)".

Manchester Geographical Society (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. Harry Milligan: "South Devon Story".

Institution of the Rubber Industry, London and District Section (at Caxton Hall, Caxton Street, London, S.W.1), at 7 p.m.—Annual General Meeting; Dr. L. R. G. Treloar: "Rubber Physics Up-to-Date".

Sheffield Metallurgical Association (at 198 West Street, Sheffield), at 7 p.m.—Dr. K. Hoselitz: "Permanent Magnet Alloys".

Tuesday, April 26—Friday, April 29

Institute of Welding (at Beach Hotel, Southsea).—Spring Meeting.

Wednesday, April 27

Textile Institute (in the Public Hall, Lune Street, Preston), at 10 a.m.—Annual General Meeting; Sir Frederick Bartlett, F.R.S.: "The Application of Psychology to the Textile Industry" (Mather Lecture).

Physical Society, Low Temperature Group (at the British Oxygen Co., Research and Development Department, Lombard Road, Morden Factory Estate, Morden, London, S.W.19), at 2.30 p.m.—Dr. P. H. Sykes: Introductory Lecture; Dr. P. M. Schuftan and Mr. A. M. Clark will outline the work of the Development and Research Sections respectively.

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Annual General Meeting; Prof. H. H. Read, F.R.S.: "Time in Plutonism" (Presidential Address).

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. J. Bronowski: "Some Uses of Statistics in the Building Industry—an Investigation into the Erection Times of Nine Types of Non-Traditional House".

Institution of Electrical Engineers, North-Western Radio Group (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Discussion on "Audio-Reproduction" (to be opened by Mr. G. J. Scoles, Mr. A. G. F. Smith and Mr. G. I. Thomas).

Royal Statistical Society, North-Eastern Group of the Industrial Applications Section (at the Chemical Industries Club, 18 Lovain Place, Newcastle-upon-Tyne), at 6.30 p.m.—Mr. N. J. Squirrel: "Statistical Tables in Quality Control".

Institute of Industrial Administration, Manchester Centre (in the Reynolds Hall, College of Technology, Manchester), at 7 p.m.—Mr. J. N. Toothill: "Productivity of the Engineering Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Lawrence Bragg, F.R.S.: "Giant Molecules".

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1).—Conference on "Combined Heat and Power Supplies".*

Thursday, April 28

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Exhibition Meeting.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. G. Polya: "Symmetrization".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Dr. Hugh Dryden: "The Aeronautical Research Scene—Goals, Methods and Accomplishments" (Thirty-seventh Wilbur Wright Lecture).

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.15 p.m.—Scientific Papers.

British Institute of Radiology (at 32 Welbeck Street, London, W.1), at 8.15 p.m.—Dr. F. G. Spear: "The National Radium Commission in Retrospect" (Silvanus Thompson Memorial Lecture).

Friday, April 29

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Presentation of James Watt International Medal, and Special Lecture by the recipient, Dr. Fredrik Ljungström of Sweden.

Royal Statistical Society, Birmingham Group of the Industrial Applications Section (in the Chamber of Commerce, 95 New Street, Birmingham), at 6.30 p.m.—Mr. E. D. van Rest: "Sequential Sampling".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Chemistry—The Principal, Wigan and District Mining and Technical College, Wigan (April 29).

Physicist—The Secretary, Romford Group Hospital Management Committee, Oldchurch Hospital, Romford, Essex (April 30).

Lecturer in Chemistry—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (April 30).

Director of Research (to be responsible for the control of technical research under the headings of Engineering, Metallurgy, Chemistry, Textiles, Paints, etc., as well as General Research)—The Secretary, Railway Executive, 222 Marylebone Road, London, N.W.1 (April 30).

Assistant Lecturer or Lecturer (Grade II) in Botany (Plant Physiology)—The Registrar, University College, Southampton (May 1).

Lecturer or Assistant Lecturer in Mathematical Statistics, and an Assistant Lecturer in Applied Mathematics—The Registrar, The University, Liverpool (May 1).

Lecturer (Grade I or Grade II) in Physics—The Secretary, The University, Birmingham 3 (May 1).

Assistant Director—The Director, Solar Physics Observatory, Cambridge (May 4).

Lecturer in Education (with qualifications in Science, preferably Chemistry or Biology), an Assistant Lecturer in Physics, and an Assistant Lecturer in Mathematics—The Registrar, University College, Leicester (May 7).

Mathematicians, Physicists and Aeronautical Engineers (unestablished Senior Scientific Officer and Scientific Officer grades) at the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.438/48A (May 7).

Professor of Botany—The Secretary, University College, Cork (May 7).

Lecturer (on probation) in the Department of Zoology and Comparative Anatomy—The Registrar, University College, Cathays Park, Cardiff (May 12).

Assistant Lecturer (temporary) in Agricultural Zoology—The Secretary and Registrar, University College of North Wales, Bangor (May 15).

Organic Chemist as research assistant to the Professor of Medical Chemistry, Australian National University, Euston Road, London, N.W.1—The Administrative Office in the U.K., Australian National University, Africa House, Kingsway, London, W.C.2 (May 19).

Head of Establishment (male) at the Air Ministry Survey Production Centre, Teddington—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2508 (May 19).

Lecturer (Grade III) in Electrical Engineering—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 20).

University Demonstrator in Metallurgy—The Secretary, Appointments Committee of the Faculty of Physics and Chemistry, University Chemical Laboratory, Pembroke Street, Cambridge (May 21).

Junior Lecturer in Mathematics—The Secretary, University Registry, Oxford (May 23).

Chair of Geography at the London School of Economics and Political Science—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 25).

Chair of Botany at Royal Holloway College, Englefield Green—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 30).

Lecturer (with qualifications in Electronics) in the Fluid Motion Laboratory—The Registrar, The University, Manchester 13 (May 31).

Demonstrator in the Department of Entomology—The Assistant Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1 (May 31).

Nuffield Studentships and Fellowships for experimental and theoretical research in Nuclear Physics—The Professor of Natural Philosophy, The University, Glasgow, W.2 (May 31).

Home Office Inspectors (2) under the Cruelty to Animals Act 1876 (experiments on living animals)—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 2504 (May 31).

Lecturers and Senior Lecturers in Physics—The Secretary of University Court, The University, Glasgow (May 31).

Lecturer in Physics—The Secretary, The University, 38 North Bailey, Durham (May 31).

Laboratory Steward in the Physics Department—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18.

Lecturer in Chemistry—The Registrar, Municipal College, Portsmouth.

Fisheries Officers in the Federation of Malaya, and in East and West Africa—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Abstractors to deal with technical and scientific literature relating to textiles, and a Librarian—The Director, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester 20.

Technical Assistants in Royal Ordnance and Atomic Energy Factories and other Establishments, for investigation (under direction of senior engineer or chemist) of problems connected with either the production, development or maintenance and service sides of the factories and preparation of reports—The Ministry of Supply, Est.2(E)1, Room 403, Adelphi, London, W.C.2.

Technician (mainly to assist in research work) in the Department of Experimental Physiology—The Professor of Physiology, Medical School, Newcastle-upon-Tyne.

Assistant Librarian—The Secretary, British Internal Combustion Engine Research Association, 111–112 Buckingham Avenue, Slough, Bucks.

Junior Chemists or Physicists to supervise work involving chemistry and/or applied physics in the Division of Atomic Energy (Production) at Springfields Factory, Salwick, Lancs., and Windscale Works, Sellafield, Cumberland—The Staff Section, Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington.

Research Worker to conduct experiments in the biological aspects of 25 MeV. X-Rays and electrons—The Director, Cancer Clinic, City Hospital, Saskatoon, Sask., Canada.

Experimental Officer for two years' research on the physics of the pick-up of airborne droplets by flying locusts—The Director, Anti-Locust Research Centre, British Museum (Natural History), Cromwell Road, London, S.W.7.

Photographer for medical (non-clinical) and scientific work—The Secretary, Department of Physiology, School of Medicine, Leeds 2.

Graduate Chemist for work on the development of the use of wool grease and its by-products in the leather industry—The Director of Research, British Leather Manufacturers' Research Association, 1–6 Nelson Square, London, S.E.1.

Physicist, Chemist, or Engineer, to be responsible for the measurement and control of radiation hazards throughout the factory area, in the Division of Atomic Energy, Windscale Works, Sellafield, Cumberland—The Ministry of Supply, Division of Atomic Energy, Risley, Warrington, Lancs.

Chemists (2) for research concerned with the control of agricultural pests by chemical means, particularly by soil fumigation—Dr. A. B. P. Page, Imperial College Field Station, Silwood Park, Sunninghill, Berks.

UNIVERSITY EDUCATION IN NATURAL SCIENCE

THE problems of education in science and of education through natural science were considered by scientific men and schoolmasters at the Dundee meeting of the British Association, and similar problems at the university level have now arisen in the University of Cambridge. A 'Syndicate' has been reviewing the regulations for the Natural Sciences Tripos, and the discussion of its report in the Regent House on February 22 showed that many in Cambridge have misgivings about the scientific education now being given to undergraduates. A number of tutors, directors of studies and college supervisors urged the need for drastic reforms. The position at Cambridge is probably similar to that at many other British universities, and merits the attention of all who are interested in the training of scientific men and citizens. Many of those who are closely in touch with the life and work of undergraduates are convinced that science students are being given so much formal factual teaching that they have no time for reading and reflexion. The study of the wider and more cultural aspects of their work is precluded and their intellectual development retarded. The courses of instruction seem generally designed for the production of specialist research workers; and specialization seems on the increase, in spite of the fact that only a small percentage of the students who read science become professional scientific workers. It seems to be overlooked that many will become teachers in schools, some will go into the Civil Service, others will join the administrative staffs of business or manufacturing firms; such students need a wider and more general training.

The present position in the universities of Great Britain has grown up gradually, often in the absence of any definite policy to guide the planning of the instruction given. In the past, the content of university courses in natural science was much smaller and there was less specialized science-teaching in the schools; students possessed some knowledge of the art of reasoning either through a study of elementary logic or, at least, through several years of regular lessons in Euclid. But the steady progress of scientific discovery has led to an enormous increase in the fields which students are expected to cover; both at school and at the university, philosophical instruction has been largely replaced by practical training. To-day a good memory rather than a well-trained mind seems to be the key to success. As a result, a science student may gain a high place in examinations, and yet be a very ignorant person when compared with many students of the humanities; and it has been said that the outside activities of young scientific men often show lamentable absence of that spirit of critical inquiry and resistance to propaganda which might be expected in those trained in exact knowledge.

Science students form a large proportion of the present undergraduate population of Great Britain, and they should contribute much to the future intellectual life of the country. We cannot afford to tolerate a system which produces a mass of narrow specialists for the sake of the few who may become workers in a particular scientific field. Graduates in science should have the well-trained minds and the breadth of vision which will enable them to take up administrative posts or to teach the principles of scientific thought in schools, as well as the details of some branches of scientific knowledge culled from text-books or from their lecture notes.

With the introduction into the schools of the new examination for a General Certificate of Education, it will probably be necessary for many university syllabuses to be revised. When this revision occurs, it is to be hoped that the question of education through science will receive careful consideration. Every university should provide some instruction in the methods of scientific thought and procedure—the grammar of science. How many of our undergraduates could to-day show the use of inductive and deductive reasoning in the subjects which they are studying, or give examples of hypotheses the reliability of which depends on the truth of postulates ? A training in the methods used to discover the truth about the phenomena of Nature should teach the student how to try to discriminate between truth and falsehood in the ordinary affairs of life. Some knowledge of the history of science is also of considerable importance ; not the kind of history which consists mainly of the dates when significant discoveries were made, with short biographies and anecdotes of great men of science, but a study of the historical background of science. Something of real educational value could be obtained from a knowledge of what men thought about Nature in the past, of the problems which confronted the natural philosophers, of the methods used for investigating these problems, and the difficulties which had to be met owing to imperfect apparatus, faulty observation or mistaken pre-suppositions. It is not suggested that the whole field should be covered, but only selected periods or subjects connected with the student's main lines of study. Lieut.-Colonel H. D. Anthony's book, "Science and its Background" (reviewed in *Nature* of September 4, 1948), shows that such a study can be made both interesting and useful; this mode of approach ought to be further developed at a university level. Sir William Dampier's "A History of Science" (Camb. Univ. Press), of which a fourth edition has recently appeared, is a standard work which must also be considered. An educated man of science should have some knowledge of the part which his own branch of study has played in shaping the material, intellectual and social progress of mankind. Many schoolmasters have realized the educational value of teaching about the operation of scientific progress as the greatest factor in the making of the modern world, but comparatively few young men who have taken university courses in science are competent, on leaving the university, to take an effective share in such teaching.

The problems of specialization also need close study. Too often a high degree of specialization in science begins at school, and no new subjects are studied at the university. This may set the student upon a path which he is not fitted to follow, and it often limits his education both as a citizen and as a man of science. The man who has only been trained in the physical sciences may fail to grasp the problems which arise when scientific methods are applied to heterogeneous living populations ; on the other hand, the student without a training in physics and chemistry may well be incapable of following modern experimental work in biology.

The reorganisation of university teaching along the lines which have been suggested will not be easy. It is not merely a question of introducing new courses into an already over-loaded time-table. The whole scheme of instruction needs review, with particular reference to the teaching of students during their first two years at a university. There may be considerable reluctance in some places to consider changes in the long-established routine; but it is vital to the nation that the thousands of men and women now studying science should be trained in the best possible manner. These students will in time become responsible for the progress of scientific knowledge, for our health, our food and for the education of our children; they will contribute to the administration of factories and commercial undertakings ; some of them will become Civil Servants, politicians and journalists. It is vital to ensure that students are imbued with a desire to ascertain truth by scientific reasoning, in order to fit them to give of their best in a world which is being deluged with propaganda of every kind.

PERSONAL AND HUMAN FACTORS IN INDUSTRY

Teamwork in Industry

By F. J. Burns Morton. Pp. xii+273. (London Chapman and Hall, Ltd., 1948.) 18*s*. net.

THIS book in essence is an essay on the theme o leadership, in the sense of which Arthur Bryant wrote in "Years of Victory", of evoking the will t serve rather than a mere matter of transmittin orders. "Unless we can discover and implement," writes Mr. Burns Morton, "means to ensure that me work willingly and harmoniously together, ou industrial efficiency will diminish, and with it ou trade in the home and foreign markets." The boo is frankly a contribution to the thinking and organisation which are indispensable factors in removin the present threat to our industrial future. Th approach is pragmatic but fundamental, and Mr Morton will clearly judge the worth of his work b the extent to which it contributes to the solution o what is now generally admitted to be the key proble in productivity—the establishment of right huma relations in industry.

Mr. Morton is fully aware, with Dr. Mayo and suc leaders in the theory of scientific management a Mary Follett, Colonel L. Urwick and Sir C. C. Renold that such relations involve society as a whole as we as the relations between management and th operatives within an industry. With his purpose o stimulating thought rather than offering cut-and dried solutions to particular problems, Mr. Morto directs his readers to most of the more stimulatin and accessible earlier works in this field. There are indeed, a few surprising omissions, and sometimes h asks rather much of his reader. A chemist, for example, might perhaps locate the late Prof. C. H. Lander's Melchett Lecture in the *Journal of the Institute of Fuel* without much difficulty; but the ordinary reader may well be at a loss for a clue in either time or space, if he wishes to verify or amplify Mr. Morton's brief quotation.

In his twelve chapters he ranges over such subjects as the human factor, team-work, job satisfaction, selection, training, incentives, leadership, supervision, discipline and social organisation. He starts by examining the causes of present difficulties, and passes in turn to review the social and economic changes which have taken place, to question the suitability of old methods for new problems and to outline the character of human behaviour. Here he insists on a change in policy or some adjustment in administration, there some modification in organisation or the introduction of new methods; throughout he insists on the necessity for training, from executives downwards, for more research in social psychology and industrial management, and for a widespread appreciation of human behaviour.

It would be easy to criticize some of Mr. Morton's observations as platitudinous; and some of the principles he emphasizes are well known, and are conspicuous in the planning that lay behind the successful operations of the War. Such criticism would be unjustifiable. Far too many of the precepts here displayed are still commonly ignored in industry. Moreover, Mr. Morton has here restated more incisively, in a form much freer from jargon and more attuned to British ears, much that is to be found in more diluted form in the vast American literature of management.

As the title of his book suggests, Mr. Morton sees the solution to our problem of productivity in the creation of team-work in industry. This he regards as a spontaneous reaction to environment and circumstances, secured voluntarily and not imposed from above; inspired by example in leaders, it is likely to follow rather than precede collaboration in the executive. It is concerned with external as well as internal relationships, and is a technique applicable primarily to the executives and not to be left to the single influence of a personnel manager. It can be developed by suitably planned measures and should not be left to chance. Its purpose, like that of management, is to make the most use of the man-power available.

The truth of Mr. Morton's diagnosis could easily be demonstrated in the experience of nationalized industry in Britain over the last two years. There the fundamental problem of human factor in industry—Can men be induced to strive efficiently as individuals and to work effectively as a group ?—is still unsolved. He would be a bold man who would contend that the National Coal Board has yet succeeded in creating the circumstances which encourage men to do as much as they can instead of as little as they must. It is equally clear that nationalized industry, no more than private industry, cannot confine its attention to problems of production and neglect for long its social obligations without risk of unfavourable reactions. It is still true, as Mr. Morton observes, that competition is necessary; it is the conditions under which competition operates that decide its value.

The book abounds in suggestive observations. Have we yet realized the implications of the vast difference between the casual attention of the repetition worker and the absorbed interest of the skilled technician ? This may only be a variation on the theme of craftsmanship, but it bears closely not merely on the creation of co-operation and team-work, but also on selection, the satisfaction a man finds in his job, on training, and on the negative as well as the positive aspect of incentives. Again, how obvious are the principles for giving orders which he lays down in his chapter on supervision, but how often they are ignored! Mr. Morton rightly holds that we need to examine the whole process of giving orders, to build up a technique for the use and guidance of executives in making themselves more effective and their subordinates more efficient.

This is but one of many suggestions for investigation or even research which Mr. Morton makes. On all these subjects he writes with insight, and nowhere more than on the problem of leadership and the conditions in which it can function. False ideas on such matters as joint production committees are dispelled, and if Mr. Morton lays the chief responsibility on the executives of industry for creating the conditions in which effective team-work is possible, he indicates what else is required, and the contribution to be made by trade unions and other bodies. A wise policy in which the idea of service is clearly to be seen can do much to evoke the response required from all engaged in the industry or firm; and this book can make a valuable contribution to the thought on which such a policy must be based and the constructive action required at so many points to deal with the problems arising out of human relations in all phases of industry and at all levels.

R. BRIGHTMAN

A REFLEXION OF SCIENTIFIC AND TECHNICAL PROGRESS

A Century of Book Publishing, 1848–1948

Pp. vii + 74 + 12 plates. (New York and Toronto: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1948.)

A HUNDRED years ago David Van Nostrand opened his bookshop in New York. Many of the customers were his personal friends, who came to discuss with him the merits of the latest books; and in a few years his office became more like a literary club than the bookshop of to-day. So popular was it that in five years he was obliged to move to more spacious quarters.

During a stay in New Orleans, Van Nostrand had come into contact with a group of distinguished army officers, and it is thus not surprising that when he opened his New York office there was a preponderance of military books, especially as the Mexican War had stimulated public interest in military history. At that time the functions of publisher and bookseller were not distinct, and as few technical books were written in the United States, the greater part of the business consisted of selling imported texts of high repute.

Van Nostrand soon became the largest dealer in scientific and technical books in New York, and then proceeded to extend his activities by publishing books which reflected the main interests of the period; thus some of the earliest, in the prospecting days, dealt with the mineral resources of the country. The threat of civil war gave an immense impetus to the demand for military and naval books, and Van Nostrand, appointed official publisher, issued a group which became classics.

From 1860 onwards, a new theme became apparent. This was engineering. Railway engineering was the subject of many notable books when railways and steel bridges were in course of development, but in the middle 90's this gave way to the rapidly growing science of electrical engineering. Civil engineering staged a revival about 1910, and was followed by mechanical engineering. Along with engineering, chemistry came to the fore, and works on the subject expanded at a remarkable rate. Nineteen books were listed in 1884, and more than two hundred in 1948. Not only the numbers but also the size increased. Scott's "Standard Methods" started with 870 pages in 1917 and the present fifth edition has 2,700. Chemistry received its main stimulus from the First World War, but it was not until 1925 that physics showed signs of expansion. In this case the chief development was due to the Second World War, the peak rate of production being reached in 1942 by a text-book on ultra high-frequency technique which was written in sixty days. 3,000 copies were reproduced by the offset process in 37 days and sold almost immediately. In two years 60,000 copies were sold.

The volume under review does not deal only with books; it gives an intimate picture of the working of the Company from the time when a normal edition was 1,000 copies, sold for more than twice their cost of production, to the present day with its planning and fierce competition. The personalities and achievements of the directors are set out at length, and it is difficult to avoid comparing David Van Nostrand at his roll-top desk discussing books with his customers by lamp-light, with the present group of distinguished men directing sales to unknown buyers. Is what we call progress really a measure of happiness? H. E. WATSON

ECOLOGY OF POTATO VIRUSES AND THEIR INSECT VECTORS

The Spread of Virus Diseases in the Potato Crop

By J. P. Doncaster and P. H. Gregory. (Agricultural Research Council Report Series No. 7.) Pp. 189. (London: H.M. Stationery Office, 1948.) 5s. net.

THIS is a substantial piece of work, born of war-time anxiety over possible inadequacy of potato seed supplies for necessary expansion in the acreage devoted to this crop. English growers import each year, from Scotland and Northern Ireland, enough seed to plant half their acreage. This is biennially discarded in favour of a 'change of seed'. There is no doubt about the general wisdom of this policy; but it is equally certain that many discarded stocks could have been grown for more than two years without serious deterioration.

An investigation of this possibility forms one of the major subjects of the present inquiry. We know that the spread of virus diseases, and particularly leaf-roll and rugose-mosaic or crinkle, brings degeneration of the stock. We have the results of numerous laboratory and greenhouse studies on these diseases. We had not, however, until the appearance of this report, an adequate idea of factors which influence the rate of spread of severe virus diseases in the lowland field. We still do not possess any practical method of assessing the suitability for further seed of a crop grown in ware-producing districts. There is a general indication, but a distinct lack of exact correlation, between the amount of virus spread and the numbers of virus-transmitting aphids. There are also incalculable variations between crop and crop.

A major portion of the report is devoted to the actual portrayal of results gathered faithfully by the authors and numerous collaborators, and condensed to intelligible proportions by the text-figures and appendixes. Of the four species of aphids regularly occurring on the potato crop—*Myzus persicæ*, *Aphis rhamni*, *Macrosiphum solanifolii* and *Aulacorthum solani*—the last two mentioned are deemed to play little part in transmitting leaf-roll and rugose-mosaic in the field. *Myzus persicæ* overwinters on peach and *Brassica* crops. A large amount of virus infection is probably accomplished by winged spring migrants; but Apteræ may be partly responsible at the peak of summer infection. *Aphis rhamni* overwinters on *Rhamnus*, though several heavy infections on potatoes have occurred in areas where buckthorn is rare.

The amount of infection within a crop depends far more on the number of diseased plants it contains than upon sources of infection more distant. Survival of diseased volunteer plants may bring about a large increase of virus. Fumigation of large plots with nicotine vapour destroyed the aphids, but had little effect on the spread of rugose-mosaic and leaf-roll. Probably the infection had already been effected much earlier in the year than is commonly supposed. The report, indeed, serves the useful purpose of turning our attention away from the summer maximum of aphids, and concentrating future work on insect-virus relations earlier in the season.

Though the report is somewhat negative with respect to its main target, it contains some very positive contributions along lines which might be called, without disparagement, by-ways to the main investigation. The chapter on development of the potato plant contains a lot of information which is relevant to the question of tuber-size control, now being developed so successfully in some seed-growing areas. The demonstration that a good deal of virus spread occurs much earlier in the year than was suspected may also find its greatest application in seed-growing areas. J. GRAINGER

PIG PRODUCTION IN GREAT BRITAIN

The Production and Marketing of Pigs

By H. R. Davidson. Pp. xvi + 535 + 96 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1948.) 30s. net.

THE British housewife has a weekly reminder of the poverty of the national larder in respect of pig meat; but she is not alone in regretting the recent drastic decline in pig production in Great Britain. Many farmers echo her regrets, and welcome, though cautiously, the signs that the agricultural stage is possibly being set for a real revival of pig-keeping as an essential and profitable part of British livestock industry. That there are now such signs makes this a singularly opportune time for issuing a comprehensive, and not unduly expensive, text-book on pig husbandry; and the opportunity is all the better served if authority in matter is matched with appropriate format, as it is here by Mr. H. R. Davidson and his publishers.

At last it is possible to give almost unqualified appreciation to a book in which the author seriously attempts to present a synthesis of modern work and ideas on nutrition, breeding and economics in relation to the management of a farm animal. From the width, and depth, of his experience as scientific worker and practical farmer, Mr. Davidson recognizes that animal husbandry is not just the sum of the components of breeding, feeding and management, but that the psychology of the animals as well as of their attendants enters into everyday problems and practices of stock-keeping. He recognizes also that the last words on any branch of husbandry are not yet said; he therefore adopts a strictly personal attitude in his treatment of data, observations and experiences, which adds to the usefulness of the book.

The scope is truly comprehensive. Part 1 reviews the general economic background of the British pig industry; it includes a series of analyses of the cost structures of pig enterprises and a particularly apt résumé of the history, and fate, of the pre-war marketing schemes for pigs and their products. Part 2, "Theoretical and Technical Considerations", brings together a mass of information on carcass qualities and trade matters, together with a valuable description of systems of carcass judging and evaluation; it gives a sensible presentation of the plain principles of nutrition, followed by a study of feeding practices, and proceeds to a discussion of the physiological, anatomical, and genetical aspects of pig improvement, and finally, to specific chapters on matters of housing and hygiene. Part 3 is devoted to critical accounts of the practical aspects of management, in which the author's experience is given as a helpful guide to the proper care and handling of pigs of all ages and stages.

The text is well and aptly illustrated by plates and diagrams; relevant data are conveniently tabulated for detailed consultation, or for neglect, at will; there is an extensive and appropriate list of references; and the index is effective. There are some, but only a few, minor typographical errors. Author and publishers have been remarkably successful in making available no mere compilation, but a work which, by reason of its judicial yet personal character and its range, sets a very high standard in literature suited to the needs of the progressive practical stockman, the agricultural student, and the scientific worker, as well as to the needs of the times. J. E. NICHOLS

RADON AND ITS APPLICATIONS

Radon

Its Technique and Use. By W. A. Jennings and Dr. S. Russ. (Published for the Middlesex Hospital Press.) Pp. x+222. (London: John Murray, 1948.) 18s. net.

It is a little difficult on reading this book to decide precisely for what class of reader it was designed. The treatment is, on the whole, elementary; but certain aspects of the subject, particularly those concerned with the technique of extraction, are dealt with in very great detail.

Certainly the first part of the book, where the subject of radioactivity is dealt with generally, will provide an excellent introduction to the non-specialist; and, with its clear exposition of the history of radon and its applications, it will convey to him something of the care essential in the handling of all radioactive substances.

The second part of the book is concerned with the details of the process of radon extraction. Separate chapters are devoted to the radium sources used, the extraction and purifying processes, the loading process, the measurement of gamma-ray activity and, finally, an analysis of the variation of content among groups of radon seeds. The treatment is didactic rather than critical. A wealth of detail is given of particular forms of apparatus, and a large number of numerical examples are given, illustrating methods of control and calculation. The methods described for the preparation of radon seeds are those that were used at the Radon Centre of the Medical Research Council; but little reference is made to the other method now used extensively, where the radon is led directly into gold capillary tubing.

The final section of the book deals with the medical applications of radon. Much of the classical treatment for dosage estimation with radioactive sources is given, and a number of nomograms and other types of graphical methods are described for the estimation of dose in particular techniques. A chapter on "Some Medical Considerations" is contributed by Mr. T. A. Green, whose methods of using radon are described in considerable detail. No attempt is made by the authors in this section to give a general survey of the ways in which radon is used.

Appendixes at the end of the book give some details of the recommendations of the British X-Ray and Protection Committee relating to radon, and some outline proposals for the lay-out of a National Radon Centre. Useful tables are also given of the rise with time of the gamma-ray activity of radon seeds and the hourly growth and decay of radon.

The book is well produced with clear diagrams and tables. The reviewer has noticed one or two small errors in the tables at the end. It contains much valuable information that is not collected together elsewhere; but some readers will regret that the authors chose to confine themselves to a discussion of particular methods and techniques rather than to make a comparison of methods and techniques in general.

ANTHROPOLOGY IN THE SOVIET UNION

Contributions to the Anthropology of the Soviet Union

Compiled by Henry Field. (Smithsonian Miscellaneous Collections, Vol. 110, No. 13: Publication 3947.) Pp. vii+244+5 plates. (Washington, D.C.: Smithsonian Institution, 1948.)

THIS compilation of the work of Russian archæologists and physical anthropologists covers a period of some ten years. The author is indeed to be congratulated on producing a volume which is absolutely indispensable for all archæologists and physical anthropologists outside the Soviet Union. One of the tragedies of the present world political situation is the lack of contact between Soviet researchers in these sciences and the rest of the world. How far any conclusions reached are coloured by their political theories of to-day cannot be discussed in this review; but certain it is that greater personal contacts would result in a greater understanding, not only of all the fine work which is being accomplished, but also in the attitudes of mind of researchers to their work.

The continued use of cultural terms—Clacton, Azilian, and the like—for cultures in Russia and the Crimea is also a matter needing discussion. The tendency in the West is to consider that these cultures have no wide distribution and that elsewhere at the same time other, sometimes allied but not identical, cultures occurred. The Gabrielle de Mortillet system was created for the situation in France; it strains and creaks when it is extended to apply to the whole world. Up to the recent War, the Roumanians took their culture in large part from France; but the resulting culture and the people of Roumania were not French. So many of these problems could be settled if greater contact with our Soviet colleagues was possible, and therefore we are indeed grateful to Mr. Henry Field, who has at least, in part, made liaison.

The volume deals first with the archæological situation in the Soviet Union, and later with the physical anthropology. It opens with an account of a conference called by the Academy of Sciences and held in Moscow during 1945, and which was attended by Mr. Field as the delegate of the Smithsonian Institution and other learned bodies in America. There follows an account of more than three hundred Stone Age sites recently investigated. Not all these are of world-shaking importance, of course; but many of them were entirely unknown to students outside the Soviet Union heretofore. The anthropological side, too, has not been omitted, and, besides a general account of recent work on the origin of the various inhabitants, there is a more detailed discussion arranged geographically of the different folk who people that vast area of the world's surface.

Certainly it is a volume to possess, and one can only hope that the author will continue to act as a 'liaison officer' until the happy day dawns when more direct contacts become easier. M. C. BURKITT

VIA SULPHONAMIDE

The Sulphonamides and Allied Compounds

By Dr. Elmore H. Northey. (American Chemical Society, Monograph Series, No. 106.) Pp. xxvii+660. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1948.) 75s. net.

THE chemists, Fritz Mietzsch and Joseph Klarer, and the pharmacologist, Gerhard Domagk, all working in the laboratories of the I.G. Farbenindustrie in Wuppertal-Elberfeld, synthetized and tested the first chemical compound to show specific chemotherapeutic protection in mice infected with lethal doses of hæmolytic streptococci. This historic occasion was probably early in 1931, since the German patent covering it is dated November 7, 1931. About a year later, on December 24, 1932, a patent was applied for to cover prontosil rubrum, a more effective compound, and this very great discovery must have taken place earlier in the same year. The first clinical report appears to be that of Dr. Foerster at the monthly meeting of the Dusseldorf Dermatological Society on May 17, 1933, and records the cure of a staphylococcal septicæmia in a ten-month-old boy by the use of prontosil ('Streptozon'). Late in 1935, Tréfouël, Tréfouël, Nitti and Bovet, at the Pasteur Institute, discovered that the chemotherapeutic action of prontosil, and of many similar molecules, was due to *p*-amino-benzene-sulphonamide, a metabolic product of prontosil. They went on to say, "The therapeutic activity of such a simple molecule which is itself not a colouring matter, opens the way to a systematic study of chemotherapy comparable to that which has been followed in the case of pentavalent arsenic". Time has clothed this scientific appraisal in the garb of classical understatement.

Domagk must have appreciated the significance of his great discovery, but he could scarcely have realized that he was ushering in a new era of bacterial chemotherapy. In a short span of twenty years the stimulus has produced important reactions in the allied field of protozoal disease and, in a broader sense of chemotherapy, in the allied fields of non-infectious disease.

By 1939 the literature of sulphonamide drugs had become enormous and the nomenclature chaotic, so that a grateful scientific world welcomed the original Northey review on sulphonamide drugs published in *Chemical Reviews*, 27, 85 (1940). The present monograph is the outgrowth of this review, revised and amplified; the new compounds now number 5,400. The system of nomenclature used in the original review and which received world-wide approval is used in the book, and is that developed by the author in collaboration with Austin M. Patterson. The general classification is a sensible compromise with Beilstein's "Handbuch der organischen Chemie".

There are twelve chapters, the first seven of which describe the nomenclature, classification and synthesis of sulphanilamide derivatives, related derivatives and sulphones. Chapter 8 is by Dr. H. J. White, of the bacteriological department of the Stamford Research Laboratories, and deals capably with the 'standard methods' and their pitfalls. There is a sound helpful chapter (10), by Dr. J. T. Litchfield, on the pharmacology, with special emphasis on absorption and distribution and which reflects, almost audibly, the teachings of the master, E. K. Marshall. There is also a comprehensive clinical survey by Dr. B. W. Carey, of the Lederle Laboratories Division. Chapter 11 is devoted to an unusually complete survey of the theories of the mechanism of action of sulphonamide drugs. The author has some sound and pleasing general observations, and he notes "that all theories are at best mere abstractions from reality which are approximately true under special conditions", and "new fundamental discoveries in the field are usually made by men able to think outside of the prevailing theories, or astute enough to recognize phenomena not conforming to the theories".

The formidable task of reducing to orderly dimensions the very heterogeneous collection of sulphanilamide derivatives and related sulphones is extremely well done. Beginning with a clear and logical nomenclature, some thousands of derivatives are listed and classified, the various categories being tabulated in the table of contents and the index. Having mastered the (simple) rules of Chapter 2, the reviewer made several trial excursions and emerged, to his satisfaction, with the compound sought. A random sample (2 per cent) of the 2,668 references quoted found meticulous accuracy.

The book is well printed on good paper, but the tables are indifferently set; it is expensive.

GEORGE BROWNLEE

British Rainfall 1946

The Eighty-sixth Annual Volume of the British Rainfall Organisation. Report on the Distribution of Rain in Space and Time over Great Britain and Northern Ireland during the Year 1946 as recorded by about 5000 Observers. (Air Ministry: Meteorological Office, M.O.495.) Pp. v+214. (London: H.M. Stationery Office, 1948.) 21*s.* net.

"BRITISH RAINFALL" makes a welcome reappearance after a gap of six years, the latest preceding volume being that for 1939. There are some changes of format, and a number of the maps are missing; but the essential features, so necessary in planning the best use of water, remain. These include, besides the distribution of monthly, seasonal and annual rainfall and raindays, chapters on dry and wet spells, duration of rainfall, heavy falls, evaporation and percolation; all are plentifully illustrated by tables, and there are still a good many maps. It is pleasing that the coloured chart of rainfall as a percentage of normal remains. But the text is necessarily curtailed, and well over half the volume consists of the "General Table" giving the annual totals of rain and raindays, and the long-period average rainfall for about 5,000 stations.

The introduction emphasizes that such a vast fund of information is only made possible by the enthusiasm of a large body of voluntary observers, some of whom have maintained their records for many decades. The volume records the deaths of two observers—Sir John Eldon Bankes and the Mackinnon of Mackinnon—of seventy years standing, and seventeen others of more than thirty years. Unfortunately, the "General Table" lacks the records from Eire, which has now its own meteorological service. The data for 1940–45 are to be published shortly in two three-yearly volumes.

New Syllabus Algebra

By C. O. Tuckey and W. Armistead. Pp. viii+201. (Cambridge: At the University Press, 1948.) 5*s.* net; without Answers, 4*s.* 6*d.* net.

THIS is a really modern book on algebra, designed to cover those parts of the subject which are of special interest and importance. It is based largely upon the recommendations suggested in a report issued in 1944 by a representative conference of examining bodies and teachers. In this report it is stated that "The transition from static mathematics of the formula, which enables one quantity to be calculated when another is known, to the dynamic mathematics of the function, which considers how one thing changes with another, is one of the chief ways in which mathematics has adapted itself to the consideration of practical problems". As the authors point out in the preface, this course of algebra has been "arranged according to the types of function to which various processes are applied instead of the customary division according to types of manipulation". A feeling is thus created for functionality which can be developed at an early age.

The book is divided into three parts: the beginnings; proportion and linear functions; squares, areas and quadratics. The new method for factors, given on p. 142, was taught by the reviewer for many years. Its logical conciseness renders it particularly interesting to pupils, and any legitimate method which serves to stimulate interest is manifestly worth while. The method may easily be extended to include cases where the coefficient of x is other than unity. A fundamental place is given to the pupil's concept of functionality by introducing ideas of the gradient and of the derivative of quadratic functions.

The whole course is thoroughly sound and skilfully written, a special feature being the last few pages devoted to topics of algebraical interest, for these will bear out "the desire to bring mathematics more closely into relation with the life and experience of the pupil". Answers are provided, and there is a single-page index.

F. G. W. BROWN

The Essential Oils

By Dr. Ernest Guenther. Vol. 1: History, Origin in Plants, Production, Analysis. Pp. xvi+427. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1948.) 33*s.* net.

THIS collaborative work has behind it the resources and experience of Fritzsche Brothers of New York, well known as producers of essential oils. Dr. E. Guenther, a vice-president of the firm, discusses the technique of essential oil distillation, from the broadest principles of the binary distillation diagram down to such details as the effect of pressure differential within the still in liberating the oil from the plant cells. Enfleurage and solvent extraction, and the preparation of terpeneless oils, are illustrated from Messrs. Fritzsche's practice and also from that followed in Grasse and elsewhere. Mr. E. E. Langenau, director of the firm's analytical laboratories, describes in working detail the determination of the analytical characters of essential oils, and the estimation of impurities, adulterants, and constituents of particular importance such as cineole and stearoptene. A director of the American Institute of the History of Pharmacy (Dr. George Urdang) sketches the history of the industry; and a professor of bio-organic chemistry (Dr. Haagen-Smit) discusses the pure chemistry of the chain- and ring-systems encountered, and the plant physiology of their formation. The section on the functions of the oils in plants offers, perhaps, too many tentative solutions of this question for any of them to seem very satisfying; analogously to the famous theologian in meditation on the cosmos, the reader may begin to feel that he has learned every possible thing about essential oils except why God created them. The scope outlined for future volumes of the work, however, suggests that even this uncertainty will, in due time, be resolved.

Rhenium

Dvi-Manganese, the Element of Atomic Number 75. By Dr. J. G. F. Druce. Pp. viii+92. (Cambridge: At the University Press, 1948.) 10*s.* 6*d.* net.

THE discovery of rhenium in 1925 was quickly followed by widespread and intensive research on its properties, so that, within seven or eight years, sufficient information had become available to enable several authors to produce monographs on the element. Since then, a considerable amount of further knowledge has been accumulated, so that a new publication is to be welcomed. Dr. J. G. F. Druce should be well qualified to undertake this task, for he has been actively interested in rhenium throughout its history. His monograph covers the subject fairly well and provides a useful summary of the chemistry of the metal and its compounds. Unfortunately, however, it gives the impression of having been hurriedly written. For example, on page 14 a description is given of the systems tungsten–rhenium and phosphorus–rhenium, and this is again repeated on page 66. Furthermore, in describing potassium perrhenate the statement is made (p. 40), "Its density is about

4·89. In toluene, however, Biltz found the value 11·4." This latter value is obviously incorrect and, indeed, has nothing to do with potassium perrhenate, but is, actually, the density of rhenium dioxide. Then again, on page 16, a table is given of the principal lines in the optical spectrum of the element, which is stated to be "by Loring", whereas it is due to W. F. Meggers and is merely quoted by Loring in an article.

At the end of the text there is given a chronological bibliography which the author claims to be complete and to have been compiled with great care. It is, however, not complete and even omits one or two references which have been mentioned in the text. Moreover, the reviewer found at least a dozen errors of one kind or another in it. Nevertheless, the bibliography is very useful and is reasonably complete, particularly with regard to papers dealing with the chemistry of the metal and its compounds. G. R. DAVIES

The Students Handbook to Foundations of Animal Feeding

By L. T. Lowe. Edited by G. H. Purvis. (Published for the Monmouthshire Institute of Agriculture.) Pp. 93. (Worcester: Littlebury and Co., Ltd., 1948.) 8*s*. 6*d*. net.

THIS small book, according to its dust-cover, purports "to provide as concisely as possible essential modern technical and scientific information for those engaged in training and advising agricultural students of all kinds, and especially those at agricultural and horticultural institutes", in which activities author and editor have considerable experience. Unfortunately this reviewer holds the opinion that clarity is preferable to conciseness and repetition, and that punctuation and careful proof correction are essential in even the most elementary scientific texts. Moreover, he also doubts whether acquisition of a patter reflects a thorough appreciation of principles. For these reasons he finds this compilation disappointing. Even if the purpose were to provide only a handy reference, little is gained by adding an eight-page glossary which mainly repeats or paraphrases explanations in the seventy-page text, or by separating "Index, Animal Nutrition" from "Index, Feeding Stuffs". J. E. NICHOLS

Your Body and the Way it Works

By Prof. Winifred Cullis. (Understanding the Modern World Series.) Pp. 32. (London: George Allen and Unwin, Ltd., n.d.) 3*s*. 6*d*. net.

IN her broadcasts to schools and lectures to members of the Armed Forces, as well as in instructional films, Prof. Winifred Cullis has gained an enviable reputation as a popular interpreter of human physiology. In her latest little book she adds to that reputation by successful collaboration with Ian Morrison, an accomplished artist who has also had experience of teaching physiology to young people in school. As in other books in this series, the author expresses herself largely through the artist, each topic being presented visually rather than prosaically. The section dealing with the brain and nerves, for example, contains enough diagrams with suitable legends to enable the young reader to understand the general working of the human nervous system. The diagrams have been ingeniously devised and well drawn in attractive colouring, and should stimulate sufficient interest to lead the reader at once to the accompanying text, which has been clearly thought out to fit in with the diagrams. Particularly fine sections are those dealing with the special senses and reproduction, the latter containing one diagram making crystal clear a point which teachers find so difficult to convey to young students, namely, the exchanges between embryo and mother in the placental circulation where the two blood circulations do not themselves mix. The book also contains a useful supplementary section indicating practical hints of what may be done to test the statements made in other parts of the book. T. H. H.

Photographic Surveying

By Colonel B. B. Talley and Paul H. Robbins. Pp. v+223. (New York, Chicago and London: Pitman Publishing Corporation, 1945.) 24*s*. net.

THIS book has been written as an introduction to the subject for those who may be concerned with photogrammetry, either from the aspect of flying and photography or as engineers who wish to make use of it, rather than for those who wish to gather a detailed knowledge of the processes. As the authors remark in the preface, "Engineers especially find that a basic knowledge of the subject is essential for full understanding of the possibilities to which photography may be put. Especially is this true of Civil Engineers. . . . The Armed Forces have been quick to realise this as is evidenced by the inclusion of this subject as part of the basic training for members of the air forces."

In view of its purpose the book is mainly descriptive in character and is profusely illustrated. It is very readable and should be easily understood by those who wish to acquire the outlines of the subject. The treatment is from the American aspect, British practice not being mentioned, although a number of European instruments are referred to. The inclusion of more than a passing reference to multi-lens photography and its rectification is somewhat surprising, because the almost universal use of wide-angle single-camera photography has superseded it except for the assembly of three cameras—generally known as Tri-Metrogon—for reconnaissance mapping. With these reservations, the book can be thoroughly recommended to those who wish to gain a general idea of the subject. C. A. H.

Das Pflanzenkleid der Mittelmeerländer

Von Prof. Dr. M. Rikli. Three vols. Pp. 1418+200 plates. (Bern: Hans Huber, 1943, 1946 and 1948.) 122.50 Swiss francs.

VOL. 3 completes Prof. Rikli's authoritative and unique work on the Mediterranean countries, a work which, in addition to assembling a vast amount of botanical information on the region, depicts the effect upon the plant cover not only of climate, but also of the various civilizations, old and new, which have made their mark upon the Mediterranean.

The first two volumes have already been reviewed in *Nature*, 152, 117 (1943); 153, 445 (1944); and 160, 416 (1947). The third and final volume supplies an author index and a very full genera and subject index combined. The greater part of the volume, however, is occupied by a list of the pertinent literature, which comprises 3,700 titles classified according to subject, the entries under regional plant geography—a very large section—again being subdivided geographically. Further, there is a list of the author's extensive travels in the region over a period covering 1889 to 1936, lists of the plates, figures in the text and maps of plant distribution, and an index of the countries, places and civilizations treated. G. M. ROSEVEARE

PHYSICS AND CHEMISTRY OF HYDROCARBON GELS

On March 24, a Royal Society Discussion was held on the subject of the physics and chemistry of hydrocarbon gels. Interest in these systems arose in the first instance from the desire to extend the range of flame throwers in which hitherto ordinary liquid hydrocarbons had been used. It was evident at a very early stage in the investigation that a possible improvement in range could be effected if the fuel could be made thixotropic in character, or at any rate if its intrinsic viscosity could be varied over wide ranges on changing the rate of shear. Further investigation revealed the fact that another physical property or combination of properties embraced under the term 'stringiness' or 'extensibility' had also to be taken into consideration.

Since gels are two-phase systems, inquiry centred around the preparation of suitable hydrocarbon gels. The gel-forming polymeric network could be introduced into the hydrocarbon by swelling and dispersion, or could be formed *in situ* as a result of suitable chemical reaction. Of the former, the early rubber–petrol systems were soon replaced by *iso*-butylmethacrylate or by cellulose acetate in a suitable fuel solvent, whereas the aluminium soaps of fatty acids were found to be most suitable among the latter class.

A linear polymer will dissolve in a hydrocarbon if the free energy of solution ΔF is negative. A high heat of solution ΔH may counterbalance the large (for polymers) entropy ΔS of solution. If $\Delta F = \Delta H - T\,\Delta S$ is positive, complete solution does not occur, but there results a swollen gel in equilibrium with almost pure solvent.

The degree of swelling of the gel phase is determined by a solvent-polymer interaction term μ. For linear polymers, μ can be defined by

$$\Delta F = RT \log (1 - \nu) + \nu\left(1 - \frac{1}{n}\right) + \mu\nu^2,$$

where ν is the volume fraction of the polymer and n the ratio of solute/solvent molecular weight.

For a cross-linked polymer, the free-energy term must include not only the change due to dilution, but also the elastically stored free energy in the swollen network; expressions for this term, both for equilibrium strain-free and strained conditions, were described by Dr. L. R. G. Treloar.

This elastic energy may be stored as orientation entropy in the flexible chains, as potential energy in bent or stretched valency bonds or as a twist against the hindered potential opposing free rotation about the C—C axis. In the case of an isolated long-chain molecule, Kuhn showed that the force per unit extension would be inversely proportional to the number of bonds for orientation entropy and inversely proportional to the square of the number for twisting against hindered rotation.

The molecular spring in a gel is the average strand between two junction points in the framework, and the number of junction points as well as the number of strands is evidently proportional to the square of the volume concentration. The average length of a strand is, conversely, proportional to the concentration; consequently, the rigidity of the network should be proportional to the square of the volume concentration for the energy stored in the chain entropy, and to the cube of the concentration for twisting against hindered rotation. Data on the rigidity of gels as a function of the concentration of gelling polymer are scanty; but, such as they are, they suggest that twisting of the chains against hindered rotation rather than bond extension or chain entropy is the main factor involved.

It is evident that to obtain a fuller understanding of this partition of polymer between swollen gel and dilute solutions as separate phases, a close examination of the phase behaviour of polymer and solvent is desirable. Dr. A. E. Alexander gave an account of the examination of the swelling and solubility of cellulose acetate in benzene–xylenol mixtures. He has found that the solubility of the acetate in benzene–xylenol mixtures is greatly influenced by the degree of acetylation. By comparing the solubilities and swelling powers of the separated fractions in benzene–xylenol mixtures of different compositions, it has been shown that preferential adsorption of the xylenol takes place from these mixtures, and from the two sets of experiments phase diagrams have been constructed which when superimposed on one another reproduce the data obtained with the original material.

The rather complex rheological properties of these 'thickened' hydrocarbon systems were the subject of several communications, including those of Dr. A. H. Nissan, Dr. K. Weissenberg and Mr. R. S. Rivlin.

While the majority of these polymer-containing hydrocarbon systems are thixotropic in character and thus can store potential or elastic energy when distorted, they all exhibit the property of anomalous viscosity or non-Newtonian flow; indeed, the intrinsic viscosity may vary as much as a millionfold when the rate of shear is changed.

The point of thixotropic breakdown is now generally associated with a balance being achieved between the rate of cross-linking or bond formation and bond breaking, and it is evident that if these can be regarded as independent rate processes, the anomaly in the viscosity shear curves can readily be interpreted. Attempts have also been made to apply the considerations advanced by Eyring to these systems; but the physical interpretation of the actual mechanics of the processes involved on this basis is by no means clear. One of the most interesting conclusions arrived at from theoretical argument is the fact that to describe the flow properties of these solutions, two, and not one, physical parameters are required. If viscosity be chosen as one of them, the other is a normal stress coefficient. In a steady state of flow the normal stress coefficient may not vanish and will give rise to many of the effects which these anomalous liquids exhibit.

A great deal of attention has been devoted to the aluminium soaps as gelling agents for hydrocarbon fuels, and communications on this subject were made by Dr. A. E. Alexander, Dr. G. A. Parry and Dr. J. H. Schulman. Aluminium exhibits six-fold co-ordination and is amphoteric in its salts. The simplest compounds may be regarded as derivatives of $[\mathrm{Al}(\mathrm{OH})_6{}''']\,\overset{+}{\mathrm{H}}_3$ (aluminic acid) and $[(\mathrm{H_2O})_6 \rightarrow \overset{+++}{\mathrm{Al}}]\,\mathrm{Cl}_3$ respectively. Salts of the type $[(\mathrm{H_2O})_5\ \mathrm{Al}\ \overset{++}{R}]\ \overset{-}{R}_2$ can evidently be prepared.

Bjerrum and Stiasny were the first to examine the condensation of these substances by the elimination of water by processes they termed 'olation' and 'oxolation', and condensation polymers up to the tetramer can readily be identified.

For the purposes of gelation, the anhydrous aluminium soaps are most readily prepared by reaction of the aluminium alkoxides formed by direct interaction of the metal with the alcohol and fatty acids in an organic solvent, although similar results can be obtained from freshly precipitated aluminium hydroxide and the free fatty acids, or by ordinary metathesis between an alkali metal soap and an aluminium salt.

There still appears to be a certain amount of doubt in respect to the nature of the soaps of aluminium. The existence of di-acid soaps, $Al(OH)L_2$ and $Al(OR)L_2$, where L is the acid radical, is well established both by Karl Fischer's method for water determination and also calorimetrically from the heats of neutralization. Neither the tri- nor mono-soap appears to be readily prepared, at least from aqueous solutions, the product consisting mainly of the di-soap with adsorbed free fatty acid or hydrated alumina.

The complexes formed in strong solutions can be broken down by means of peptizing agents. Their mode of action can be ascribed to the breaking of the aluminium oxygen co-ordinate links by preferential co-ordination with the peptizer, and thus a large variety of compounds, such as water, amines, pyridine, alcohols, and, after that, phenols and fatty acids, can serve as peptizers.

ERIC K. RIDEAL

VARIABLE AND CONSTANT COMPONENTS OF CHROMOSOMES

By DR. A. E. MIRSKY and HANS RIS
Rockefeller Institute for Medical Research, New York

A STUDY of isolated chromosomes has shown that they contain desoxyribonucleic acid, histone and another protein of an entirely different character from a histone[1]. This protein remains as a microscopic fibre after extraction of desoxyribonucleic acid and histone from the chromosome. The coiled thread that is left after removing desoxyribonucleic acid and histone is called a 'residual chromosome', and the protein of the thread is referred to as the 'residual protein' of the chromosome. Some ribonucleic acid is combined with residual protein. The thread of residual protein is the basis for the thread-like structure of the chromosome. In the isolated chromosomes that were first prepared, those of nucleated erythrocytes of the carp and of calf thymus, the residual protein represented only 4 and 8·5 per cent respectively of the dried mass of the total chromosome, the remainder of the lipid-extracted chromosome being almost entirely nucleohistone.

Isolated chromosomes have now been prepared from beef liver, kidney and pancreas. For this purpose it was necessary to add several steps to the original procedure, for otherwise the chromosomes obtained were contaminated with considerable quantities of non-chromosomal material. In a suspension of isolated chromosomes, morphologically different individuals can be identified, and the same chromosomes are found in preparations from thymus, liver, kidney and pancreas of the same organism. This recognition of chromosome individuality in preparations of isolated chromosomes from different tissues is especially striking when the chromosome is the one to which a nucleolus is attached.

Fractionation of liver, kidney and pancreas chromosomes shows (figures given in Table 1) that their composition differs markedly from that of erythrocyte and thymus chromosomes, in that the former contain less nucleic acid and far more residual protein.

The composition of a chromosome appears to be related to the nucleo-cytoplasmic ratio of the cell in which it is located. Thymus lymphocytes have only a scanty cytoplasm compared with the abundant cytoplasm present in most cells of the liver, kidney and pancreas. We find that the nucleus represents 60 per cent of the mass of thymus cells and only 10–18 per cent of the mass of cells of the liver, kidney and pancreas. Chromosomes of nucleated erythrocytes, as seen in Table 1, have a composition that would be expected if they were in a cell with scanty cytoplasm. They have, in fact, a large cytoplasm, but one that is relatively inert metabolically. This shows that what is significant in the relationship between nucleo-cytoplasmic ratio and chromosome composition is the metabolic activity of the cytoplasm, as well as its bulk. Further evidence may be cited relating chromosome composition to nucleo-cytoplasmic ratio of the cell. The lymphocytes in the lymph nodes of beef contain far more cytoplasm than do the lymphocytes of calf thymus; and, in accordance with the rule that has just been mentioned, the nuclear substance of lymph node lymphocytes has a much lower percentage of desoxyribonucleic acid. The nucleo-cytoplasmic ratio of liver cells changes considerably when an animal fasts. In fasting, there is a decrease in the ratio of cytoplasm to nucleus. In these circumstances we would expect to find the percentage of desoxyribonucleic acid in the nuclear substance of liver cells to increase during fasting—and analysis does, indeed, show this.

Table 1

Chromosomes of:	Desoxyribonucleic acid (per cent)	Residual protein (per cent)
Carp erythrocyte	41	4
Calf thymus	39	8·5
Calf liver	26	39
Calf kidney	28	33
Beef pancreas	28	29

From the data given in Table 1 it cannot be said whether the differences in percentage composition of chromosomes of different cells of the same organism are due to variations in the quantity of nucleic acid or in the quantity of residual protein present in a given chromosome. When cytologists observe differences in staining of chromosomes, they frequently conclude that more or less chromatin is present in the chromosomes. The material in the chromosome that stains (chromatin) is desoxyribonucleic acid, and in the cytological literature there are many statements, based on staining, concerning an alleged increase or decrease in quantity of desoxyribonucleic acid in chromosomes. What is actually being observed is a change in percentage composition. An apparent decrease in quantity of nucleic acid (chromatin) may be simply a decrease in the percentage of nucleic acid due to an increase in quantity of residual protein in the chromosome, the actual quantity of nucleic acid in the chromosome possibly remaining constant.

The quantity of nucleic acid in a single nucleus can be determined if the number of nuclei can be counted in a given mass of material used for analysis. For some cells, those of liver, for example, this is readily accomplished by isolating a mass of nuclei using the citric acid method and counting the number in a given volume of the suspension. In other cases, erythrocytes and sperm, the cells themselves can be counted. A comparison of the desoxyribonucleic acid contents of the nuclei of the erythrocyte and liver cell of the domestic fowl is of interest. Analysis of dried liver nuclei shows that 21·8 per cent is desoxyribonucleic acid, whereas of the dried erythrocyte nuclei 40·4 per cent is desoxyribonucleic acid. Despite this difference, the *quantities* of desoxyribonucleic acid per nucleus are found to be identical for these two nuclei. The analytical figures for the fowl, a number of fish, the frog, toad and turtle are given in Table 2. The quantity of desoxyribonucleic acid is a constant for different cells of the same animal, and the value of this constant is a characteristic of each species.

Table 2

	Desoxyribonucleic acid (mgm. × 10^{-9}) in:			
Animal	Nucleus of erythrocyte	Nucleus of hepatic cells	Sperm	Number in previous column × 2
Domestic fowl	2·34	2·39	1·26	2·52
Shad	1·97	2·01	0·91	1·82
Carp	3·49	3·33	1·64	3·3
Brown trout	5·79		2·67	5·34
Frog	15·0	15·7		
Toad	7·33		3·70	7·40
Green turtle	5·27	5·12		

Different as erythrocytes and liver cells are from each other, one point of identity is that they have the same number of chromosomes, and it is surely significant that desoxyribonucleic acid is found in the chromosomes only. Because of these considerations, and because sperm cells have one half the number of chromosomes found in somatic cells, the quantities of desoxyribonucleic acid per sperm cell were determined for various species. From the results given in Table 2, it can be seen that the quantity per sperm cell is one half that found in a somatic cell. Observations on egg nuclei show that the quantity of desoxyribonucleic acid in the egg nucleus corresponds very closely to that in the sperm. If the data given in Table 2 are considered in relation to the chromosome theory of heredity, the conclusion that follows is that desoxyribonucleic acid is part of the genic material. This does not mean, however, that the gene consists of nothing but nucleic acid.

Since the quantity of desoxyribonucleic acid per nucleus is a constant for a species, it has been determined by us for a considerable number of animals, invertebrates and vertebrates. These values are of interest from an evolutionary point of view.

Once it is known that the quantity of desoxyribonucleic acid per nucleus is the same in different cells of an organism, it becomes clear that the quantity of residual protein varies considerably. A cell with an abundant, metabolically active cytoplasm has chromosomes with a large quantity of residual protein; and a cell with scanty cytoplasm has chromosomes with but little residual protein. The residual protein of the chromosome, it would seem, is concerned with interactions between chromosome and cytoplasm. Since the needs of the cytoplasm vary in different cells, and vary in a given cell at different times, it is scarcely surprising that the residual protein is, at least in part, a variable component of the chromosome.

Table 3

Nucleus of:	Desoxyribonucleic acid in 1 nucleus × 10^{-9}	Multiple of value found in sperm
Bull sperm	2·82	
Calf thymus	7·15	2·54
Calf lymph node	7·03	2·49
Calf kidney	6·25	2·21
Beef kidney	6·81	2·41
Calf liver	6·22	2·20
Beef liver	8·4	3·0

In Table 2 no values for mammals are given. Table 3 contains some analytical values for the nuclei of cattle. It will be seen that there are some variations from the simple relationships found in other vertebrates. It is well known that polyploidy occurs in mammalian liver, but polyploidy is not the explanation of the high value found for beef liver, for in counting liver nuclei the double-size nuclei were counted separately and the necessary correction was made. It is probable that some other duplication of genic material is responsible for the analytical results given in Table 3.

Finally, it should be mentioned that Boivin[2] and his collaborators have made determinations of the quantity of desoxyribonucleic acid per nucleus in several mammals. Their work and ours have been done altogether independently of each other. A comparison of the analytical values shows that some of their results differ from ours.

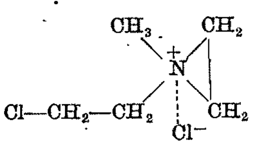
MODE OF PRODUCTION OF CHROMOSOME ABNORMALITIES BY THE NITROGEN MUSTARDS

THE POSSIBLE ROLE OF CROSS-LINKING

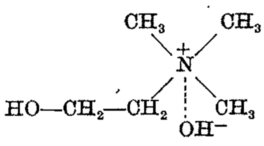
By R. J. GOLDACRE, A. LOVELESS
AND
W. C. J. ROSS
Chester Beatty Research Institute, The Royal Cancer Hospital, London, S.W.3

In a recent publication[1] attention was directed to the cytotoxic action of a series of halogenoalkylarylamines, of which the compound $PhN(CH_2CH_2Cl)_2$ may be taken as typical. The structural conditions requisite for activity were stated to be the presence of two halogenoalkyl groups in the molecule together with a certain minimum reactivity of the halogen, as measured by the ease of hydrolysis. In the cytological changes which these compounds produce they largely resemble their aliphatic analogues.

The action of the nitrogen mustards has been connected with their ability to pass into a cyclic ethyleneimonium ion (I)[2]. This ion presents a formal resemblance to choline (II), as pointed out by Barron, Bartlett and Miller[3], and these authors have found that the aliphatic nitrogen mustards are antagonists for choline oxidase, acetylcholine-esterase and choline-acetylase :



(I)



(II)

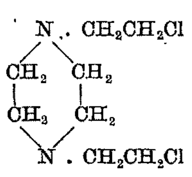
While formation of a cyclic ion may also occur in otherwise inactive compounds with only one halogenoalkyl side-chain, the presence of a second side-chain obviously permits a much closer analogy with choline, and might conceivably be significant in this way. In a recent paper[4] it is, however, shown that there is no evidence for the formation of a cyclic ion from the aromatic nitrogen mustards, while the possibility of the transitory existence of such an ion cannot, of course, be completely excluded. The evidence against the existence of a cyclic ion is, briefly, as follows : (1) the amount of halide ion liberated is at all times equal to the acidity produced, and it can be assumed that no quaternization of the nitrogen atom occurs ; (2) the instantaneous reaction with thiosulphate, which has been used as a measure of the concentration of the cyclic ion, is not observed with these compounds ; (3) although S. D. Ross has shown[5] that 1-diethylamino-2-chloropropane undergoes a rearrangement on hydrolysis which is interpreted as involving the closing of the ethyleneimonium ion followed by re-opening of the ring at a different point, the analogous aromatic compounds have not been found to undergo such a change.

It has already been suggested that the cytotoxic activity of the nitrogen mustards may be due to the alkylating effect of the halogenoalkyl group on functional groups of body constituents. Thus the active aliphatic compounds react with amino, sulphydryl, carboxyl and imidazole groups in proteins[6] and almost certainly with amino and secondary phosphoryl groups in nucleic acids, as has been found for di(chloroethyl) sulphide, one molecule of which may react with two groups[7]. Now there is considerable evidence[8,9,10] that groups such as these in the protein molecule are not always accessible, but are at some time buried within the molecule, owing to a change in the folding of the polypeptide chain, which is held by Astbury[11] and Seifriz[12] to be the basis of protoplasmic contractility in general. In particular, it is suggested that the shortening of prophase chromosomes is a continuation of the shortening by molecular folding of the chromosome's constituent fibres, which must at some stage in the resting nucleus be completely unfolded to ensure that all parts of the template contribute to re-duplication.

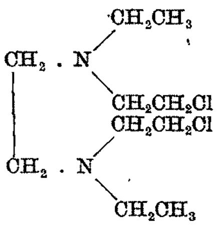
Apart from the possible implication contained in the paper by Barron *et al.*[3], no explanation has so far been given of the necessity for two halogenoalkyl groups in a single molecule. A fresh possibility is now suggested, namely, that the two groups are required to permit the molecule to react at two distinct points, lying either on a single surface or fibre or, more especially, on two contiguous fibres. Thus, when the first haloalkylamino group has become anchored to a reactive centre, the second group approaches and can react with another centre either on the same protein chain or on an adjacent one. The possibility that cross-linking may play a part in the action of mustard gas on the nucleic acids has already been considered by Elmore *et al.*[7], in an investigation which these authors believed might provide an explanation of the cytological effects of mustard gas as described by Koller[13], Robson[14] and Fell and Allsopp[15].

Of the various possibilities, cross-linkage between separate fibres is of particular interest when considered in the light of the assumption that reaction is directly with the genetic material. The latter has already been postulated in respect of chemical mutagenesis[16], while it is known that the cell is most susceptible to the effects of the mustards immediately prior to mitosis when the chromosome has just re-duplicated[17]. There is therefore at this time a system in the cell consisting of parallel identical fibres, the gene strings of the sister chromatids. Moreover, the fibres are extended in the process of re-duplication and could be, by analogy with stretched elastic polymers, at their highest energy : it is not difficult to visualize breakage of chromatids or of whole chromosomes as the direct consequence of interchromatid cross-linkage at this time (for example, fragmentation could result from tension upon the extended threads of the interphase chromosomes cross-linked so as to produce a junction stronger than the fibres themselves). Furthermore, the possible uniqueness of such a system in the cell would account for the high degree of specificity of action shown by compounds of this type. The cytological changes due to the mustards are remarkably similar to those observed after treatment by X-radiation[18], and in the latter case equally it would appear worthy of investigation whether the effects are due to cross-linkage between adjacent protein chains. Such a union could arise, for example, by the interaction of two —SH groups under the oxidative influence of X-radiation which is known to occur *in vitro*.

Consideration of the above principles has suggested that many other molecular types, containing two or more groupings capable of similar reaction with functional centres in biological systems, would be effective as cytotoxic agents. Examples are already known of active compounds in which the two requisite haloethyl groups are attached to different nitrogen atoms (for example, III, IV), and it is obvious that a great number of variants, especially involving heterocyclic types and modification of the side-chains, calls for investigation : work along these lines is proceeding, as also upon the possible antagonistic action of thiols, and will be reported later.



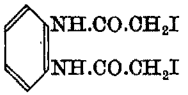
(III)



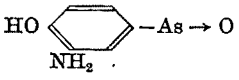
(IV)

One compound of this type upon which preliminary tests have been made is di(iodoacetyl)1 : 2-phenylenediamine (V). In tests on larvæ of *Triturus palmatus* typical radiation effects were produced in epithelial cells, fragment formation and anaphase bridges both with and without accompanying fragments being observed. The compound 'Mapharside', 3-amino-4-hydroxyphenylarsenoxide (VI), which can undergo a reversible condensation reaction with a pair of —SH groups[19], has also been tested in the same manner.

In this case the effect was to produce 'stickiness' after a few hours, and at periods of 24–48 hours after treatment, anaphase bridges with and without accompanying fragments: no fragmentation was observed except in association with bridges.



(V)



(VI)

The above suggestions as to the mechanism of action of the nitrogen mustards are put forward purely as a working hypothesis, and as possibly the simplest of a number of alternative explanations consistent with the chemical and cytological data. If, however, it is indeed true that chemical substances of these kinds produce some of their characteristic effects by reacting directly with the uncoiled resting chromosomes in the manner described, a new approach will become available to the related problems of growth inhibition, induced mutation and carcinogenesis. The connexion between these phenomena is now receiving further emphasis from the fact that tumour induction by the nitrogen mustards has recently been achieved both in the aliphatic series[20], and in the aromatic series[21]. Further reports upon this last subject will be published elsewhere.

The authors wish to express their indebtedness to Prof. A. Haddow for much advice and encouragement. The investigation upon which this discussion is based has been supported by grants made to the Chester Beatty Research Institute by the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the Division of Research Grants of the U.S. Public Health Service, and is being conducted during the tenure by one of the authors (W. C. J. R.) of a Sir Halley Stewart Fellowship, and by another (R. J. G.) of a grant from the Forsyth Bequest of the Royal Society.

OBITUARIES

Sir Thomas Hill Easterfield, K.B.E.

Sir Thomas Hill Easterfield died at Nelson, New Zealand, on March 1, aged eighty-three, and on March 18 his ashes were scattered in a garden nook at the Cawthron Institute. He was born at Doncaster, Yorkshire, in 1866, received his primary education at the Doncaster Grammar School, and later entered the Yorkshire College (now University of Leeds), where he won a scholarship in geology and gained his first insight into chemical research, which inspired his life-work. From Leeds he proceeded to Cambridge as a foundation scholar of Clare College and gained first-class honours in the Natural Sciences Tripos; this was followed by studies at the Zurich Polytechnic School and at Würzburg. In 1888 he returned to Cambridge as a junior demonstrator in the University Chemical Laboratory, becoming a University extension lecturer in 1891, and in 1894 lecturer on pharmaceutical chemistry and chemistry of sanitary science; he was also a master at the Perse School.

In 1899 Easterfield was appointed one of the four foundation professors of the Victoria University College, Wellington, New Zealand. He held the dual chair of chemistry and physics until 1909, continuing as professor of chemistry until 1920, when he became the first director of the Cawthron Institute, Nelson, from which position he retired in 1933 after a full and active professional career. In 1938 he was honoured by knighthood in recognition of his outstanding services.

Apart from his scholastic attainments, Easterfield was a Cambridge 'miler' and took an active part in athletics. Further, as a churchman he was imbued with, and practised, the principles of Christianity which moulded his outlook and guided his footsteps. Such was this distinguished citizen who carried with him a strong sense of justice, a keenly developed flair for research, and the experienced technique of an able teacher, all of which traits left their mark on the many who had the good fortune to come under his influence.

Though Sir Thomas Easterfield will ever be remembered as an outstanding chemist who created from virtually nothing—much of the equipment was of his own making—the Department of Chemistry at Victoria College, Wellington, successfully fathering such an undertaking through all vicissitudes, it must be stressed that his scientific horizon was by no means limited by chemistry; he possessed a wide understanding of both physical and biological sciences. He held the unshakable belief that fundamental research is the prime factor in scientific advancement; he held an equally strong belief in the necessity for the application of science. It was this broad and tolerant outlook which so fitted him to direct, from their infancy, those physical and biological researches, both fundamental and technical, which, through his foresight and ability, caused the Cawthron Institute to develop so rapidly to a high standing among research organisations.

David Miller

Mr. G. M. Mathews

Gregory Macalister Mathews, author of "Birds of Australia", died at Winchester after a short illness on March 27. He was the son of R. H. Mathews, a well-known authority on Australian aborigines, and was born at Biamble, New South Wales, on September 10, 1876. After attending King's School, Parramatta, he worked on a cattle station in north Queensland and spent much of his spare time studying birds. He amassed a large collection, supplemented by many specimens received from correspondents all over Australia. For long he had planned to write a work on Australian birds, and in 1902 went to England for the purpose. At first he resided near Watford, which was convenient for the British Museum (Natural History) and Lord Rothschild's museum at Tring, where much of his work was done.

As a preliminary to his larger work, he published in the *Emu* during 1908 a "Handlist of the Birds of Australia"; then in 1912 the "Birds of Australia" began to appear, and this was finally completed in 1927 in twelve thick folio volumes. His next work was a check list of the birds of Australia and the Polynesian region, entitled "A Systema Avium Australasianarum", brought out under the auspices of the British Ornithologists' Union. Mathews had long been interested in two small islands lying between Australia and New Zealand, and in 1928 he published an account of the birds entitled "Birds of Norfolk and Lord Howe Islands", followed eight years later by a supplement.

In his earlier works he was an extreme 'splitter', and a large number of his races are not now recognized. In genera, too, he went to the same extreme, and this to a great extent was due to his confining his studies to Australian species only. In recent years, however, he greatly modified his views. He was greatly interested in nomenclature and the study of early writers on Australian birds, and his best work was done in this connexion. Between 1912 and 1927 he edited a magazine of his own, *Austral Avian Record*, which contained much useful information. But by far the most important of his publications was the "Bibliography of the Birds of Australia", which appeared in 1925 as a supplementary volume to "Birds of Australia". This is more than a bibliography, and might be considered the foundation for a history of the study of birds in Australia.

Mathews was a great collector of books and amassed the finest collection of works dealing with Australian birds. This he presented to the Australian Government in 1929, and it is now housed in the National Library in Canberra as the Mathews Ornithological Library. His collection of birds passed into the hands of the late Lord Rothschild and is now in the American Museum of Natural History in New York.

Mathews was a keen sportsman, interested in both hunting and shooting, and while engaged in his ornithological studies travelled widely, visiting most of the more important museums both in Europe and the United States. In 1924 he was vice-president of the British Ornithologists' Union and during 1936–38 was chairman of the British Ornithologists' Club. He married Marian, daughter of H. C. White, of Mudgee, New South Wales, who died in 1938, and is survived by a son.

N. B. K.

NEWS and VIEWS

Zoology at King's College, London: Dr. J. F. Danielli

Dr. Danielli, who is succeeding Prof. Mackinnon as professor of zoology in King's College, London, commenced research work in 1931 at University College under the direction of Prof. N. K. Adam. He was then working on monolayers of steroids and on cell permeability. In 1933 he went to Princeton University with a Commonwealth Foundation Fellowship and continued his work under the influence of Prof. E. N. Harvey and Prof. C. G. Conklin. He returned to University College, London, under the auspices of Sir Jack Drummond and Prof. A. V. Hill. From University College he went to Cambridge in 1938, with a Beit Memorial Medical Research Fellowship tenable in the Department of Biochemistry. Here his work was extended to the blood capillaries. He became a member of a Ministry of Supply extra-mural chemical defence research team and a fellow of St. John's College in 1942. During his later years in Cambridge he was attached to both the Departments of Zoology and Biochemistry, and his main attention was turned to cytochemistry. In 1946 he went to the laboratory of the Marine Biological Association as physiologist, and then became reader in cell physiology of the University of London at the Chester Beatty Research Institute of the Royal Cancer Hospital, and also honorary lecturer in pharmacology at University College. He plans to continue the programme developed at the Royal Cancer Hospital, and to develop research work in cytology particularly in collaboration with Prof. T. A. Bennet Clark and Prof. J. T. Randall.

Geography at Cambridge: Mr. J. A. Steers

Mr. J. A. Steers, who, in September, is to succeed Prof. F. Debenham as professor of geography in the University of Cambridge, was one of the first generation of geographers to take the newly constituted Geographical Tripos after the First World War. After a short spell of teaching at Framlingham, Mr. Steers returned to Cambridge to join the staff of the Geographical Department under Philip Lake. His College elected him to a fellowship, and before many years St. Catharine's became the first men's college to offer scholarships in geography. This led to a remarkable concentration of able geographical students in the College, which has resulted in a rapidly lengthening list of St. Catharine's geographers entering university posts—fifteen in the last ten years. In his College, Mr. Steers has served successively as dean, tutor, senior tutor, and president.

The Norfolk coast was the scene of Mr. Steers's early researches, and his frequent visits led to Norfolk replacing his own native Bedfordshire as his favourite county. These activities centred mainly on Scolt Head Island, where for many years parties of Cambridge men mixed the more sober academic pursuits with strenuous bursts of bathing and creek jumping. His taste for coastal problems led him to other parts of Britain, and culminated in two expeditions to the Great Barrier Reefs of Queensland, and one to Jamaica. A succession of papers followed promptly on various aspects of the physiography of coral reefs —the main work of writing up was sometimes accomplished on board the ship while returning to England. During the Second World War his love of the coastline led him to turn his attention to the preservation of its amenities, and his major publication, "The Coastline of England and Wales", was intended to serve the double purpose of summarizing the state of our knowledge of the coastline and of focusing attention on the need for preserving this ample but easily marred heritage. He has completed a report on the English and Welsh coasts for the Minister of Town and Country Planning, and is now engaged on a similar project for the Scottish Office. Mr. Steers's interests have by no means been confined to the coastline. His first book, "Map Projections", was a surprising and most adequate production for one who lays no claim to mathematical knowledge. "The Unstable Earth" is more representative of his real interests, which have always been close to geology; but perhaps "Scolt Head Island" expresses most nearly his approach to problems, in that it brings together the work of specialists on the various field studies in the elucidation of one specific region.

Hosiery Research Council: Dr. D. Starkie

Dr. David Starkie has been appointed director of research by the Hosiery Research Council. The appointment is one of the most important preliminary steps yet taken in the establishment of a research organisation for the hosiery industry. Dr. Starkie, who is forty-four, was educated at Staveley Grammar School and the University of Sheffield, and obtained a degree in physics, with first-class honours, in 1925. He was awarded his M.Sc. in 1926 and Ph.D. in 1927 as a result of work on the band spectra of the alkali compounds. After leaving the University, Dr. Starkie lectured and carried out research on the physical properties of glass. He spent two years on research with the Metropolitan-Vickers Electrical Co., Ltd., and then became chief physicist at Messrs. A. Jobling and Co., Ltd., glass manufacturers. In 1939 Dr. Starkie was appointed head of the physics research department of the Plastics Section of Imperial Chemical Industries. Much of his time was devoted to the investigation of the properties of synthetic yarns and fibres, and he worked in close collaboration with a special fibres development department formed to develop the use of synthetic fibres in the textile industry. When it was decided to create an optical development department in 1944, Dr. Starkie was placed in charge of its formation, and the results of his work have had important effects in the optical field. Dr. Starkie is a member of a number of scientific societies and service committees and is also on the Council of the British Scientific Instrument Research Association. He will be responsible for the plan and organisation of the new Hosiery and Allied Trades Research Association now being formed. The Hosiery Research Council, which has done the preliminary work, already possesses premises equipped for research at Thorneywood House, Nottingham, where there is the nucleus of a trained staff.

Rumford Medals: Dr. I. S. Bowen

The Rumford Medals for 1949 of the American Academy of Arts and Sciences, given for the most important discoveries in the fields of heat and light, have been awarded to Ira S. Bowen, director of the Mount Wilson and Palomar Observatories in California. It was Bowen's early laboratory study of high-excitation spectra which laid the foundations for his brilliant work on the identification of the 'nebulium' lines in the spectra of galactic nebulæ as forbidden transitions in doubly ionized oxygen. Later, his analysis of the spectra of planetary nebulæ brought to light the unexpectedly high cosmic abundance of the inert gases. The puzzle of the selective excitation of certain permitted lines in nebular spectra was explained by him in a completely satisfactory way in terms of close chance coincidences between the wave-lengths of emission lines in the inaccessible ultra-violet. Dr. Bowen is well known also as an optical designer. Perhaps the most useful device associated with his name is the 'image slicer', by which the starlight that would otherwise be wasted on the slit-jaws of an astronomical spectrograph is directed into the instrument, thus greatly increasing its effective speed. He is now in charge of the installation of the new 200-in. reflector at Mount Palomar, and is credited with a number of devices used in the optical tests. His many friends look forward with confidence to the successful initiation of the new telescope under his direction.

The Palæobotanical Society and Institute of Palæobotany, Lucknow

On April 3, the Hon. Pandit Nehru, Prime Minister of India and Minister for Scientific Research, laid the foundation stone of the newly formed Institute of Palæobotany in Lucknow. This Institute has come about as the result of a resolution passed on September 10, 1946, by the governing body of the Palæobotanical Society which had just previously been founded. The president of the Society is Mrs. Savitri (Birbal) Sahni, and the secretary, Prof. Birbal Sahni, professor of botany in the University of Lucknow.

Both Society and Institute have clearly come into being as a result of the enthusiasm of Prof. Sahni, who himself is one of the world's leading palæobotanists, and the keen interest of his wife. On the schedule of the Palæobotanical Society are Prof. Sahni's collections of scientific literature and fossil specimens; funds up to Rs. 100,000 given by Prof. and Mrs. Sahni for the building of the Institute; a perpetual endowment of Rs. 1,000 in 3½ per cent Government paper, presented by Pandit L. D. Pant for the Chandra Datt Pant Commemoration; two scholarships, furniture and laboratory equipment given by the Burmah Oil Company. It is also interesting to note that after the death of Prof. and Mrs. Sahni, all their assets are to go to the Society and Institute. Pending the completion of its own building, the work of the new Institute of Palæobotany is being carried out in a building (given to the Society by the Government of the United Provinces) by the director (Prof. B. Sahni), assistant director (S. R. Narayan Rao), curator (J. Hsü), research fellow (R. V. Sitholey), research assistants (R. N. Lakhanpol and D. C. Bhardwaj) and registrar (B. R. Agarwala). K. R. Surange has also recently joined the staff.

Commonwealth Scientific and Industrial Research Organisation, Australia

The Australian Government in March repealed the Science and Industry Research Act of the Bruce-Page Government of 1926, replacing it and its subsequent minor amendments by a single Act modifying several of the main features of the original legislation. From the Council for Scientific and Industrial Research, which has functioned for twenty-three years, all former powers and functions have been taken away, and it becomes for the future merely advisory. A new body has been set up under the title Commonwealth Scientific and Industrial Research Organisation. It consists of an Executive of five members and of the officers comprising the staff. The Executive is the governing body. Its members will be appointed by the Governor-General, and at least three of them are to possess scientific qualifications. The chairman and two others will devote the whole of their time to the duties of office. Whereas the former Council carried sole responsibility for the scientific programme placed before the Government, provision is now made for political initiation of work, it being the duty of the Organisation to exercise its powers and functions in relation to any matter referred to it by its minister. In the important matter of staff, while the Executive may appoint such officers and employ such temporary or casual employees as it thinks necessary for the purposes of the Act, it is in each case subject to the specific direction that "the selection of persons . . . shall be made in accordance with such requirements as the Public Service Board determines". So, too, terms and conditions are in all cases "subject to the approval of the Public Service Board". Also, the maximum number of officers and employees whose duties are primarily of an administrative or clerical nature is similarly subject to the Board's approval. Under the earlier Act, the Council and minister settled these matters, independently of the Public Service Board. A somewhat cryptic clause towards the end of the Act runs : "A member of the Executive, a member of the Advisory Council, a member of a State Committee, an officer or an employee shall not, except in the course of his duty as such a member, officer or employee or with the approval of the Executive, disclose any information concerning the work of the Organisation or the contents of any document in the possession of the Organisation. Penalty : Imprisonment for two years." The opportunity has been taken also to effect certain minor changes which experience has shown to be desirable ; but it is difficult at this stage to predict just how the new legislation as a whole will affect established scientific activities. The sequel need not be unsatisfactory; but it is known that in some quarters the position is regarded with a measure of anxiety.

Progress in Education

IN his presidential address to the National Union of Teachers at Margate on April 16, Mr. I. Gwynne Rees, of Port Talbot, outlined the extent to which the 1944 Education Act has already been implemented. Two years ago, at a time of unprecedented difficulties, school life for every pupil in Britain was extended to the age of fifteen. The number of teachers in primary and secondary schools is now 10 per cent greater than before the War, while the average number of pupils per teacher in the primary and secondary schools has been reduced by about 6 per cent ; in the primary school, however, the average class still remains nearly 50 per cent larger than in the secondary school. These reforms, said Mr. Rees, have been made possible by the rapid increase in the supply of well-qualified teachers, provision having already been made for the training of 66 per cent more students in the permanent colleges and 44 per cent more in the universities than before the War. The other major reform necessary for the reduction in the size of classes is, he said, the provision of sufficient classrooms. In 1948 work in progress involved an ultimate capital expenditure of £23,000,000, and in 1949 the figure would be £55,000,000. There has also been remarkable progress in the facilities for higher education. The toll-gate of school fees has been removed, and State scholarships and local education authority awards for further education have doubled in number since 1939. In the earlier stages of education, particular concern is being felt for the infant and junior schools, where the handicapping of the less gifted begins through lack of suitable equipment and through classes of forty, fifty and even sixty children. This seventy-fourth Conference of the National Union of Teachers was distinguished, for the first time, by the presence of the Prime Minister. In an inspiring address, Mr. Attlee declared that the prime duty of all teachers is to train their pupils to become good citizens of a democratic society.

ISI Bulletin

A NEW quarterly journal, *ISI Bulletin*, has been issued by the Indian Standards Institution, *P* Block, Raisina Road, New Delhi. The price is 2*s*., and the first number contains thirty-six pages. The Indian Standards Institution was founded in 1947, primarily as an industrial organisation, but with Government support. The president is Dr. S. P. Mookerjee, Minister for Industry and Supply, and its director, Dr. Lal C. Verman. It has set up four executive committees for agricultural products, documentation, quality control and industrial statistics, and weights and measures, together with engineering, textile and chemical division councils, sponsoring a total of 118 committees and sub-committees. Draft standards on textile shrinkage tests and fireclay refractories have already been published. Apart from much detailed information the *Bulletin* contains the president's address to the general council and three very interesting general articles. The first of these, on the "Standard Atmosphere for Testing", compares average atmospheric conditions in India with those in other parts of the world and makes recommendations, which the Indian delegation was successful in getting accepted by the International Standards Organisation, for alternative 'standard atmospheres' to be adopted for use in industrial testing laboratories in tropical and temperate climates respectively. The second paper, on "Quality Control", is mainly a record of various conferences and papers relating to this subject, largely directed to its applications to the textile industry. The last paper deals with "Weights and Measures". It includes a brief summary of the past and present position in India, and puts forward a proposal for the adoption of the metric system with Indian names for the units, and a series of Indian prefixes and affixes to denote the successive powers (multiples and sub-multiples respectively) of 10. The *Bulletin* gives an impression of vitality which augurs well for the future success of the new organisation.

Scientific Information in India

COMMENTING on the Royal Society's Conference on Scientific Information Services in London last year (see *Nature*, August 21, 1948, p. 279), the *Journal of Scientific and Industrial Research* (*India*) (Nos. 9 and 10, pp. 387, 435 ; 1948) emphasizes the importance of such aids to research and the urgency of evolving a satisfactory system in India. It accepts the view that the primary requirement is a central organisation, maintaining liaison with similar organisations in other countries and directed by a man of science with width rather than depth of interests, who is able to perceive and satisfy the bibliographical needs of a large clientele. The needs of a really adequate information centre, for assembling scientific and technical information from India and elsewhere and for distributing such information, require consideration both from the point of view of organisation and material. The research aspect of information and intelligence work does not appear to have been recognized sufficiently in India; and the editor calls for a lead from the Indian Department of Scientific and Industrial Research towards the organisation of an efficient service on lines emphasized at the Royal Society Conference and already adopted not only by the Department of Scientific and Industrial Research in London but also in Australia, New Zealand and Canada, and by the National Research Council of the United States.

German Wool Industry

THE Wool Industries Research Association has recently prepared "B.I.O.S. Overall Report No. 9: The German Wool Industry during the period 1939–1945" (pp. 56. London: H.M. Stationery Office, 1948. 1*s*. net). The report suggests that in respect of blending, carding, spinning, weaving, dyeing, finishing, shoddy and mungo manufacture, machinery design, operation and production there is little that the British industry can learn from its German counterpart. Much of the latter's woollen yarn industry was judged to be obsolete by American standards with, on the whole, low productivity, and, though allowance must be made for the quality of the raw material in use, the quality of work now being done was said to be poor by most of the investigators. Output was generally higher than with average Yorkshire setts; but the standard of carding was lower. The modified Duhamel scouring process is economical in both alkali and soap, and merits careful examination. Much attention has been devoted by the Germans to by-product recovery, although there is nothing new in principle in the processes used. The exact efficiency of the German worsted industry is difficult to assess; but it would appear that while, compared with Britain, the German industry has the advantage of better buildings, facilities and general amenities, German technicians have made no great mechanical or processing advances. Little advance in research was recorded in the war years, although some work on improving the sensitivity of wool to alkali, increasing the fastness of dyes, on moth-proofing, on low-temperature dyeing and the dyeing behaviour of the Palatine Fast dyes is noted. A bibliography of the reports and documents on which the report is based is appended.

Management Training at Staff College

IN the paper "The Staff College in Training for Management", Mr. N. F. Hall, principal of the Administrative Staff College, reviews his experimental work during the last two years in bringing the College into operation, and this paper has now been issued by the British Institute of Management, together with the introductory remarks of Sir Charles Renold and a report of the discussion, as the first report in the *Winter Proceedings* series of the Institute. Mr. Hall stresses that the task is to make a co-ordinated group out of individual specialists and to increase the capacity of those trained in administration and in different fields of technology to work together. The bulk of the work of each course is carried out by the discussion method, and this ensures that the basic principles of administration and their practical application will be examined. The study of biography has been introduced to provide opportunities for discussing the importance of personality and character in administration and to liberalize a concentrated practical course. While emphasizing the value of a well-balanced admixture of practical experience among the members of each session, Mr. Hall recognizes that the size of any mixed staff college must be small, both because of the importance of all members getting to know each other and because of the limits dictated by the group-discussion method used. Accordingly, great care should be exercised to avoid building up a privileged caste of those who have passed through the Staff College, from which there cannot at present be an annual output of more than about two hundred. As to the length of the course, Mr. Hall thinks it should remain at about three months or else be increased to a year; and for the present he thinks that three months represents a reasonable working compromise.

Fouad I University, Cairo: Faculty of Science

THE annual report, 1946–47, of the faculty of science, Fouad I University of Cairo, gives a brief description of the research activities, including particulars of papers published and some notes on researches in progress. In the Department of Pure Mathematics work is continuing on the distribution of cranial curves and on mortality tables, while in that of Applied Mathematics work is in progress on the unified field theory, the velocity potential of the fluid motion induced by the motion of a cylinder in an infinite mass of compressible fluid, and the effect of polarization on secondary scattered light. In the Department of Physics the subjects under investigation include electron polarization, viscosity of gases, electron diffraction by liquid films, the measurement of atmospheric turbulence, supersonic diffraction through slits and the viscosity of plastics. In the Department of Zoology the study of some biological and morphological aspects of lamellibranchs, the fauna of Egypt, the excretion of reptiles, and the embryology of scorpions is continuing, and a study has commenced of the anatomy, histology and physiology of the digestive system of some Egyptian Lacertilia. In the Department of Entomology work continued on some of the Bombyliidæ of Egypt, and on the biology and ecology of various dung insects.

The Country Journal

THE second number of the recently launched *The Country Journal* contains a collection of articles which should satisfy the varied tastes of those who live and work in the countryside and the unfortunate town-dwellers who wish to do so. There are articles for the farmer, the gardener, the botanist, the ornithologist, the bee-keeper and the member of the women's institute; while in an admirable survey many of the recent books on natural history and rural subjects are classified for the convenience of several types of readers. In the present number of the journal two articles of absorbing interest are those by Frank Illingworth on the countryman's games and Trevor Holloway on curious country place-names. Particulars of the new journal may be obtained from the Worcester Press, Worcester.

Virus Diseases of Lettuce

DANDELION yellow mosaic virus was first reported by B. Kassanis in 1944. He then showed that the disease could also affect lettuce. More recently (*Ann. App. Biol.*, 34, No. 3, 412–421; Sept. 1947) the same author has described the symptoms and transmission of dandelion yellow mosaic and of lettuce mosaic. He also reports the isolation of cucumber mosaic from naturally infected lettuce. Lettuce is more susceptible to dandelion yellow mosaic than is its name host. The aphid *Myzus persicæ* transmits lettuce mosaic, but not dandelion yellow mosaic, which is, however, spread by *Myzus ornatus*, *M. ascalonicus* and *Aulacorthum solani*. The common lettuce aphid, *Nasonovia ribicola*, rather perversely transmitted neither virus. Lettuce mosaic is found in most samples of commercial seed; but dandelion yellow mosaic is not seed-borne.

Frank B. Jewett Fellowships: New Awards

THE American Telephone and Telegraph Co. has awarded the Frank B. Jewett Fellowships for 1949–50 to the following: Dr. Harish-Chandra, a graduate in mathematics and theoretical physics of the University of Allahabad, the Indian Institute of Science in Bangalore and the University of Cambridge, who has done considerable research on the theory of elementary particles and is at present working on the theory of Lie algebras at the Institute for Advanced Study, Princeton; Dr. James A. Jenkins, a graduate in mathematics and physics of the University of Toronto and Harvard University, who is engaged in research relating to topological mapping problems at Harvard University; Dr. Robert Karplus, a graduate in chemical physics of Harvard University, who is engaged in nuclear research at the Institute for Advanced Study, Princeton; Dr. Joaquin Mazdak Luttinger, a graduate in physics of Brown University and the Massachusetts Institute of Technology, who has been studying at the Physikalisches Institut, Zurich, and will continue his research there on the theory of the superconductive state; Dr. David Emerson Mann, a graduate in physics and chemistry of the City College of New York and of the University of Chicago, who is engaged in research in quantum mechanics at the University of Minnesota; Dr. Harvey Winston, a graduate in chemistry of Columbia College, who will undertake research in crystallography. These fellowships are designed to stimulate and assist post-doctorate research in the fundamental physical sciences and are awarded on the recommendation of a committee of seven from the Bell Telephone Laboratories. The awards carry a grant of 3,000 dollars to the recipient and 1,500 dollars to the institution at which the research is done.

Textile Institute: Awards

DR. D. A. CLIBBENS, of the British Cotton Industry Research Association, has been made an honorary fellow of the Textile Institute, in recognition of his work on the chemistry of cellulose and the development of analytical and testing methods for the control of bleaching, mercerizing and dyeing. This distinction has only been conferred on eight previous occasions. Dr. S. A. Shorter, formerly of the British Cotton Industry Research Association, has been awarded the Warner Memorial Medal, in recognition of original investigation, the results of which have been published in the *Journal* of the Institute. The Institute Medal, for distinguished services to the textile industry in general and to the Institute in particular, has been awarded to Messrs. A. W. Bayes and Harold Ashton, and the Service Medal, for valuable services rendered to the Institute, to Messrs. H. C. Barnes and S. Kershaw.

Symposium on Engineering Structures at Bristol

THE Colston Research Society has arranged with the University of Bristol a series of symposia, to be held annually, on selected research topics of current importance. The first of these, on cosmic rays, took place last September, and the second, on engineering structures, will be held during September 19–23. At this symposium the papers read will deal mainly with non-linear aspects of the behaviour of engineering structures; but some more general papers reviewing research work on various kinds of engineering structures will be included. A number of men of science, well known in this field, have been invited, and the symposium will be open to all research workers and students connected with this subject. However, the numbers will be limited to eighty, and requests for admission should be sent, before July 1, to Prof. A. G. Pugsley, Merchant Venturers' Technical College, Bristol 1.

The Night Sky in May

FULL moon occurs on May 12d. 12h. 51m., U.T., and new moon on May 27d. 22h. 24m. The following conjunctions with the moon take place: May 6d. 20h., Saturn 3° S.; May 17d. 14h., Jupiter 5° N.; May 26d. 16h., Mars 2° S.; May 27d. 12h., Mercury 0·8° S. Mercury is an evening star, setting at 21h. 10m., 21h. 43m. and 20h. 16m., at the beginning, middle and end of the month, respectively; but in the latter case it is too close to the sun to be observed. The planet attains its greatest eastern elongation on May 10. Venus is an evening star and can be seen for a short time in the western sky after the middle of the month, setting 35 min. and nearly an hour after the sun on May 15 and 31, respectively. Mars is a morning star but rises too soon before the sun for favourable observation. Jupiter rises at 1h. 30m., 0h. 35m. and 23h. 33m., on May 1, 15 and 31, respectively, and is visible for a few hours before sunrise. The planet is stationary on May 20. Saturn is visible until after midnight, setting at 2h. 40m., 1h. 45m. and 0h. 45m., at the beginning, middle and end of the month, respectively, and is stationary on May 1. Only one occultation of stars brighter than magnitude 6 occurs, λ Canc. disappearing at 21h. 30·6m. on May 4.

Announcements

THE L. T. Hobhouse Memorial Trust Lecture will be delivered at King's College, University of London, on May 12, at 5.30 p.m., by Prof. V. Gordon Childe, professor of prehistoric European archæology in the University of London, who will speak on "Social Worlds of Knowledge". Admission will be free, without ticket.

A RESEARCH scholarship of the value of £400 per annum and tenable for two years has been offered by the Aluminium Development Association to encourage and facilitate research in the application of light alloys to ship construction. Full particulars of entry, which closes on July 31, can be obtained from the Secretary, Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

Action of Nitrogen Trichloride on Proteins: Progress in the Isolation of the Toxic Factor

PREVIOUS work by Mellanby[1] and Moran[2] has shown that treatment of many proteins with 'Agene' (nitrogen trichloride) produces material which when fed to dogs causes hysteria and epileptiform fits. Radomski, Woodward and Lehman[3] found that rabbits are also sensitive to nitrogen trichloride-treated proteins, and we have found it convenient to employ these animals in preference to dogs since they obviously have considerable advantages in the routine semi-quantitative toxicity assays involved in the course of purification experiments.

We have employed as starting material finely powdered zein treated with nitrogen trichloride at the level of 5·5 mgm./gm. by absorption from a mixture of nitrogen trichloride vapour and chlorine diluted with moist air. 5 gm. of this treated zein is sufficient to produce running fits and convulsions in a 1-kilo rabbit within forty-eight hours. The corresponding amount for a dog is about 25 gm.

The first important point in the purification process is that toxic material can be recovered from treated zein after hydrolysis for three hours in boiling hydrochloric acid (initially 8 *N*). However, it is more convenient, in order to reduce the quantities of material to be processed, first to concentrate the toxic factor by digestion of treated zein with pancreatin. Dialysis through 'Cellophane' separates the toxic factor in the dialysate, which is then extracted successively with water-saturated *n*-butanol at 80° and then with phenol in the cold. The toxic factor remains in the aqueous phase after butanol extraction and is afterwards recovered from the phenol-rich phase. We have made numerous attempts to purify further the phenol-soluble fraction by means of partition chromatography. This fraction is thought to be largely a complex mixture of amino-acids and peptides, and using *n*-butanol as developing solvent on columns of silica gel or starch, the toxic factor is concentrated in a stationary or very slowly moving band, while fast-moving bands can be eluted. Using phenol on columns of silica gel, the toxic factor moves in the fastest-running band. However, considerable losses of toxicity have invariably been encountered on columns of this type, and accordingly it was decided to hydrolyse with acid before attempting any further purification.

Phenol-soluble material is hydrolysed by boiling under reflux for three hours with hydrochloric acid (initially 8 *N*) (the bulk of excess hydrochloric acid removed by repeated evaporation *in vacuo* and the residue redissolved in water), again repeatedly extracted with hot butanol and decolorized with charcoal activated with acetic acid according to the method of Tiselius[4].

The behaviour of this material has been examined in columns of silica gel using phenol as solvent, on anionic resin exchange columns, when subjected to electrodialysis and on fractional precipitation with acetone. These methods have been used individually and in combination; at all stages, fractions have been examined by means of paper chromatography.

A sequence which has been found consistently reproducible is as follows. The decolorized acid solution is brought to 95 per cent acetone concentration, when the toxic factor is distributed between the gummy precipitate and the soluble fraction. The precipitate, redissolved in water, is electrodialysed in a three-compartment cell of the type used by Albanese[5], and the material from the middle compartment is then applied to a resin exchange column ('Zeo-Karb' 215). On elution with ammonia (0·15 *N*) the amino-acids appear in the effluent in the same order as that described by Partridge[6], the toxic factor being eluted in a broad band following proline and extending to the point of the ammonia 'break through'.

When examined on paper chromatograms, the material of the toxic band is found to contain several ninhydrin-reacting substances; namely, proline, a substance *A* (probably methionine) with an R_F value of 0·75, and unidentified substances giving a group of purple spots of R_F values in the range 0·1–0·3 (Whatman No. 4 paper run with phenol). By precipitation with acetone it is possible to remove this last material and still retain toxicity, thus showing that these substances of low R_F value are impurities and cannot be identified with the toxic factor; separate feeding tests confirm that they are non-toxic. Again, when the toxic band is treated by partition chromatography on columns of silica gel, using phenol as solvent, toxic material is obtained both from the fraction first eluted (containing proline and *A*) and also from the slower-moving fraction containing the substances of lower R_F. The inference, therefore, is that the toxic factor cannot be related to any known ninhydrin spot on paper chromatograms. Evidence in support of this, but admittedly not conclusive, is found in the fact that untreated zein degraded and fractionated by exactly the same procedure as above is entirely non-toxic when fed to rabbits, and yet gives a pattern of ninhydrin spots identical with that given by toxic material. Another interesting fact is that when our most concentrated toxic material is hydrolysed by acid under conditions which are normally considered to give complete hydrolysis of protein and peptides, no new ninhydrin-reacting substances are revealed. This would suggest that the toxic factor is not a peptide, unless it is present in amount below the sensitivity of the ninhydrin test.

A rough measure of the progress of purification by the various steps is shown in the accompanying table. The toxic dose refers to the dry weight of the material which will produce convulsive fits in a rabbit of weight approximately one kilo within forty-eight hours.

Step	Fraction	Toxic dose
	Treated zein	5 gm.
Pancreatin digestion	dialysate	1·5 ,,
Butanol extraction	aqueous phase	1·0 ,,
Phenol extraction	phenol phase	0·6 ,,
Acid hydrolysis and butanol extraction	aqueous phase	0·3 ,,
Charcoal and acetone precipitation	precipitate	0·15 ,,
Electrodialysis	middle compartment	30 mgm.
Ion-exchange displacement	end fraction	4 ,,
Acetone precipitation and silica gel	—	2 ,,

The toxicity of our most concentrated material represents, therefore, a 2,500-fold increase on that of the original treated zein.

It should be mentioned that both stages of the last step, precipitation with acetone and recovery from a silica gel column, are not entirely satisfactory as a method of purification, since they are erratic and occasionally involve loss of toxic material. The silica gel column is, however, consistent and reproducible with respect to the known ninhydrin reactants.

Complete isolation and characterization of the toxic factor require operations on a scale larger than has been possible for us hitherto, but these are now in hand.

A Morphological Distinction between Neurones of the Male and Female, and the Behaviour of the Nucleolar Satellite during Accelerated Nucleoprotein Synthesis

GENETICISTS have long emphasized that 'maleness' and 'femaleness', so far as chromosome content is concerned, are projected from the fertilized ovum into the morphologically and functionally specialized somatic cells. It appears not to be generally known, however, that the sex of a somatic cell as highly differentiated as a neurone may be detected with no more elaborate equipment than a compound microscope following staining of the tissue by the routine Nissl method.

The observations to be recorded here apply to the cat primarily, since the cat is used routinely in this laboratory for investigations in experimental neurocytology. The nuclei of nerve cells contain a prominent nucleolus which stains readily with such basic dyes as cresyl violet and thionin. The difference in nuclear structure between neurones of adult male and female cats rests on the degree of development of a second body, which is much smaller than the nucleolus. The latter body is more or less intimately associated with the nucleolus and, like the latter, stains well with basic dyes. It has been described by many authors under various names. The term 'nucleolar satellite' will be used in this report, in the hope that students of chromosome morphology will not object too strenuously to the use of the word 'satellite' in this connexion.

Typically, nerve cells of mature *female* cats contain a well-developed nucleolar satellite which is located, as a rule, immediately adjacent to the nucleolus (Fig. 1). A single satellite is usually present; but two may be encountered. The satellite, if more deeply stained than the nucleolus, may be seen in all nerve cells which are sufficiently large to have a prominent nucleolus. More often, the intensity of staining of the nucleolus and its satellite is similar. Under these conditions, the satellite is seen in approximately 30–40 per cent of cells, being invisible when eclipsed by the nucleolus.

As a rule, nerve cells of mature *male* cats (Fig. 2) contain a poorly developed nucleolar satellite, seen only infrequently. When visible, it is situated adjacent to the nucleolus and is near the limit of resolution with an oil-immersion objective.

In a small proportion of animals of both sexes, nucleolar satellites of intermediate size are present. These exceptional cases raise several interesting questions which are now under investigation.

The morphological distinction, therefore, between neurones of the mature male and female cat is so

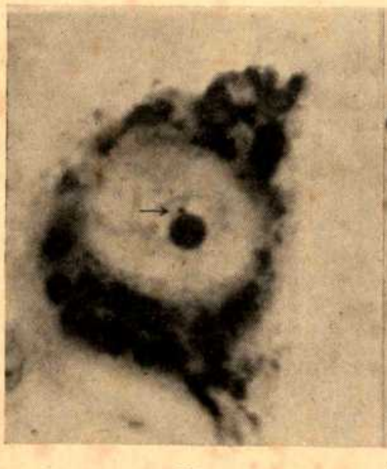

Fig. 1

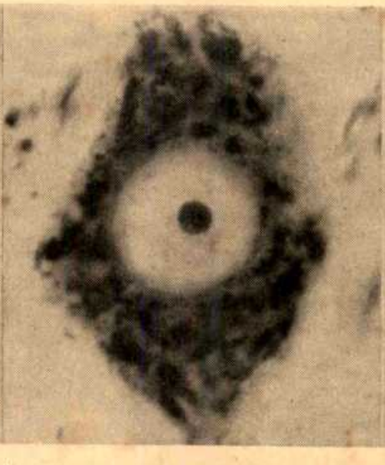

Fig. 2

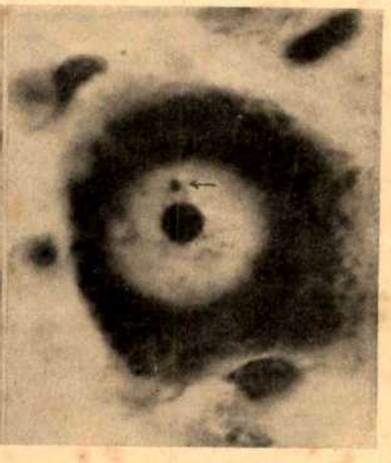

Fig. 3

Fig. 1. Normal motor neurone from the hypoglossal nucleus of a mature female cat showing the usual morphology of the nucleolar satellite (indicated by arrow) in the female. Cresyl violet stain, × 1,400

Fig. 2. Motor neurone from the hypoglossal nucleus of a mature male cat. The nucleolar satellite is absent, the typical condition in the mature male. Cresyl violet stain, × 1,400

Fig. 3. Motor neurone from the hypoglossal nucleus of a mature female cat 108 hours following electrical stimulation of the corresponding hypoglossal nerve for a period of 8 hours. Associated with intense synthesis of cytoplasmic ribose nucleoproteins, the nucleolar satellite (indicated by arrow) tends to move away from the nucleolus. Cresyl violet stain, × 1,400

clear that sections from the brain, spinal cord or sympathetic ganglia of animals of both sexes may be readily sorted into two groups without prior knowledge of the sex, with only an occasional section remaining in which the distinctive morphological feature is of an intermediate character.

That there should be a morphological difference in the inter-mitotic nucleus of mature, differentiated cells, according to their sex, is not surprising in view of what is known concerning the relation of the nucleolus to the chromosomes. The nucleolar chromosomes are frequently the sex chromosomes[1]. One may postulate that such is the case in the cat. The nucleolar satellite may be derived from the heterochromatin of the sex chromosomes. Further, the cells of the female cat, because of the duplicated X-chromosomes, may be endowed with a greater quantity of nucleolar associated heterochromatin than are the cells of the male cat. Caspersson and Schultz[2] noted a difference in the absorption curves obtained with ultra-violet light, indicating a difference in nucleoprotein content, in cells of male and female *Drosophila*. These comments suggest the importance of taking the sex into consideration in cytochemical studies of nucleoprotein metabolism.

A preliminary examination of sympathetic ganglia of human males and females indicates that a similar sex difference in nuclear morphology exists in the human. Whether or not such sex differences in nuclear structure will be found in a given species would probably be determined, in part, by the relationship of the nucleolus to the sex chromosomes and by the disparity in size and composition between the X- and Y-chromosomes. It is probable that somatic cells of various tissue, characterized by large nucleoli, will display similar distinctive nuclear differences according to the sex.

We wish to emphasize that these observations apply to mature animals. The influence of the age factor and other aspects of the nucleolar satellite under normal and experimental conditions will be published in later reports.

It is of interest to experimental neurocytologists that the position of the satellite relative to the nucleolus is a useful aid in assessing the physiological state of the cell. In a series of experiments, to be reported in detail elsewhere, depletion of the Nissl material of motor neurones was produced by prolonged electrical stimulation of the hypoglossal nerve. The nucleolus enlarges during the recovery phase, coincident with the re-appearance of abundant Nissl material in the cytoplasm. This observation is in agreement with the views of Caspersson and his co-workers, who regard the nucleolus and the nucleolar associated chromatin as instrumental in the synthesis of ribose nucleoprotein, an important component of the Nissl substance (see Hydén[3] for references). It is of particular interest in the present connexion that the satellite moves away from the nucleolus during the period of intense ribose nucleoprotein synthesis (Fig. 3). The satellite may, in these circumstances, lie in contact with the nuclear membrane. The movement of the nucleolar satellite may be passive, resulting from the outpouring of materials (nucleotides or nucleic acids ?) from the region of the nucleolus. On the other hand, complex factors, such as forces of an electrical nature, may be at work. In any case, the position of the satellite is another item for observation, in addition to the appearance of the Nissl substance, in attempting to assess the physiological state of the neurone under experimental conditions. This criterion may be applied to best advantage, of course, only to the cells of female cats. The nucleolar satellite is occasionally found free in the nucleoplasm in control cells. This is regarded as a further indication of the variation in the physiological state of members of a nerve-cell population under normal conditions.

It is hoped that this brief preliminary report may encourage closer attention to the nucleolar satellite in the abundant material available to laboratories of neuropathology in which the Nissl method is constantly in use as a routine staining technique. The possibility that fundamental alterations in the nucleolar associated chromatin may have an important bearing on malignancy gives added interest to these observations.

These observations were made in the course of experiments on the effect of activity on the neurone being done in this laboratory for the Institute of Aviation Medicine, Royal Canadian Air Force. The senior author wishes to thank various members of the staffs of the Department of Neuropathology, University of Toronto, and of the Montreal Neurological Institute, for very helpful discussions.

Effect of a South African Native Diet upon Rats

YOUNG rats of the Wistar Institute strain aged five to six weeks and weighing 70–100 gm. were fed on the Gillman diet[1]. This consisted of liberal quantities of a thick mealie-meal porridge and fermented cow's milk. Animals were killed after they had been on this diet for four and a half and six months. All, except two in the latter group, showed an abnormal bromsulphalein retention in the serum; but the serum proteins, thymol turbidity, thymol flocculation and colloidal gold tests were within normal limits.

The following organs were examined histologically: liver, kidney, spleen, upper incisor teeth and periodontal tissues. The lower ends of the radii and ulnæ and the upper ends of the tibiæ were examined by the line test[2]. Microscopy of the livers revealed relatively little fatty change, but practically complete absence of glycogen in all except the two rats, which showed a normal bromsulphalein excretion. In these two rats the amount of glycogen present in the liver was normal. The kidneys and spleens of all animals showed no abnormal histological changes. Interesting pathological changes were, however, found in the incisor teeth and periodontal tissues, which are best described under three heads.

(1) The animals were suffering from a sub-acute vitamin A deficiency, which was not severe after four and a half months, but was much more marked after six months. This was seen in the teeth of the younger rats as a lack of regression of the odontoblasts, which

became included in the dentin, especially on the lingual side, the predentin eventually disappearing. This phenomenon was seen on both sides of the teeth in the older rats; in addition, these teeth showed an atrophy of the odontoblasts on the lingual side at the formative end and a subnormal production of dentin, together with over-production of dentin on the labial side; apposition instead of resorption was found on the periodontal side of the premaxillary labial alveolar bone, which is also typical of vitamin A deficiency[3]. The only microscopic change characteristic of vitamin A deficiency which was not present was keratinization of the naso-lacrimal duct epithelium; but in long-standing sub-acute vitamin A deficiency this sometimes does not occur. In some of the older rats a chronic infection was present, as shown by an invasion of small round cells, plasma cells, eosinophils, macrophages, etc., in the mucous glands at the formative end of the tooth and elsewhere. The lingual dentin at the incisal end of the tooth of one of the older rats contained Gram-positive and -negative cocci, and the underlying pulp had an inflammatory reaction. The organisms were found in the dentin tubules and in the cavities containing the vascular and cellular inclusions. Externally, the animals showed no signs of vitamin A deficiency, and the teeth had kept their orange pigment.

(2) A rachitic condition was present, seen as an extreme widening of the predentin on both sides of the tooth. In the older animals some healing had occurred. The epiphyseal cartilages of the long bones were not wider than usual, and the fundic bone of the alveolus was also normal, so that it would appear that this rickets was of the low-calcium type. This surmise is supported by the fact that the calculated calcium and phosphorus contents of the diet were 0·057 and 0·16 per cent respectively, with a Ca : P ratio of 0·36.

(3) In all rats, but especially in the older ones, the enamel organ and particularly the ameloblasts showed early and abnormal atrophy. This was accompanied by the presence of many macrophages in the labial alveolar periosteum, especially towards the incisal end of the tooth. In the younger rats, these cells contained a few granules; but in the older animals they were laden with many conspicuous granules. In the older rats, the pigment layer of the enamel persisted, after removal of the rest of the enamel during the histological decalcification process. It was attached to the enamel organ, from the level of the granule-containing ameloblasts up to the alveolar crest, and the granule-containing ameloblasts were usually conspicuous. Tests for iron were positive for this pigmented layer, for the granules in the macrophages and for those in the ameloblasts. It seems almost certain that the granules in the macrophages were the same in composition as the pigmented enamel. Chase[4] has described an invasion of macrophages in conditions where the enamel organ was degenerative, and we have also seen this in other specimens where the enamel organ was atrophying from a variety of causes, but never so markedly as here.

From the evidence of the teeth it seems that a multiple deficiency was present. It is possible that the vitamin A or vitamin A precursors present in the two constituents of the diet were partially destroyed by oxidative processes when the ingredients were mixed together, especially when fermented milk was used. Györgyi[5] has reported that vitamin E prevents the hepatic injury caused by certain deficient diets, and vitamin E is known to afford protection to carotene[6]. However, no correlation at all was found between the tooth changes and the alterations in the bromsulphalein serum retentions in the present experiments; this does not support the proposition that both are caused by the same deficiency. The rachitic condition is explained by the very low calcium and phosphate contents of the diet and by the abnormally low Ca : P ratio. The changes in the pigment layer of the enamel have not been described before, and are being further investigated.

A New Mutant in the Progeny of Mice Treated with Nitrogen Mustard

The ability of the mustard compounds to induce gene mutations and chromosome re-arrangements was first detected in experiments with *Drosophila melanogaster*[1-3]. Subsequent investigators showed that this ability extends to all organisms which so far have been tested: *Neurospora*[4], *Tradescantia*[5], *Penicillium*[6], barley[7], bacteria[8] and *Vicia*[9]. There can be little doubt that the mutagenic ability of the mustards is as general as that of X-rays. On the other hand, there is no *a priori* reason for assuming that mustards applied to other organisms will exhibit the same peculiarities of genetical effect which have been found in the work with *Drosophila*, namely, a relative shortage of large re-arrangements[2], deferred action[10,11], and preferential action on immature sperm[12].

It seems worth while to study mustard effects in different species from this point of view. For obvious reasons warm-blooded animals, in particular mammals, are of special interest. It is known that in mammals also mustard gas acts as mitotic poison[13]. This selective action on dividing cells is made use of in the therapeutic treatment of leukæmia and Hodgkin's disease[14]. Proper tests for the production of mutations and chromosome re-arrangements in mammals have, however, not yet been attempted. Apart from their theoretical interest, such tests might acquire practical significance, if in future it should become possible to use nitrogen mustards not only as a palliative in malignant disease, but also to effect more or less permanent cures; for in such cases it would be important to assess the effect of the treatment on the gonads of a patient who afterwards may be able to reproduce.

We have recently started experiments in which male mice of an inbred wild-type strain are treated with a nitrogen mustard (N-methyl di-(2-chloroethyl)-amine), and the progeny are tested for translocations (heritable semi-sterility) and visible mutations. In the first three experiments, twelve mice were each given 0·08 mgm. by intraperitoneal injection. All but one died within a few days. Some of the mice of the third experiment mated before death and produced litters of normal size. Nine of their sons were tested for semi-sterility with negative results. In the second experiment, two out of three treated mice died without progeny. The third survived and mated at least once in the week following treatment. No offspring, however, were produced until about two months later, when full fertility was restored. Of the twenty-four offspring born, sixteen were tested for the presence of recessive gene-mutations by outcrossing each and then backcrossing the offspring to them or mating the offspring *inter se*. In one of these matings a hitherto unknown mutant in its first litter was segregated.

Only a very brief description of the new mutant can be given here. It appears to be due to a single recessive gene, giving normal ratios and having full penetrance. Its visible effects on the mouse are many: the most striking are a peculiar folding of the ears from about one to three weeks of age, absence of hairs on the tail and behind the ears, small kinks at the extreme tip of the tail, and a short and rather thin coat with the hairs tending to point toward the midline of the back. These effects are all very regular in their appearance, except the thinness of the coat, which varies somewhat. Both sexes are fertile, and the females are able to rear their young.

The occurrence of one mutant cannot, of course, be certainly ascribed to the mutagenic action of the treatment, even considering the small number of gametes tested. The discovery of spontaneous visible mutations in mice is, however, a very rare event, even in inbred lines, and the discovery of one among sixteen gametes seems to be extremely improbable. In fact, not all the sixteen gametes were adequately tested. It was calculated, by a method described elsewhere[15], that the equivalent number of fully tested gametes was only 11·3. It seems, therefore, more likely that the mutation was induced than spontaneous, and the experiments are being continued.

Tissue Distribution of a Radioactive Spinal Anæsthetic

When a spinal anæsthetic leaves the subarachnoid space and the neural elements contained therein, it enters the general circulation, by which agency it is distributed among the various tissues of the body. Hitherto, on account of the technical difficulties attendant upon the estimation of an anæsthetic substance at low concentration in the presence of gross tissue excess, precise studies of tissue distribution have not been made.

To investigate various problems associated with local and spinal anæsthesia, I prepared a radioactive anæsthetic, dibromoprocaine hydrobromide[1]. For the purpose in hand, a reasonably active preparation was requisite, and this was obtained by irradiation in the chain-reacting pile of 30 c.c. of ethylene dibromide containing 5 per cent of aniline[2], followed by a modified Szilard–Chalmers's extraction. The radioactive bromine finally obtained as silver bromide was treated in the manner previously described[1] and the product dibromoprocaine hydrobromide converted into dibromoprocaine hydrochloride, so as to eliminate the ionizable bromine.

The established pharmacology of the nuclear halogens indicates that the bromine atoms are not likely to be split from the benzene nucleus in the course of its metabolism, and I have confirmed this. Consequently the estimation of the radioactivity of specimens derived from the various tissues should provide an index of the concentrations of the original drug in terms of its benzene nuclei, notwithstanding any further additions which may be made to it during its sojourn in the body, and the fate of the side chain.

Cats were employed in the first series of experiments, and these received, by lumbar puncture, doses of dibromoprocaine hydrochloride varying between 0·007 and 0·03 gm. Urine was obtained by catheterization, cerebrospinal fluid by lumbar puncture, bile by aspiration of the gall bladder and blood by cannulation of the carotid artery or ventricular puncture. Autopsies were performed at periods of 1–39 hr. after the administration of the anæsthetic, and specimens taken from the organs to be examined. The tissue samples so obtained were broken down in lithium hydroxide solution under reflux, and the resulting fine suspensions estimated by means of a scaling unit and 'liquid' counter.

In the second series, the anæsthetic was administered intravenously, so as to study the effects on tissue concentration of higher blood levels.

In the intrathecal series, the blood levels fell between 5·4 and 1·3 µgm. per c.c., while, in the case of the intravenous series, maximum blood levels of 44 µgm. per c.c. were investigated.

The tissues examined were skin, kidney, liver, duodenum, spleen, muscle, lung, testis, thyroid, spinal cord, spinal roots, medulla oblongata and sciatic nerve. Estimations of urine, bile and duodenal contents, cerebrospinal fluid and fæces were also made.

Apart from spinal cord and spinal roots, only kidney and liver showed a concentration of the drug above that obtaining in the blood, the former reaching a maximum of 9 times and the latter 3 times the blood concentration; while their secretions, urine and bile, showed maximal concentrations of 133 times and 27 times that of the blood respectively; the concentration of the drug in the duodenal contents followed that of the bile. Investigation of the fæces showed that part at least of the dibromoprocaine molecule was excreted *via* the gut.

The concentrations of anæsthetic in spinal cord, roots and cerebrospinal fluid were not directly dependent on blood concentration, since the drug was administered by lumbar puncture. It is of interest, however, that the spinal roots showed a higher concentration of anæsthetic per unit mass than did the cerebrospinal fluid in which they were bathed.

As regards the drug content of the remaining tissues, the lung showed the highest and muscle tissue (gastrocnemius) the lowest, attaining 0·8 and 0·1 times blood concentration respectively: the other tissues fell between these two limits.

With increased time between administration and autopsy, a slight increase in the blood-tissue ratios was observed, due, probably, to leakage from the vascular bed of the organs to the tissues themselves; this effect was maximal about twenty hours after administration of the spinal anæsthetic, with subsequent steady decline. In the case of the liver and kidney, tissue concentration was greatest about 1½ hr. after injecting the drug, at which time blood and bile concentrations were also maximal.

When the drug was given intravenously, the cerebrospinal fluid in the lumbar theca showed a barely estimable amount of tracer, while the cord showed 0·05–0·1 times and the roots 0·3–0·4 times blood concentration.

At high blood levels, the concentrating activity of liver and kidney appeared to decrease, due presumably to a 'swamping' of these organs; but variations in blood levels had little effect on the blood-tissue ratios elsewhere. Tracer could be detected in the circulation at considerable intervals (70 hr.) after its administration, and, at this period, both liver and kidney concentrations were also observed to drop, in spite of a persistent blood level at which active concentration had previously occurred.

Epidermal Mitosis in Relation to Sugar and Phosphate

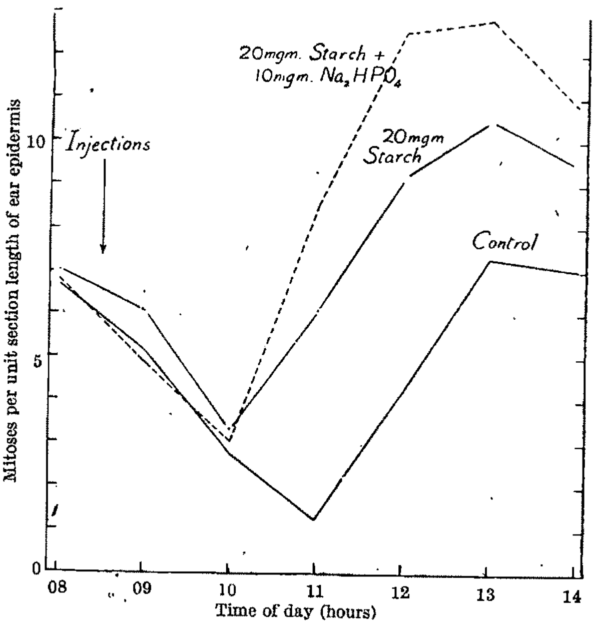
DESCRIPTIONS have been given of the diurnal mitosis cycles in the ear epidermis of the adult male mouse, and the conclusion has been reached that the form of these cycles is determined by the daily routine of activity and of rest[1]. During bodily activity, the mitosis-rate is low, and during sleep and rest it is high. In extending these observations, two further important facts were noticed, namely, that excessive muscular exercise is followed by an abnormal depression of the mitosis-rate[2], and more recently, that the same effect can be induced by extreme cold. Since in both these situations there is a drain on the sugar reserves of the body, in the one case for muscle contraction and in the other for heat production, it was suspected that an abundance of sugar may be a critical factor in the development of a high mitosis-rate.

Variations in the mitotic activity of the ear epidermis following injections of starch alone and of injections of starch together with disodium hydrogen phosphate at 08·30 hr.

Time of day	No. of observations per group	Av. numbers of mitoses per cm. length of sections cut 7 μ thick		
		of 10 control mice injected with saline alone	of 10 mice injected with 20 mgm. of starch in saline	of 10 mice injected with 20 mgm. of starch and 10 mgm. of $Na_2HPO_4.2H_2O$ in saline
08·00	100	6·6 ± 0·19	7·0 ± 0·11	6·7 ± 0·12
09·00	100	5·1 ± 0·18	6·1 ± 0·11	4·9 ± 0·10
10·00	100	2·7 ± 0·06	3·3 ± 0·08	3·1 ± 0·09
11·00	100	1·3 ± 0·05	6·1 ± 0·19	8·5 ± 0·14
12·00	100	4·0 ± 0·10	9·4 ± 0·14	12·6 ± 0·21
13·00	100	7·3 ± 0·15	10·5 ± 0·12	12·8 ± 0·25
14·00	100	7·0 ± 0·14	9·5 ± 0·16	10·8 ± 0·18

After preliminary experiments, the following method of administering extra sugar to a mouse was adopted. A subcutaneous injection of a solution of 20 mgm. of starch in normal saline was given to each animal at 08.30 hr. This resulted in a steep rise in the concentration of the blood sugar, which reached a maximum at about 10.00 hr. and returned to normal soon after midday. The accompanying changes in the epidermal mitotic activity were followed by the removal of pieces of ear at hourly intervals from 08.00 to 14.00 hr., and typical results from one of these experiments are shown in the accompanying table. It should be noted that only male mice were used in order to avoid the effects of the œstrous cycle. The results show clearly that a marked stimulation of mitotic activity followed the injection of the starch. There was a time lag of about 1½ hr. before the effect began to develop, but after that the rise in mitotic activity was rapid. The later and smaller rise in the mitotic activity of the control mice was due to the effect of the afternoon sleep period.

The most plausible theory of the function of sugar in stimulating mitotic activity seems to be that it acts as a source of energy. This being so, it might be expected that interference with the process of phosphorylation by means of phloridzin injections would depress mitotic activity, and this has, in fact, been



The variations in the mitotic activity of the ear epidermis of adult male mice following injections of starch and of starch together with disodium hydrogen phosphate confirmed. Conversely, it might also be expected that by injecting phosphate together with starch an even greater mitosis stimulation would be achieved. That this also is the case is shown in the table and in the graph.

This demonstration of the importance of sugar to the process of cell division sheds light on several well-known phenomena, of which the following may be selected for comment. It is common knowledge that the vaginal epithelium becomes charged with glycogen, and produces what appears to be lactic acid, at about the time when it develops high mitotic activity in response to œstrogenic stimulation[3]. Similarly, it has been shown[4] that the administration of œstrogens causes a considerable increase in the blood-sugar level, in apparent preparation for the wave of mitotic activity which follows such treatment. Finally, it is also appropriate to notice here that the induction of a hyperglycæmic condition in canaries favours the rapid multiplication of the malarial parasite *Plasmodium cathemerium*, with a consequent increased death-rate among the hosts[5]. Conversely, in canaries made hypoglycæmic with insulin, fewer parasites develop and larger numbers of the birds survive the infection. During the present work it has also been demonstrated that a reduction in the blood-sugar level following injections of insulin is accompanied by a severe depression of epidermal mitotic activity. All these observations are being published in full elsewhere.

Relation of Molybdenum and Manganese to the Free Amino-Acid Content of the Cauliflower

MOLYBDENUM[1,2] and manganese[3,4] are both believed to be concerned in the chain of reactions beginning with the reduction of nitrates and ending in protein assimilation in higher plants, although they may also have other functions. It has been shown that lack of either element may result in a marked accumulation of nitrates in the leaves of plants. 'Soluble nitrogen' and protein nitrogen fractions also may be less when molybdenum is withheld, but may be nearly normal in the absence of molybdenum when ammonium sulphate is used instead of nitrate as a source of nitrogen[2]. A relationship between manganese and molybdenum has been reported for flax grown in water culture[5,6], where the harmful effects of excess of manganese (and of certain other metals) were reduced by additional amounts of molybdenum.

As there is no evidence that either of these elements can replace the other, it may be assumed that they act independently in the chain of reactions occurring between nitrate reduction and protein formation.

The present note gives preliminary results of experiments designed to study the interrelationships of molybdenum and manganese and to obtain evidence of the reactions catalysed by these elements and their sequence.

Cauliflower plants, variety Majestic, were grown in sand culture using the technique already described[1], with three levels each of molybdenum (nil, 0·015 and 9·5 p.p.m.) and of manganese (0·0055, 0·55 and 55 p.p.m.), ranging for each element from deficiency through normal to toxicity. These plants provided material for the study of nitrate accumulation, as determined on fresh tissue extracts[7], and of the free amino-acid present in the 70 per cent alcoholic extracts of partly expanded leaves. The presence of amino-acids was followed by paper chromatography[8], as recently applied to plant tissues by Dent *et al.*[9] and by Allsopp[10]. Preliminary one-dimensional chromatograms (phenol as solvent) showed variations in amino-acid content quite clearly. Two-dimensional chromatograms (phenol and collidine as successive solvents) permitted identification of several amino-acids[9] by comparison with control runs using known mixtures. The relative concentrations of the amino-acids thus detected were assessed visually in terms of the intensity and area of the colour produced with ninhydrin.

Nitrate accumulated to abnormally high concentrations when either element was deficient, and in this respect the low concentration of manganese appeared to be more conducive to nitrate accumulation than that of molybdenum—an element known to be required in far smaller amounts. Molybdenum deficiency resulted in a marked reduction in the concentrations of most amino-acids, while a few were scarcely affected. The effects of molybdenum and manganese on the free amino-acid content of the leaves were found to be interdependent. Generally a decrease in the molybdenum-level was paralleled by a reduction in the amino-acid concentration, while a similar change of manganese-level acted in the opposite direction, that is, a deficiency of manganese was associated with an increase in amino-acid concentration. The effect of change in molybdenum-level was most marked under conditions of manganese deficiency, while change in manganese-level showed the greatest effect in the presence of a high level of molybdenum.

These changes were particularly great for arginine and were also pronounced with alanine, aspartic and glutamic acids, proline, and an unidentified acid or possibly peptide. The acid amides, asparagine and glutamine, showed similar changes. Another unidentified amino-acid or peptide, however, showed an opposite effect with respect to manganese and appeared more strongly in the presence of an excess of this element. The amounts of some amino-acids were only affected by molybdenum variations from deficiency to normal levels, but for others the effective range lay between the normal and excess levels. Arginine, proline and one of the unidentified substances, however, showed variations over the whole range of molybdenum concentrations. These interdependent effects and the fact that nitrate accumulates in the absence of either molybdenum or manganese may ultimately be explained in terms of the kinetics and mass-action laws of the respective reactions controlled by each element.

The evidence so far available is, however, consistent with the hypothesis that molybdenum and manganese catalyse separate reactions, both of which affect the concentration of amino-acids as intermediate metabolites in nitrogen metabolism. The evidence also suggests that whereas molybdenum controls one or more reactions leading from nitrate to amino-acid production, manganese may function later in the chain when amino-acids already produced are further metabolized.

Tellina magna found in Orkney

DURING Easter 1947, an inspection was made of the seaweed cast up on the west mainland of Orkney. One heavy cast, 3 ft. thick at the water's edge, was found in a sandy bay north of the graveyard north-west of Stromness and opposite the northern extremity of Hoy. The coast is rocky with sandy bays. The rocks are Old Red Sandstone, which erode to form flat slabs sloping towards the sea. About half a mile offshore, a reef of similar rock formation is exposed at low water. There is little chance of anything remaining intact before being cast ashore as the Atlantic waters break on this coast.

The cast weed on this occasion, composed mainly of the fronds of *Laminaria Cloustoni*, had acted as a buffer for several large shells, such as *Pecten*, which were found intact. Normally, such shells become so broken up that they merely add to the shell sand comprising the foreshore in this area.

From among the cast weed a bivalve, 4 in. long, was picked up which when discovered had its two halves hinged; the contents were absent. It has now been identified as *Tellina magna*, a native of the East American coast, North Carolina to West Indies—and is, I am informed, the first recorded instance of a marine invertebrate from the American continent to be found in British waters. Subsequent visits to the same area have produced only limpet shells and one small bivalve. There can be no doubt the cast weed was responsible for bringing the shell ashore intact. How the animal (or its ancestors) crossed the Atlantic can only be speculation. Whether living specimens are to be found off this Orkney coast a dredging expedition must decide.

I wish to acknowledge the interest of the late Mr. R. Elmhirst, of the Marine Biological Station, Millport, Prof. C. M. Yonge, of the University of Glasgow, and Dr. A. C. Stephens, of the Royal Scottish Museum, who were responsible for the identification.

Nuclear Capture of μ-Mesons

IT is well known from delayed-coincidence experiments[1] that negative μ-mesons (mass 215) stopping in light atoms undergo electron decay, whereas those stopping in substances of high atomic number undergo nuclear capture. Both photographic plate[2,3] and cloud-chamber evidence[4,5] shows that very few or none of the μ^--mesons produce nuclear disintegration stars in heavy elements. Counter-work[6] precludes production of photons, though there is evidence for emission of neutrons following meson capture[7,8]. It is of interest to discuss the above evidence in the light of observations on μ-mesons stopping in nuclear emulsions.

The emulsion consists of microcrystals of silver bromide, about $0{\cdot}2\,\mu$ in diameter, suspended in gelatin. Thus, a meson coming to rest in the emulsion will, in general, spend the last fraction of a micron of its range either entirely within heavy atoms, or in light ones. Hence the probability of the meson stopping in heavy or light atoms will be almost independent of the complicated processes of energy-loss below a velocity of about 5×10^8 cm./sec., and can be estimated from experimental data on stopping power. Allowing a positive excess of 15 per cent, we thus calculate that the proportion of mesons which are negative μ-mesons stopping in silver or bromine atoms is 35 per cent. In Kodak electron-sensitive plates exposed to cosmic rays, we in fact observe that 30 ± 6 per cent of the single mesons (the great majority of which are known to be μg particles[3]) fail to give a decay electron on cominto rest. This figure is in good agreement with that obtained by other observers[9].

First of all, it is clear that, quite apart from the fact that it is contrary to the concept of short-range nuclear forces, the rest-energy of the μ-meson cannor be shared directly among several nucleons, othetwise we should inevitably observe fast protons emitted. Let us suppose that the entire rest-energy of the μ-meson is converted into kinetic energy of (*a*) two, and (*b*) one fast neutron. Process (*a*), which is the same as that which probably occurs following negative π-meson capture[2], should result in many cases in the formation of a star, for it is difficuil to see how at least one of the neutrons can avodt producing general nuclear excitation and evaporation. If, as seems extremely unlikely, the latter did not occur, half the resulting palladium or selenium isotopes would be stable, and the remainder would probably be β-active[10]. If these were short-lived isotopes, the proportion of mesons not giving electrons would be greatly reduced. The β-particles would also be immediately distinguishable on account of their small momenta. In actual fact, the momenta of the decay electrons, obtained from Coulomb scattering measurements, appear in all cases to exceed 10 MeV./c. (Where accurate measurements on long tracks are possible, the observed values are much higher than this[9].) Thus any β-decay which might occur would have to be fairly long-lived. In this connexion, it is interesting to note that we have observed no significant difference between the proportion of mesons not giving electrons in plates exposed for six days at Jungfraujoch and developed four days later, and those in plates exposed for three weeks and developed one month later.

In process (*b*) the nucleus (which will be stable to β-decay) must take up the momentum of the neutron, amounting to 450 MeV./c., and will have a range in the emulsion of 1·7 μ [11]. However, from fifteen mesons in Kodak plates not giving decay electrons, we observe only two tracks which could possibly be attributed to recoils. An accurate estimate of the number of such recoils is difficult to obtain because their tracks can easily be confused with Coulomb scattering at the very end of the meson track. We obtain an *upper* limit if we double the number of apparent recoils travelling backwards with respect to the general direction of the meson.

Observations were therefore made on single mesons stopping in fine-grain plates (Ilford *C*2, not capable of recording decay electrons). From 190 meson tracks examined (about sixty of which would be negative μ-mesons stopping in heavy atoms), only eight recoil tracks of ranges of the above order of magnitude were obtained. If all gave recoils, thirty would be backwards and we should expect many more than eight of these to be definitely observable. About one-seventh of the mesons stopping in our plates are π^--mesons producing stars. A further quarter of all the π^--mesons are known to be captured in heavy nuclei and give rise to emission of neutrons only[2] (apart from a recoil); these will be classified as single mesons. They constitute about 5 per cent of all the single mesons and can thus account for at least half the observed recoils; the remainder can be quite reasonably attributed to large-angle Coulomb scattering along the meson tracks. This analysis demonstrates the absence of a homogeneous group of recoil tracks of range $\sim 1{\cdot}7\,\mu$, indicating that the resultant momentum of a nucleus capturing a μ^--meson must be $\leqslant$ 450 MeV./c. The minimum length of recoil observable is estimated at 0·5 μ, corresponding to a recoil momentum of 150 MeV./c.

We must therefore assume that part of the rest energy of the meson is converted into kinetic and rest energy of a light neutral particle. If the remainder appears as kinetic energy of a single neutron, the maximum energy the latter could have, to make the nuclear recoil just unobservable, would be 25 MeV. It is extremely unlikely that a neutron of such low energy would give rise to charged-particle emission in traversing the nucleus, but one or two further neutrons might be evaporated off[12].

Thus, so far as the experimental data permit, we can conclude that the capture of a μ^--meson by a heavy nucleus leads to the process

$$\mu^- + P \rightarrow N + \nu,$$

where ν denotes a light neutral particle (neutrino ?). This is precisely the interaction predicted theoretically[13] as a consequence of the μ-decay of the π-meson, assumed to be of the form $\pi \rightarrow \mu + \nu$.

Electron–Atom Ratios in Alloy Phases as a Monotonic Sequence

1/1, 3/2, 5/3, 7/4, 9/5, 11/6, 13/7 . . . $(2n-1)/n$ . . . 2/1 is a monotonic sequence[1] tending to the limiting value 2/1 when *n* is increased indefinitely. This sequence is a systematic representation of the ratio of the number of free valency electrons to atoms in the well-known Hume-Rothery[2] series of electronic compounds.

For example, in the copper–zinc system, where copper is regarded as monovalent and zinc is divalent, we should have a series of improper fractions, each conforming to the above sequence, and each corresponding to a different phase (see Table 1).

Table 1

Designation	α	β	γ	ε	η
Electron/atom ratio—*Ve*/*A*	1/1	3/2	5/3	7/4	2/1
Empirical formula	Cu	CuZn	$CuZn_2$	$CuZn_3$	Zn
Atomic % Zn	0	50	66·7	75	100
True limits of phase field (400° C.)	0 37	45 49	57 67	77 87	97 100
Crystal structure	f.c.c.	b.c.c.	'γ' type	h.c.p. $c/a = 1{\cdot}55$	h.c.p. $c/a = 1{\cdot}86$
Structural formula	Cu	CuZn	Cu_5Zn_8 Cu_4Zn_9		Zn

In each case the simple formulæ given in the third row fit in well enough with the respective limits of composition, although they are, of course, empirical in origin and are not necessarily related to the crystal structures. The composition limits are decided in other ways, for example, by the free-energy relations between neighbouring phases or by the Brillouin zone theory[3], which does not, however, give rise to any integral values, serving as a rule merely to fix an upper limit to the electronic concentration. For example, the α-phase (face-centred cubic) becomes unstable about the composition limit corresponding to $Ve/A = 1{\cdot}36$ (36 atomic per cent zinc), while the β-phase (body-centred cubic) agrees with $Ve/A = 1{\cdot}48$ (48 atomic per cent zinc).

The range of the ε-phase (hexagonal close-packed) varies greatly from system to system. However, the ratio 7/4 is usually regarded as typical and receives support on theoretical grounds.

An even more striking illustration of a monotonic sequence is afforded by the copper–aluminium system, as can readily be shown. It now appears that in addition to the typical γ-phase (analogous to γ-brass) there are three other closely related phases, two (γ_1 and γ_2) being obtained at room temperature[4], while ε is got by quenching[5]. Further, there is a phase beyond this region (ξ) which has many structural similarities to the γ-phase. Ultimately this complicated region in the equilibrium diagram concludes with the η-phase (CuAl). There are, in all, eight different structures with from one to two free valency electrons per atom. Within each of these phase fields, the ratio of the numbers of free valency electrons to atoms may be represented by the equation $Ve/A = (2n - 1)/n$. Table 2 shows how well the monotonic relationship is observed.

The empirical formulæ $CuZn_2$ and Cu_2Al here allotted to the γ-phase are included well within the respective composition limits of these phases, although they do not correspond with the theoretical atomic distribution, which must conform with a unit cell of 52 atoms.

Table 2

Designation	α	β	γ	γ_1	γ_2	ε	ζ'	η
Electron/atom ratio = Ve/A	1/1	3/2	5/3	7/4	9/5	11/6	13/7	2/1
Empirical formula	Cu	Cu_3Al	Cu_2Al	Cu_5Al_3	Cu_3Al_2	Cu_7Al_5	Cu_4Al_3	CuAl
Atomic % Al	0	25	33·3	37·5	40	41·7	42·9	50
True limits of phase field	0 20	25 approx.	31·5 35·2	35·4 38·0	38·3 40·2	Inc.		less than 50
Crystal structure	f.c.c.	b.c.c.	type	Deformed 'γ'		Related to γ		
Structural formula	Cu	Cu_3Al	Cu_9Al_4 $Cu_{17}Al_9$	$Cu_{32}Al_{19}$	$Cu_{30}Al_{20}$			
Space group			$P\bar{4}3m$	Cm	$R3m$			

For this reason, Cu_5Zn_8 and Cu_9Al_4 are preferred to the empirical formulæ, giving in both instances the somewhat lower ratio $Ve/A = 21/13$ (1·615 instead of 1·667).

However, the exact composition for Cu_9Al_4 is a two-phase alloy ($\alpha + \gamma$), showing that the crystal structure is not a decisive factor in fixing the phase boundaries. According to Konobeevsky[6], the exact upper limit for the γ-phase at $Cu_{17}Al_9$ corresponds to the complete filling of the first Brillouin zone, which is limited by the crystallographic planes (330) and (411). It is interesting to note that the approximate upper limit for γ-brass also agrees with a ratio $Ve/A = 22/13$, the appropriate formula being Cu_4Zn_9. Thus we have in addition to the empirical formulæ ($CuZn_2$ and Cu_2Al) both upper and lower limiting values for the phases. The corresponding formulæ (Cu_5Zn_8—Cu_4Zn_9 and Cu_9Al_4—$Cu_{17}Al_9$) indicate that the ratio Ve/A lies between 21/13 and 22/13.

Conclusion. There is a tendency for many alloy phases to occur when the ratio of the number of free valency electrons agrees with the monotonic sequence $(2n - 1)/n$, where $n = 1, 2, 3, 4, 5, 6, 7$. The characteristic ratio for the γ-phases would then be 5/3 instead of 21/13, although the crystal structures of Cu_5Zn_8 and Cu_9Al_4 require the latter value, while the upper limiting compositions Cu_4Zn_9 and $Cu_{17}Al_9$ point to the higher value 22/13. A publication will appear shortly to show why the ratios 21/13 and 22/13 are so very important.

Flow of Adsorbed Molecules

JUST as Knudsen and others[1] have shown for single capillaries, flow of a gas through a porous medium also undergoes a transition from viscous flow to molecular flow when pore diameters become comparable in size with the mean free path of the gaseous molecules. The position has been reviewed recently[2], but more data in the molecular flow region are desirable. I have therefore been studying the flow of various gases through plugs of 'Linde silica', a finely divided, amorphous silica stated by the makers to have a maximum particle size of 0·05 μ. The experiments cited here were carried out on a single plug compressed to a porosity (ε) of 0·678. The specific surface, S_0, calculated from the permeability equation of Carman and Arnell[2], was $2·35 \times 10^6$ cm.²/cm.³. This gives an equivalent pore diameter $\frac{4\varepsilon}{(1-\varepsilon)S_0} = 3·6 \times 10^{-6}$ cm., which was usually well below the mean free path of the various gases studied. Application of the Brunauer–Emmett–Teller calculation[3] to gas adsorption isotherms gave $S_0 = 2·8 \times 10^6$ to $4·1 \times 10^6$ cm.²/cm.³, indicating that particles possibly possess an internal surface which is not accessible to flow. To cover a wide range of molecular weights, flow-rates were measured at 22° C. for hydrogen, air, carbon dioxide and 'Freon-12', CF_2Cl_2, all of which gave consistent values for S_0.

The flow-rate for sulphur dioxide, however, was distinctly higher than expected. The boiling point of sulphur dioxide is such that it is appreciably adsorbed at 22° C., and it was suspected that this might be responsible. Further experiments were therefore carried out at 0° C., and the results, summarized in the accompanying table, seem to show clearly that the difference between observed permeabilities and those calculated on the assumption that $S_0 = 2·35 \times 10^6$ cm.²/cm.³ does depend on adsorption. Permeabilities are given by $pQL/A\Delta p$, where Q is rate of flow in cm.³/sec., measured at the mean pressure $p = (p_1 + p_2)/2$, at the temperature of the plug, L cm. and A cm.² are length and cross-section of the plug, and Δp is pressure difference across it. The pressure, p_1, on one side of the plug, was always atmospheric (about 660 mm. at Pretoria), while p_2 was varied and could be either greater or smaller than p_1. Adsorption was also measured, and has been expressed as v cm.³ of liquid sulphur dioxide adsorbed per cm.³ of plug, assuming density of adsorbed sulphur dioxide is equal to that of the liquid in bulk, that is, it gives the pore-space occupied by liquid sulphur dioxide. The value in brackets for $p_2 = 1{,}160$ cm. at 0° C. is assumed, on the basis that the pore-space is filled by condensed sulphur dioxide. At $p_1 = 660$ mm., corresponding values for adsorption are 0·039 at 22° C. and 0·072 at 0° C. From these, the values $\Delta v/\Delta p$ have been calculated in the last column of the table.

Temperatures (° C.)	p_2 (mm.)	Calculated permeability × 10³	Observed permeability × 10³	Pore space occupied by adsorbed SO_2 at p_2	$\frac{\Delta v}{\Delta p} \times 10^5$
22	83	1·17	1·40	0·012	4·7
22	1331	1·25	1·47	0·064	3·9
0	44	1·13	1·52	0·013	9·6
0	90	1·14	1·54	0·020	8·8
0	896	1·19	1·77	0·108	15·2
0	935	1·19	1·88	0·118	17·0
0	1067	1·20	2·16	0·234	40·2
0	1160	1·21	4·28	(0·68)	(121)
0	1300	1·22	1·57	—	—

The most remarkable feature is the extremely rapid increase in permeability at 0° C. as the saturation vapour pressure of liquid sulphur dioxide, 1,161 mm., is approached; especially since one would expect the volume occupied by adsorbed sulphur dioxide to restrict flow in the gas phase. Presumably, the reason is that the concentration gradient in the adsorbed film increases much more quickly than the pressure drop across the plug in this region, as shown by $\Delta v/\Delta p$.

The mobility observed for the adsorbed layer could not be predicted from the properties of liquid sulphur dioxide. If pores were wholly filled with the liquid, and the permeability is calculated from its viscosity, it is found to be of the order of 5×10^{-4} times the calculated gaseous permeability, that is, liquid sulphur dioxide should block the pore-space. Evidence favouring this is that, when $p_2 = 1,300$ mm., the initial permeability is still faster than for $p_2 = 1,160$ mm., but decreases steadily over many hours to the relatively low value cited. Presumably, the high-pressure side of the plug becomes choked with condensed sulphur dioxide, which evaporates as it flows to the low-pressure side.

These observations bear out those of Tomlinson and Flood[4], who studied the flow of diethyl ether and ethyl chloride vapours through rods of activated charcoal. These workers did not observe the rapid increase of permeability near the saturation pressure of the vapours, but did note that the difference between observed and calculated permeabilities increased at low values of the mean pressure. This is not unreasonable, since the gradient of an isotherm adsorption, that is, $\Delta v/\Delta p$, becomes considerably steeper at low relative pressures.

Further experiment has shown that other gases show qualitatively similar behaviour. For example, at 22° C., CF_2Cl_2 (b.p. − 33° C. at Pretoria) gives a permeability in agreement with calculation; at 0° C., it behaves like sulphur dioxide at 22° C.; at − 25° C., it shows the same large increase of permeability as p_2 approaches the saturation vapour pressure, and a slow approach to a relatively small permeability when p_2 exceeds this. It is hoped to publish a fuller account of these data elsewhere.

Daily Magnetic Variations near the Equators

THE establishment of the observatory at Huancayo, Peru, near the magnetic equator, led to the discovery of daily magnetic variations, both solar and lunar, approximately twice as great as those previously found in other tropical regions. McNish[1] has sought to explain this anomaly by qualitatively modifying the Balfour Stewart – Schuster 'dynamo' theory to allow for the non-coincidence of the earth's magnetic and geographic axes. According to McNish, enhanced magnetic variations should occur in the areas between the magnetic and geographic equators. On the other hand, Egedal[2] and Chapman[3] have recently put forward data from tropical regions which appear to show that the distribution of the phenomenon is more complex than could be explained by McNish's suggestion.

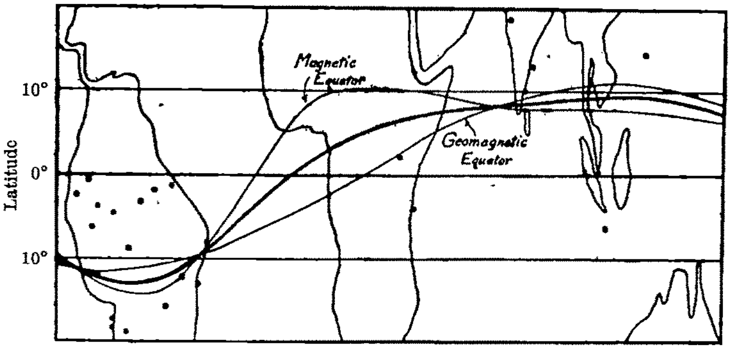

Fig. 1. Distribution of equatorial locations studied by Egedal and Chapman for anomalous magnetic variations. The heavy line is midway between the magnetic and geomagnetic equators

Now in 1908 Schuster[4] himself gave a quantitative account of the modifications introduced into the 'dynamo' theory by the non-coincidence of the earth's magnetic and geographic axes. It is easy to show that this produces symmetry of the variations about an equator which lies between the magnetic and true equators: the variations should show a shallow maximum at this 'magneto-dynamic' equator. McNish's qualitative arguments agree with Schuster's and lead to a small increase of the magnetic variations in the regions he specified: they cannot account for the very large increases found.

It is of interest to investigate whether the data examined by Egedal and Chapman show a symmetrical distribution of the anomaly about an equator. (The distribution of the sites examined by these authors

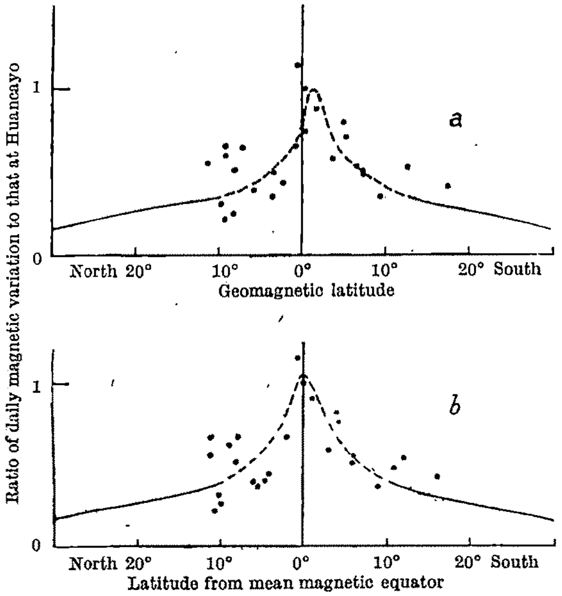

Fig. 2. Amplitude of daily magnetic variations plotted against (*a*) geomagnetic latitude, (*b*) latitude measured from a mean magnetic equator

is shown in Fig. 1.) The large variation revealed by Chapman for Uganda, which is not close to the *magnetic* equator (that of zero inclination), indicates that the latter is not the line of maximum anomaly.

The magnitude of the variations is plotted against *geomagnetic* latitude in Fig. 2*a*. (This latitude is measured from the equator of the earth's dipole axis.) It will be seen that the distribution is not symmetrical about this equator. In Fig. 2*b* the magnitude is plotted against latitude measured from an equator which is midway between the magnetic and geomagnetic equators. In this case approximate symmetry is obtained.

It would seem, therefore, that the observed anomalies require the existence in the ionosphere of a narrow region of high electric *conductivity* (about 15° of latitude wide) encircling the world approximately mid-way between the magnetic and geomagnetic equators.

This work is published by permission of the Radio Research Board of the Council for Scientific and Industrial Research.

Emission Spectrum Attributed to Cadmium Fluoride

EMISSION bands attributed to cadmium fluoride by Asundi, Samuel and Zaki-Uddin[1] have been shown by Pearse and Gaydon[2] to be due to calcium fluoride. In their work, Pearse and Gaydon found six diffuse, band-like structures, three degraded to the red and three to the violet, in the spectrum of a cadmium arc fed with cadmium fluoride. These structures were tentatively ascribed to cadmium fluoride. Howell[3] gave reasons for believing that they are indeed due to cadmium fluoride, and arranged them into two band systems. However, the absorption spectrum of cadmium fluoride was investigated by Fowler[4] and nothing found corresponding to these emission bands; though, of course, it is quite possible for bands observed in emission to be missing in absorption and *vice versa*. Nevertheless, a new investigation of the emission spectrum was felt to be desirable.

Experiments were made with flames and arcs containing cadmium fluoride; but it was not found possible to excite in emission any of the bands that had been attributed to cadmium fluoride in absorption. It was found, however, that the six diffuse structures could be excited in the arc between cadmium metal electrodes without the presence of fluoride, and that the structures disappeared as the arc chamber was evacuated. This led to their identification with lines listed in Fowler's "Report"[5] (see table).

The lines are all of the combination type, strictly forbidden by elementary selection rules. Three of the lines, λλ 2961·48, 2862·30, 2818·73, which form the multiplet $5s5p\ {}^3P^0{}_{0,1,2} - 5s4f\ {}^3F^0{}_{2,3,4}$ have been studied in detail by Ornstein and Burger[6], who conclude that the radiation is of the electrical dipole type forced by ionic electric fields. This conclusion is supported by the observations of Fukuda, Kayama and Uchida[7] on the excitation of all six of the lines in a high-current arc and also by Fujioka's study of their Stark effect[8]. The great asymmetry of the lines is brought about by the perturbation of the atomic energy-levels by the ionic fields forcing the radiation.

'CdF bands'			Cd lines		
λ(A)	I		λ(A)	I	
3005	(5)	R	3005·41	(1)	r
2961·5	(5)	V	2961·48	(4)	v
2908	(2)	R	2908·74	(1)	r
2904	(1)	R	2903·13	(1)	n
2862	(5)	V	2862·30	(2)	v
2819	(3)	V	2818·73	(1)	v

R = band degraded to red
V = band degraded to violet
r = line shaded to red
v = line shaded to violet
n = diffuse line

It is now well known that in certain circumstances bands may be mistaken for lines. This example shows that it is also necessary to beware of lines that may be mistaken for bands.

Magnetic Polarizability of the Electron

THE anomaly of the magnetic moment of the electron has been explained by Schwinger[1] as due to the interaction of the electron with the zero-point fluctuations of the radiation field. A particularly simple derivation has recently been given by Luttinger[2]. Luttinger considers the state of an electron in a constant magnetic field H such that its energy is exactly equal to mc^2, the energy of the orbital magnetic moment cancelling the energy of the spin magnetic moment. He then calculates the self-energy of the electron in this state due to the interaction with radiation, and expands this in powers of H. The term independent of H is divergent, being the well-known self-energy of the electron in the absence of any field, while the term proportional to H is finite and given by ($\hbar = c = 1$):

$$E = -\frac{e^3H}{4\pi m}. \quad (1)$$

This gives the radiative correction to the magnetic moment of the electron in agreement with experiments. It will be of interest to investigate also the terms of higher powers in H, for example, that proportional to H^2, which represents a magnetic polarizability of the electron. It is important to ascertain whether all the intrinsic properties of the electron are finite, except the self-energy and self-charge, which are infinite. Since the electron has spin $\frac{1}{2}$, field-independent moments other than a magnetic moment cannot exist; but polarizabilities and higher induced moments exist. To calculate the magnetic polarizability it is necessary only to carry the expansion in H one step further. This we have done, and it is found that this term is convergent for large values of the momentum of the virtual photons but diverges logarithmically for low values. This divergence, however, is due to an unpermissible expansion in powers of H, as can be seen by summing up the divergent contribution of this term with other contributions occurring in the higher powers of H. The result is a term involving $H^2 \log H$. Thus we find for the contributions to the self-energy due to the static and dynamic interactions with the virtual photons:

$$\left.\begin{aligned} E_{\text{static}} &= -\frac{e^4H^2}{90\pi m^3} + O(H^3) \\ E_{\text{dynamic}} &= -\frac{e^4H^2}{4\pi m^3} - \frac{2e^4H^2}{3\pi m^3}\log\frac{2eH}{m^2} + O(H^3) \end{aligned}\right\} \quad (2)$$

This result is finite, and it is quite easy to see that the terms proportional to higher powers of H are also finite. Owing to the logarithmic dependence on H, strictly speaking it is not correct to call (2) the 'magnetic polarizability', but this is of little importance. (2) is still smaller than (1) by a factor of the order $\frac{\mu_0 H}{mc^2} \log \frac{mc^2}{\mu_0 H}$ (where μ_0 is the Bohr magneton), which makes the polarizability for all practical purposes far too small to be observed at present.

I wish to express my thanks to Prof. Heitler for suggesting this investigation, and for valuable discussions.

Analogue Calculating Machine for Functions of a Complex Variable

WE have recently been concerned with a physical analogue to assist in dealing with functions of the complex variable, z, of the class:

$$f(z) = \frac{a_n z^n + a_{n-1} z^{n-1} + a_{n-2} z^{n-2} \ldots a_0}{b_m z^m + b_{m-1} z^{m-1} + b_{m-2} z^{m-2} \ldots b_0}$$

$$m \sim n = 1;\ a_n\ b_m \text{ real.} \quad (1)$$

This analogue device has many applications to electric network analysis and synthesis, and to other vibration problems; however, its capabilities would appear to be of sufficiently broad mathematical interest to warrant more general attention.

Such functions satisfy Laplace's equation $\nabla^2 f(z) = 0$, except at the singularities, and so may represent two-dimensional physical potential fields, for example, (*a*) an electrostatic field, (*b*) a stretched membrane, (*c*) a current-carrying conducting sheet, etc., with the singularities represented respectively by point charges, point displacements and point current sources. The system (*c*) has been found particularly suitable, using a shallow layer of electrolyte and by taking certain precautions to eliminate the boundary error[1], so that the electrolyte surface represents the infinite z-plane and includes an accessible 'infinity' point. A fine point electrode, carrying a constant current, placed at the point z_r, sets up a potential at any other point z proportional to $\log |(z-z_r)|$ and a potential gradient represented in both magnitude and direction by the conjugate of $(z - z_r)^{-1}$, both of which may be measured electrically. These properties form the basis of the analogue, which is applied in two different ways.

In the first application, the real, imaginary or complex zeros of either the numerator or denominator of (1) may be found, by exploring the potential gradient over the electrolyte surface set up by suitably placed electrodes, in order to locate the points of zero gradient. Furthermore, the case of complex coefficients, $a_n, \ldots b_n, \ldots$ etc., may also be dealt with[2].

Secondly, if $f(z)$ be factorized by this method, it may be represented in logarithmic form:

$$\log f(z) = \sum_{z=1}^{n} \log (z - z_z) - \sum_{p=1}^{m} \log (z - z_p), \quad (2)$$

by electrodes placed at the zeros z_z and poles z_p carrying currents proportional to their multiplicity (if multiple singularities are present). The potential over the electrolyte surface determines the modulus of $\log f(z)$, and, further, it may be shown that its argument is represented by the summation, along a line parallel to the imaginary axis, of the potential gradients (parallel to the real axis) between z and the real axis. This modulus and argument measurement, especially along the imaginary axis, has been reported previously.

Thirdly, with $\log f(z)$ thus represented, the residues at the simple poles of $f(z)$, which are in general complex, may be measured. The residue ν_p at a pole z_p is the value of $f(z) \, . \, (z-z_p)$ at $z = z_p$; this may be measured physically by removing the electrode at z_p and measuring $\log f(z)_{z=z_p}$ as explained above. A somewhat more complicated process enables the residues at double or triple poles to be determined. Knowledge of all the residues enables the inverse Laplace transform of $f(z)$ to be constructed.

Calculations can also be carried out on functions of other types; in general, any regular function satisfies Laplace's equation and is capable of similar physical interpretation, though not always by using point electrodes only. For example, a branch cut may be simulated by a strip, made of conducting or insulating material, depending upon the type of discontinuity possessed by the function, placed in the electrolyte.

Measurement of Diversity

THE 'characteristic' defined by Yule[1] and the 'index of diversity' defined by Fisher[2] are two measures of the degree of concentration or diversity achieved when the individuals of a population are classified into groups. Both are defined as statistics to be calculated from sample data and not in terms of population constants. The index of diversity has so far been used chiefly with the logarithmic distribution. It cannot be used everywhere, as it does not always give values which are independent of sample size; it cannot do so, for example, when applied to an infinite population of individuals classified into a finite number of groups. Williams[3] has pointed out a relationship between the characteristic and the index of diversity when both are applied to a logarithmic distribution. The present purpose is to define and examine a measure of concentration in terms of population constants.

Consider an infinite population such that each individual belongs to one of Z groups, and let $\pi_1 \ldots \pi_Z$ ($\Sigma\pi = 1$) be the proportions of individuals in the various groups. Then λ defined as $\Sigma\pi^2$ is a measure of the concentration of the classification. It can take any value between $1/Z$ and 1, the former representing the smallest concentration or largest diversity possible with Z groups, and the latter complete concentration, all the individuals being in a single group. λ can be simply interpreted as the probability that two individuals chosen at random and independently from the population will be found to belong to the same group.

Now suppose a sample of N individuals to be chosen at random from a population of this kind, and let $n_1, n_2 \ldots n_Z$ ($\Sigma n = N$) be the numbers of individuals falling into the various groups. It is easily shown that $l = \dfrac{\Sigma n(n-1)}{N(N-1)}$ is an unbiased estimator of λ; this is almost obvious since $\frac{1}{2}N(N-1)$ is the number of pairs in the sample and $\frac{1}{2}\Sigma n(n-1)$ is the number of pairs drawn from the same group.

l is also an unbiased estimate of λ when the sample-size varies, provided no samples of size 0 or 1 are included and that the probability of the sample $(n_1, n_2 \ldots n_Z)$ splits into these two factors:

$$P(n_1, n_2 \ldots n_Z) = P(N) \frac{N\,!}{n_1\,!\; n_2\,! \ldots} (\pi_1)^{n_1} (\pi_2)^{n_2} \ldots,$$

where $P(N)$ gives the probability distribution of the sample size, $2 \leqslant N \leqslant \infty$. This is true in particular when samples are obtained by the 'fixed-exposure' method common in biological work, N having then a Poisson distribution adjusted for the absence of the first two terms.

If repeated samples of size N are drawn from the same population, the values of l obtained will be distributed about λ with variance

$$\frac{4N(N-1)(N-2)\,\Sigma\pi^3 + 2N(N-1)\,\Sigma\pi^2 - 2N(N-1)\,(2N-3)\,(\Sigma\pi^2)^2}{[N(N-1)]^2},$$

or, if N be very large, approximately

$$\frac{4}{N}\,[\Sigma\pi^3 - (\Sigma\pi^2)^2].$$

The third and fourth cumulants of the distribution of l have also been calculated exactly. They indicate that as N increases, the distribution tends to normality except when $\lambda = 1/Z$; in that case the distribution of lNZ tends to that of χ^2 with $Z - 1$ degrees of freedom, but with its mean moved from $Z - 1$ to N.

The characteristic defined by Yule[1] is, in the notation used above, $1{,}000\ \Sigma n(n-1)/N^2$, which differs from l, the sample estimator of λ, only in having N instead of $N - 1$ in the denominator and in the scale factor of 1,000.

Now let us see what value λ takes for a population containing Z groups the frequencies of which are $\pi_i = w_i/\Sigma w$, where the w_i are chosen at random and independently from the Type III distribution

$$dF = \frac{1}{(k-1)\,!}\, e^{-w}\, w^{k-1}\, dw, \qquad 0 \leqslant w \leqslant \infty.$$

This may be called a 'negative binomial population', since samples drawn from it by the 'fixed exposure' method will obey the negative binomial distribution. The value of λ appropriate to it is obtained by averaging $\Sigma w_i^2/(\Sigma w_i)^2$ over all sets $(w_1, w_2 \ldots w_Z)$ which can be drawn from the population of values of w. Thus

$$\lambda = \int_0^\infty \cdots \int_0^\infty \left[\frac{1}{(k-1)\,!}\right]^Z e^{-\Sigma w}\, [w_1 \ldots w_z']^{k-1}\, \frac{\Sigma w_i^2}{(\Sigma w_i)^2}\, dw_1 \ldots dw_Z = \frac{k+1}{Zk+1}.$$

The Poisson distribution is the special case of the negative binomial distribution in which k tends to infinity. Under this condition, $\lambda = 1/Z$. This is as we would expect, since the Poisson distribution arises from a population in which all groups are equally represented, and so the probability that two individuals chosen at random will be found to belong to the same group must be $1/Z$.

The other extreme case of the negative binomial is the logarithmic population, which is obtained by letting Z tend to infinity and k tend to zero simultaneously so that the product Zk remains finite and tends to a quantity called α. (This is not quite the same derivation as that used by Fisher[2], but the quantity α is the same as his index of diversity.) The value obtained for λ under this limiting process is $1/(\alpha + 1)$.

It will be noticed that this last value is not consistent with the equation given by Williams[3], namely, that Yule's characteristic had the value $1{,}000/\alpha$ when applied to the logarithmic distribution. His result was obtained by applying Yule's formula to a series of expected values, whereas the present procedure is equivalent to applying the formula first and then averaging the result. Some support for the new equation is found by considering the ranges of the variables concerned. Since the characteristic cannot exceed 1,000, the earlier equation would deny to α all values less than 1; but the present one allows it the range $0 \leqslant \alpha \leqslant \infty$, while $1 \geqslant \lambda \geqslant 0$.

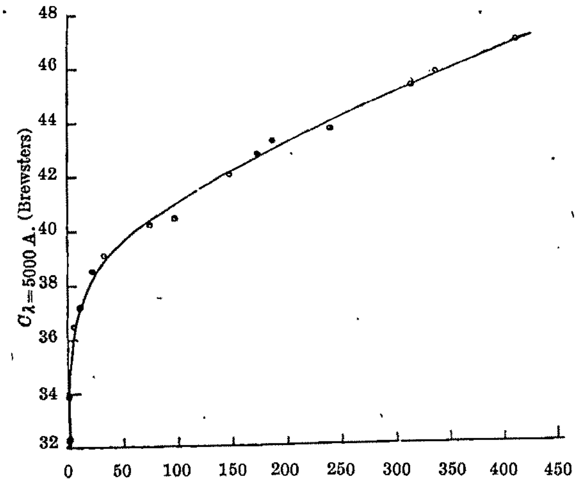
Photo-elastic Creep in 'Catalin 800' and *CR* 39

DURING the course of an investigation on the variation with wave-length λ of the stress-optic coefficient C_λ of 'Catalin 800' (a glass-clear phenol-formaldehyde resin) and of *CR* 39 (a condensed allyl ester), it has been found that C_λ depends upon the time allowed to elapse between the application of the load and the measurement of the resultant birefringence, the effect being due to the so-called photo-elastic creep in the loaded specimens. The two specimens, one of 'Catalin' and the other of *CR* 39, were both strained by a tensile force applied by a simple loading machine working on the lever principle, and the stress-optic coefficients were determined by the modified form of Filon's method[1], using a spectrograph instead of the usual spectrometer.



O—O—, Experimental points; curve computed from $C_\lambda = c_0' + c_1' \{1 - \exp(-kt^{1/3})\} + c_2't$

From the spectrogram formed by plane-polarized parallel light which has passed through a narrow limited section of the strained specimen, C_λ for a given wave-length can be deduced. From a series of such spectrograms, taken at intervals of time, t, after loading, values of C_λ for $\lambda = 5000$ A. were calculated, and plotted against t. Equations were itted to the curves.

For 'Catalin' the results agree with those of Mylonas[2], the relation between C_λ and t being

$$C_\lambda = c_0 + c_1 t^{0\cdot 3}, \qquad (1)$$

where c_0 and c_1 are constants. The maximum duration of the test was 24 hours, though Mylonas, who originally suggested (1), used tests of duration less than one hour. For periods of continuous loading up to one hour, the experimental results agree with 1) to within 1 per cent, and for periods of 24 hours to within 5 per cent. c_0 and c_1 vary considerably from test to test, appearing to depend upon the history of the specimen. (A similar effect has been observed by previous investigators but for other materials.) Since the same value of load was used hroughout, the dependence, if any, of c_0 and c_1 on he stress could not be ascertained.

For *CR* 39 more detailed results were obtained, but, as for 'Catalin', for one value of load only. The 'creep'-rate was not as rapid as for 'Catalin'. For short-period loadings, C_λ and t are related exponentially, but for long-period loading (over a range of 400 hr.) a better fit to the experimental results is given by

$$C_\lambda = c_0' + c_1' [1 - \exp(-kt^{1/3})] + c_2't \qquad (2a)$$

for $\lambda = 5000$ A., where c_0', c_1' and c_2' are constants and t is in hours; k is numerically of the order of 0·32. After 450 hours, the observed values of C_λ were less than those given by (2a), and it is probable that the linear term $c_2't$ should be replaced then by another exponential term. For short-period loading it is clear that (2a) reduces to

$$C_\lambda = c_0' + c_1' [1 - \exp(-kt^{1/3})], \qquad (2b)$$

since c_0', c_1' and c_2' are of the order of 30 and 9 Brewsters, and 0·015 Brewsters per hour respectively. It is interesting to note that a relationship of the form of (2b) was originally suggested by Pierce[3] in connexion with the variation of the torsion of a cotton thread with time.

In the past, investigators have found a similarity between optical and mechanical 'creep' behaviours in various materials. A brief check of the mechanical 'creep' properties of 'Catalin' or *CR* 39, by measuring the deflexions of beams of the two materials when subjected to a constant bending moment, was made. Relations approximately analogous to those of (1) and (2b) were obtained.

Amino-Acid Composition of Salmine

A DETAILED chemical analysis of the amino-acid composition of salmine (from a commercial source) was presented by Block and Bolling[1], who used chemical and microbiological techniques. The amino-acids found were arginine, alanine, *iso*leucine, proline, serine and valine. Tristram[2] confirmed the presence of these, and in addition demonstrated that glycine was also a constituent.

In the course of other work, analyses have been made in this Laboratory of hydrolysed salmine (commercial) by partition chromatography on paper. The 'ascending' modification of the original method was used[3]. We thought it of interest to report that our results confirmed those of Tristram. No other amino-acids were detected using one- or two-dimensional chromatograms when phenol with ammonia, collidine–lutidine mixture 1 : 1 (v/v), or *n*-butanol–acetic acid mixture 4 : 1 (v/v), were used as solvents.

An estimate of the proportions of amino-acids present has been made by the spot-dilution technique[4]. The results are presented in the accompanying table.

	Amino-acid per 100 gm. salmine		
Amino-acid	Authors	Tristram	Block
Arginine	87·5	85·2	88·4
Alanine	0·6	1·10	3·6
Glycine	3·6	2·94	—
*iso*Leucine	1·8	1·61	1·5
Proline	5·0	5·8	7·9
Serine	5·6	9·1	7·0
Valine	3·8	3·1	4·1

The proportions found were in fair agreement with those of the earlier workers; but appreciably lower values were obtained for the amounts of alanine and serine. The hydrolysis was carried out by heating the salmine in a sealed tube with 5N hydrochloric acid for 40 hr. at 90° C. The low values observed in the case of alanine and serine do not appear to be attributable either to incomplete hydrolysis or to destruction during digestion, because (*a*) the results were not altered by considerably longer periods of hydrolysis, and (*b*) chromatograms of a mixture of the seven amino-acids before and after treatment, under the conditions of the hydrolysis, showed no detectable destruction of any component.

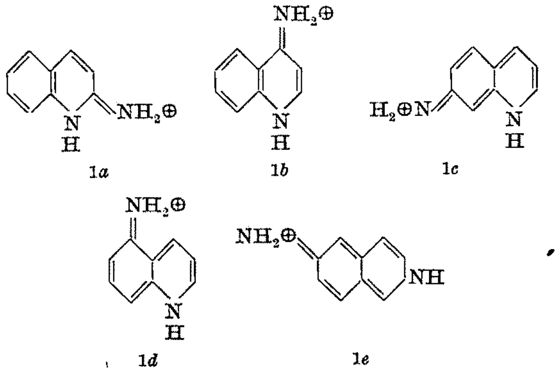
Base-Strengthening Effect of Resonant Amino Groups in some Heterocyclic Bases

IT was shown by Albert and Goldacre[1] that an amino group substituted in a 'resonant position' of a six-membered aromatic heterocyclic base results in a compound of enhanced basic strength. This is attributed to the replacement of a dipolar resonant form by a more stable homopolar resonant form.

The ionic quinonoidal structures discussed by Albert and Goldacre[1] fall into four groups: (1) an *ortho*-quinonoid structure, as represented by 2-amino quinoline (Fig. 1*a*); (2) a *para*-quinonoid structure, as represented by 4-amino quinoline (Fig. 1*b*); (3) an *ortho-para*-quinonoid structure, as represented by 7-amino quinoline (Fig. 1*c*); (4) an *ortho-ortho*-quinonoid structure, as represented by 5-amino quinoline (Fig. 1*d*). A fifth possibility, that of a *para-para*-quinonoid structure, was not considered by them. The simplest example of this type would be 6-amino *iso*quinoline (Fig. 1*e*).



1*a* 1*b* 1*c* 1*d* 1*e*

Fig. 1

It seemed of interest to determine the base-strengthening effect (ΔpK_A) of such a *para-para*-quinonoid structure, in order that a comparison of the relative stabilities of the above five structures can be made. For this purpose 2-amino benzcinnoline (Fig. 2) was chosen, 6-amino *iso*quinoline being unavailable.

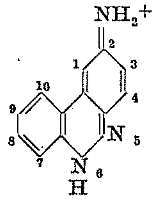


Fig. 2

The pK_A of benzcinnoline and of its 2-amino derivative was determined, in water by the colorimetric method described by Albert and Goldacre[2], and in 50 per cent ethanol by potentiometric titration (glass-electrode). The results are expressed in Table 1.

Table 1

	Water		50% ethanol	
	Conc.	pK_A (20°)	Conc.	pK_A (20°)
Benzcinnoline	0·0002 M	2·20 ± 0·05	0·05 M	1·6 ± 0·2
2-Amino benzcinnoline	0·0002 M	6·68 ± 0·05	0·006 M	6·23 ± 0·05
ΔpK_A		4·48 ± 0·1		4·6 ± 0·2

The base-strengthening effects of amino groups substituted in those positions associated with quinonoidal resonances of the above five types, measured in water, are listed in Table 2.

Table 2. ΔpK_A effects* of quinonoidal resonances

Nucleus	Quinonoidal structure				
	ortho-	*para-*	*ortho-para-*	*ortho-ortho-*	*para-para-*
Pyridine	1·63	3·94	—	—	—
Quinoline	2·40	4·23	1·71	0·52	—
*iso*Quinoline	2·29	—			
Acridine	—	4·39	2·44	0·44	—
3 : 4-Benzacridine	—		2·72		—
Pyridazine	2·86		—	—	—
Pyrimidine	2·24	4·41	—	—	—
Pyrazine	2·54	—	—	—	—
Cinnoline	—	4·14			
Phthalazine	3·13	—		—	
Quinazoline	0·92†	2·22†			
Quinoxaline	3·16	—			—
3 : 4-Benzcinnoline	—	—			4·48

* Values (water) calculated from Albert, Goldacre and Phillips[3].
† The anomalous values for quinazoline will be discussed in a futur note by one of us (J. N. P.).

From Table 2 it can be seen that the ΔpK associated with any particular quinonoidal structur is reasonably constant for several heterocyclic nucle (It is interesting to note, in view of the great differences in water solubility of the compounds in Tabl 2, that solvation seems to play only a minor part. The constancy of pK_A suggests that the resonanc energy of such a structure is the predominant facto in determining the basic strength. The relativ stability of the five structures is seen to be

para- and *para-para-* > *ortho-* and *ortho-para-* > *ortho-ortho-*.

Since the presence of fused benzene rings does no appreciably influence the ΔpK_A, then from the abov postulate that a *para-para*-quinonoid is of the sam order of stability as a *para*-quinonoid structure, i would follow that a *para*-quinonoid and an isolate Kekulé structure are of approximate total energ equivalence. The fact that the *ortho-* and *ortho-para* quinonoid types show the same order of stabilit supports this conclusion. It can similarly be reasone that an *ortho*-quinonoid structure is of greater tot energy (less stability) than an isolated Kekulé structure.

The figures in Table 2 enable one to predict approximate pK_A values (in water) for bases giving rise to ionic forms of the above five types. ΔpK_A values (averaged from Table 2) would be *ortho* = + 2·5, *para* = + 4·2, *ortho-para* = + 2·3, *ortho-ortho* = + 0·5, *para-para* = + 4·5.

In this way, from the pK_A values of *iso*quinoline (5·33, water), phthalazine (3·47, water) and phenanthridine (3·30, 50 per cent ethanol), the pK_A values of 6-amino *iso*quinoline, 6-amino phthalazine and 6-amino phenanthridine may be predicted to be 9·8 (water), 8·0 (water) and 7·9 (50 per cent ethanol; see Table 1 for ΔpK_A), respectively. These three bases (*para-para*-quinonoid type) would be the strongest mono-amino derivatives in their series, since in each case no amino derivative of the *para*-quinonoid type is possible.

One of us (P. H. G.) thanks the Commonwealth Research Grant Committee of this University for a scholarship.

Reaction between Hydrogen Peroxide and Iron Salts

FROM a recent discussion with J. H. Baxendale and P. George, we understand that they have from kinetic studies proposed a reaction scheme for the mechanism of the evolution of oxygen from hydrogen peroxide and ferrous ions [see p. 692 of this issue of *Nature*]. We have also obtained experimental evidence from the studies of the consumption ratios which lead to conclusions similar to theirs and which are discussed in the following.

The reaction between hydrogen peroxide and ferrous salts has been studied by Haber and Weiss[1] and certain aspects of it more recently again by Baxendale, Evans and Park[2]. We have now studied this reaction in its dependence on *p*H, and we have investigated the role of the ferric ions in the hydrogen peroxide ferrous-ion reaction.

We have used a flow apparatus built on similar lines to those suggested by Schmid[3], to bring about a very rapid mixing of the component solutions and thus to ensure well-defined initial concentrations of the reactants. So far, only consumption ratios $(-\Delta(H_2O_2)/-\Delta(Fe^{II}))$ have been measured.

In order to study the effect of ferric ions, we have investigated the reaction (at different *p*H) in the presence of (i) fluoride, (ii) pyrophosphate ions, both of which are known to form stable complexes with ferric ions, and we have convinced ourselves that these complexes are not active as catalysts. We have found that fluoride and pyrophosphate ions both decrease the consumption ratios.

It is of importance to note that the hydrolysis products of ferric ions (which are formed if the reaction is carried out at sufficiently high *p*H) are themselves also practically inactive as catalysts during time intervals which are relevant for the relatively fast reaction between ferrous ions and hydrogen peroxide.

Conversely, we have been able to show that addition of ferric salts (over and above that formed by the oxidation of the ferrous salt) increases the consumption ratios. This clearly indicates that ferric ions are involved in the ferrous ion catalysis, which, however, must not be confused with the well-known relatively slow catalytic decomposition of hydrogen peroxide by ferric salt alone.

It seems that all this can be explained by a slight modification of the original scheme of Haber and Weiss by introducing into the 'ferrous ion catalysis' one of the reactions (reaction (14) of ref. 1) which has been considered previously in connexion with the 'ferric ion catalysis'.

The decrease of the consumption ratios with decreasing *p*H suggests further that it is the anion, O_2^-, rather than the undissociated HO_2 which enters into the reaction, the two being connected by the equilibrium $HO_2 \rightleftharpoons H^+ + O_2^-$.

Thus in addition to the original equations:

$$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + OH^- + OH \ldots (1)$$

$$H_2O_2 + OH \rightarrow H_2O + HO_2 \ldots\ldots\ldots\ldots (2)$$

$$H_2O_2 + HO_2 \rightarrow O_2 + H_2O + OH \ldots\ldots (3)$$

$$Fe^{2+} + OH \rightarrow Fe^{3+} + OH^- \ldots\ldots\ldots\ldots (4)$$

with a possible additional chain-breaking by the interaction of two radicals, for example:

$$HO_2 + OH \rightarrow O_2 + H_2O, \ldots\ldots\ldots (5)$$

one has the oxygen-producing reaction:

$$Fe^{3+} + O_2^- \rightarrow Fe^{2+} + O_2; \ldots\ldots (6)$$

which reaction, in the presence of ferric ions, largely replaces reaction (3); this, on the other hand, is of fundamental importance in the photochemical decomposition[4] and in the decomposition of hydrogen peroxide by ionizing radiations[5].

Reaction (6) is also of great importance in the aerobic oxidation of ferrous ions, as discussed previously[6].

If, on the other hand, one starts with ferric ions only, the initial reaction is represented by the well-known process[1]:

$$Fe^{3+} + HO_2^- \rightleftharpoons Fe^{2+} + HO_2 \ldots\ldots (7)$$

which, in conjunction with the oxygen-producing reaction (6) and followed by the re-oxidation of the ferrous ions according to reactions (1) and (4), gives a sufficiently complete picture of the 'ferric ion catalysis' of hydrogen peroxide as discussed in the earlier paper[1]. However, in general one has to include also the reverse process of reaction (7) and the chain reactions (2) and (3) as discussed previously.

Thus the only difference compared with the previous scheme is that reaction (6) preponderates over reaction (3) if ferric ions are present.

A full account with all the experimental details will be published elsewhere.

REACTIONS OF FERROUS AND FERRIC IONS WITH HYDROGEN PEROXIDE

By W. G. BARB, J. H. BAXENDALE, PHILIP GEORGE and K. R. HARGRAVE
Chemistry Department, University of Leeds

In the elucidation of the mechanism of the reactions between hydrogen peroxide and ferrous and ferric ions, a considerable advance was made by Haber and Weiss[1], who suggested that the highly reactive intermediates which have been shown to be present were the radicals $HO\cdot$ and HO_2. Their mechanisms, recently revised by Weiss[2], are as follows:

Fe^{2+} reaction

$$\begin{array}{llll} Fe^{2+} + H_2O_2 & \rightarrow Fe^{3+} & + OH^- & + HO. \\ H_2O_2 + HO\cdot & \rightarrow H_2O & + HO_2 & \\ H_2O_2 + HO_2 & \rightarrow O_2 & + H_2O & + HO. \\ Fe^{2+} + HO_2 & \rightarrow Fe^{3+} & + HO_2^- & \\ Fe^{2+} + HO\cdot & \rightarrow Fe^{3+} & + OH^- & \end{array}$$

Fe^{3+} reaction

$$\begin{array}{llll} H_2O_2 & \rightarrow H^+ & + HO_2^- & \\ Fe^{3+} + HO_2^- & \rightarrow Fe^{2+} & + HO_2 & \\ H_2O_2 + HO_2 & \rightarrow O_2 & + H_2O & + HO\cdot \\ Fe^{2+} + HO\cdot & \rightarrow Fe^{3+} & + OH^- & \\ OH^- + H^+ & \rightarrow H_2O & & \end{array}$$

The reaction with the ferrous ion is seen to involve chains with $HO\cdot$ and HO_2 as carriers; the ferric ion reaction consists of a sequence of radical reactions. In both cases oxygen is evolved by HO_2 reacting with hydrogen peroxide.

We have made an extensive experimental investigation which has revealed several new facts incompatible with the above scheme for the ferrous ion reaction. We conclude that the reaction producing oxygen is not that of HO_2 with hydrogen peroxide, but HO_2 or O_2^- with the ferric ion, and we propose a chain reaction involving HO_2, $HO\cdot$ and Fe^{2+} as carriers. The same chain mechanism will interpret satisfactorily both the ferrous and the ferric reactions.

The following is a summary of our observations on the ferrous ion reaction.

Ferrous Ion Reaction

It has previously been found that with low H_2O_2/Fe^{2+} ratios and in acid solutions the reaction is second order and the overall stoichiometry is $2Fe^{2+} \equiv H_2O_2$. When an excess of a polymerizable vinyl compound is present, the reaction is still second order in ferrous ion and hydrogen peroxide, but the stoichiometry changes to $Fe^{2+} \equiv H_2O_2$. Under these conditions polymerization occurs and the polymer has terminal hydroxyl groups. These observations are good evidence that the following reactions occur[3]:

$$\begin{array}{llll} Fe^{2+} + H_2O_2 & \rightarrow Fe^{3+} & + OH^- + HO\cdot & (o) \\ Fe^{2+} + HO\cdot & \rightarrow Fe^{3+} & + OH^- & (1) \\ M \quad + HO\cdot & \rightarrow HOM\cdot & \rightarrow \text{polymer} & \end{array}$$

In the absence of substrate the rate equation is

$$-d[Fe^{2+}]/dt = 2k_0[Fe^{2+}][H_2O_2].$$

However, although at low H_2O_2/Fe^{2+} ratios monomers are polymerized, leuco dyestuffs oxidized to the dye, and certain dyes destructively oxidized, thus confirming the presence of the radical HO, we have found that at the same concentrations of ferrous ion and substrate these reactions do not occur with high concentrations of hydrogen peroxide.

It is clear that under these conditions another competitor for $HO\cdot$ is present, and the observations can be explained if $HO\cdot$ reacts with hydrogen peroxide to give HO_2. The HO_2 radical thus formed is apparently unable to open the double bond of a vinyl compound or to oxidize the other substrates.

With high H_2O_2/Fe^{2+} ratios, oxygen is evolved on the addition of ferrous ion to hydrogen peroxide, which means that the stoichiometry is no longer $2Fe^{2+} \equiv H_2O_2$ and other reactions enter in addition to (o) and (1) above. The following results obtained in perchloric acid solutions from *p*H 1 to *p*H 3 enable the mechanism of reaction in this *p*H range to be deduced.

(1) *Ferrous Ion Kinetics.* With concentrations of ferrous ion of approximately 10^{-5} *M* and hydrogen peroxide less than 10^{-3} *M*, $d[Fe^{2+}]/dt$ can be measured by determining the concentration of ferrous ion, $[Fe^{2+}]$, colorimetrically with dipyridyl. Peroxide can be estimated by adding to excess acid Fe^{2+} or as pertitanic acid. Provided $2[Fe^{2+}] > [H_2O_2]$ initially, the reaction is second order throughout with $2Fe^{2+} \equiv H_2O_2$. This holds up to *p*H 3. At high H_2O_2/Fe^{2+} ratios the reaction initially follows the normal second-order course; but the 'rate constant' $k_{obs.}$ decreases as the reaction proceeds. This effect is shown in Fig. 1, curves (*a*) and (*b*), where the results are plotted as for a second-order reaction with hydrogen peroxide in great excess. Values of $k_{obs.}$ which are less than half that of the overall normal constant $2k_0$ are obtained. For a given

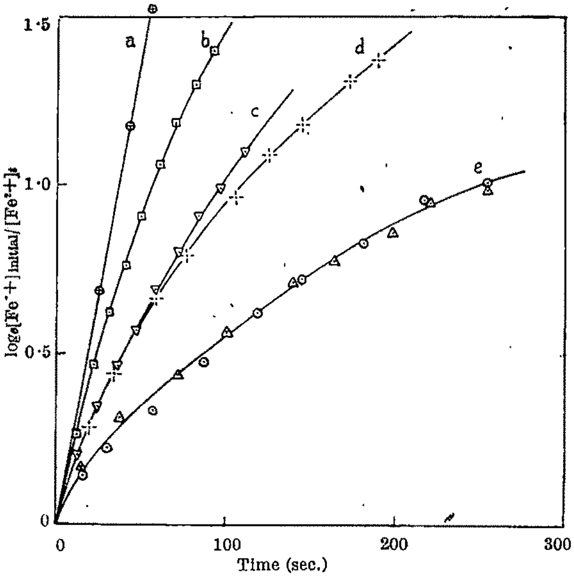

Fig. 1. Course of $Fe^{2+} + H_2O_2$ reaction with initial concentrations $1\cdot4 \times 10^{-5}$ Fe^{2+} and $29\cdot5 \times 10^{-5}$ *M* H_2O_2 at 25° C., and *p*H 2·65 except in (*a*). In no case is more than 10 per cent of the hydrogen peroxide used over the time interval shown. (*a*) *N*/2 $HClO_4$; (*b*) no additions; (*c*) initially $4\cdot6 \times 10^{-5}$ *M* Fe^{3+}; (*d*) initially $1\cdot4 \times 10^{-6}$ *M* Cu^{2+}; (*e*) initially $2\cdot4 \times 10^{-3}$ (△) and $1\cdot2 \times 10^{-3}$ *M* Fe^{3+} (⊙)

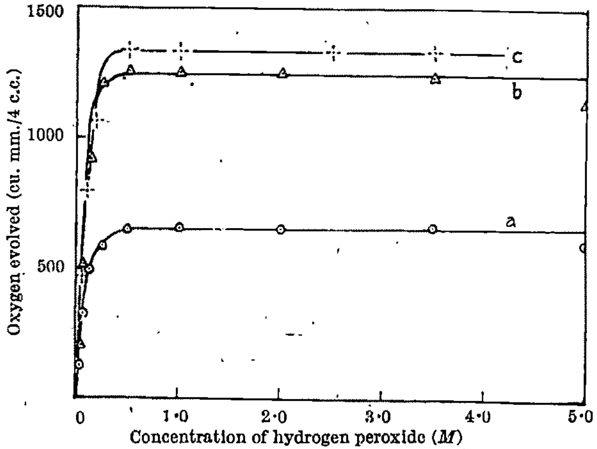

Fig. 2. Oxygen evolution from the reaction $Fe^{2+} + H_2O_2$ at various concentrations of hydrogen peroxide. (*a*) *p*H 1·5 ; (*b*) *p*H 1·8 ; (*c*) *p*H 1·5 with 4×10^{-2} *M* Fe^{3+} initially. Initial Fe^{2+}, 4×10^{-3} *M* in each case

initial concentration of ferrous ion, these deviations from second order increase with hydrogen peroxide concentration until eventually the effect of increasing the peroxide reaches a limit. This is paralleled by the dependence on the peroxide concentration of the total amount of oxygen evolved as the ferrous ions are oxidized to ferric ions given in (2) below.

Moreover, the course of a reaction from any time *t* onwards can be reproduced *ab initio* only with solutions of the same concentrations of hydrogen peroxide, ferrous ions and *also* ferric ions as at time *t*, but *not* with solutions containing the same concentrations of peroxide and ferrous ions alone.

(2) *Oxygen Evolution.* The total amount of oxygen evolved as the ferrous ion is oxidized to the ferric is easily determined from an oxygen evolution – time plot by extrapolating the linear portion, due to the subsequent catalysis of ferric ions back to zero time[4]. Above a certain H_2O_2/Fe^{2+} ratio it is found to be independent of the concentration of hydrogen peroxide and varies approximately inversely with the concentration of hydrogen ions over the range *p*H 1–2 (Fig. 2 (*a*) and (*b*)).

(3) *Effect of Ferric or Cupric Ions.* If ferric ions are added to a reaction mixture, the total oxygen evolved as ferrous ions are oxidized is greatly increased, and $k_{obs.}$ is less than 2 k_0 even at the beginning of a reaction. The same effect is observed with cupric ions, with the striking difference that the cupric ion is more efficient than the ferric (see Figs. 1 (*c*) and (*d*) and 2 (*c*)). This effect at first increases with increase of ferric or cupric ion ; but we find that for any given concentration of hydrogen peroxide and ferrous ion, the evolution of oxygen and deviations from second-order reaction are unaffected by further additions of ferric or cupric ions beyond a certain amount (see Fig. 1 (*e*)). In addition, at H_2O_2/Fe^{2+} ratios where the evolution of oxygen is normally independent of the concentration of hydrogen peroxide, it increases with the latter when these limiting amounts of ferric or cupric ions are present. Similarly, the limiting deviations from second order at high concentrations of hydrogen peroxide described in (1) above are no longer observed at sufficiently high concentrations of ferric and cupric ions.

(4) *Effect of Fluoride Ions.* In the presence of fluoride ions, the total evolution of oxygen is decreased, and a system which would have shown deviations from second-order kinetics no longer does so.

From the observations described in (1)–(4), we conclude that : (*a*) The oxygen is *not* evolved as the result of a reaction between HO_2 and hydrogen peroxide, with a terminating reaction between ferrous ions and $HO\cdot$ or HO_2. In these cases, it would always increase with the concentration of hydrogen peroxide, whereas we find it reaches a limiting value.

(*b*) The oxygen is evolved in a reaction involving ferric (or cupric) ions. This is probable because of the increase obtained by addition of these ions, and the decrease when ferric ions are removed by fluoride.

(*c*) Ferrous ions are regenerated by the oxygen evolution reaction. This is probable because we have found that at high H_2O_2/Fe^{2+} ratios, $k_{obs.}$ can be much less than k_0, the value it would have if all reactions involving ferrous ions, other than the primary step (*o*) above, were eliminated (see ref. 3). Hence ferrous ions must be regenerated during the reaction. Further, $k_{obs.}$ is even smaller, and thus ferrous ions are regenerated more rapidly when ferric (or cupric) ions are present initially, that is, under the conditions for increased oxygen evolution. The most probable reaction to account for these observations is one between Fe^{3+} or Cu^{2+} and HO_2.

(*d*) Another reaction which removes ferrous ions occurs in addition to reaction (1) above. This is required because the qualitative experiments with substrates suggest that most $HO\cdot$ reacts with hydrogen peroxide at high H_2O_2/Fe^{2+} ratios, and hence $Fe^{2+} + HO\cdot$ is no longer a significant reaction. But in spite of this, the ferrous ions are still removed initially at a rate which corresponds to that at low H_2O_2/Fe^{2+} ratios, that is, $k_{obs.}$ is always initially equal to 2 k_0 in the absence of added ferric ions. The kinetics can be accounted for if the additional reaction is between ferrous ions and HO_2.

Reaction Scheme. From these considerations we propose the following reaction scheme :

$$\begin{array}{llll}
Fe^{2+} + H_2O_2 & \rightarrow Fe^{3+} + OH^- + HO\cdot & k_0 & (o) \\
Fe^{2+} + HO\cdot & \rightarrow Fe^{3+} + OH^- & k_1 & (1) \\
H_2O_2 + HO\cdot & \rightarrow H_2O + HO_2 & k_2 & (2) \\
Fe^{2+} + HO_2 & \rightarrow Fe^{3+} + HO_2^- & k_3 & (3) \\
Fe^{3+} + HO_2 & \rightarrow Fe^{2+} + O_2 + H^+ & k_4 & (4)
\end{array}$$

At very low H_2O_2/Fe^{2+} ratios, only steps (*o*) and (1) occur, the reaction is second order and the evolution of oxygen is zero. As the ratio increases, the course of reaction is determined by competition for $HO\cdot$ in (1) and (2); hence the evolution of oxygen and deviations from second-order kinetics increase with the concentration of hydrogen peroxide. At high H_2O_2/Fe^{2+} ratios, the competition for HO_2 in (3) and (4) predominates, and since these do not involve hydrogen peroxide, the oxygen evolved and the kinetic deviations become independent of the concentration of hydrogen peroxide. The effect produced by cupric ions can be explained if they react more readily than ferric ions in (4), and we have

$$\begin{array}{ll}
Cu^{2+} + HO_2 \rightarrow Cu^{+} + O_2 + H^+ & (5) \\
Cu^{+} + Fe^{3+} \rightarrow Cu^{2+} + Fe^{2+} & \text{(very fast).}
\end{array}$$

These two reactions amount to a catalysis of reaction (4). The limiting conditions attained in the presence of ferric or cupric ions are seen to arise when (4) or (5) predominate to such an extent that HO_2 termination in (3) is no longer significant compared with $HO\cdot$ termination in (1). Under these conditions, the total oxygen evolved and $k_{obs.}$ should again be dependent on the concentration of hydrogen peroxide as observed.

The kinetics of the reaction and the amount of oxygen evolved are found to agree with the expressions which can be deduced from the above mechanism, and, from the kinetic analysis, values for k_4/k_3 and k_1/k_2 can be obtained. These will be discussed in a later publication. We find that k_1/k_2 is independent of pH, whereas $k_4/k_3 = \frac{K}{[H^+] + K_1}$ over the range examined. K_1 is found to be about 6×10^{-3}, which corresponds closely to the equilibrium constant of[5]

$$Fe^{3+} + H_2O \rightleftharpoons FeOH^{2+} + H^+.$$

The variation of k_4/k_3 with the concentration of hydrogen ions can be accounted for if the reactants in (3) and (4) are

(i) $Fe^{2+} + HO_2$, and $Fe^{3+} + O_2^-$
or (ii) $Fe^{2+} + HO_2$, and $FeOH^{2+} + HO_2$
or (iii) $Fe^{2+} + O_2^-$, and $FeOH^{2+} + O_2^-$.

A detailed kinetic analysis shows that only the reactions in (i) occur.

Ferric Ion Reaction

The catalytic decomposition of hydrogen peroxide by ferric salts has been found to be first-order both with regard to hydrogen peroxide and ferric ions, and to vary inversely as the concentration of hydrogen ions[1]. This kinetic form can be obtained if the initial reaction is

$$Fe^{3+} + HO_2^- \rightarrow Fe^{2+} + HO_2 \ldots . ki, \qquad (i)$$

and is followed by reactions (*o*), (2), (3) and (4) in the ferrous ion scheme above. The exclusion of (1) is justified since these experiments have usually been done at high H_2O_2/Fe^{3+} ratios. This mechanism is to be preferred to that proposed by Weiss[2] because it retains reactions which are necessary to explain the ferrous ion reaction, and which cannot be ignored in the ferric ion reaction. An important feature of the above scheme is that it is a chain reaction rather than a sequence of radical reactions as proposed by Weiss. Preliminary calculations using the constants derived from the study of the ferrous ion reaction indicate a chain-length of about 10^3.

A recent investigation of the ferric ion reaction by Andersen[6] shows that at *low* H_2O_2/Fe^{3+} ratios the reaction is no longer first order with regard to hydrogen peroxide, but somewhat higher. The data of Simon *et al.* show similar features[7]. The higher order can be understood if at these low H_2O_2/Fe^{3+} ratios reaction (1) becomes significant, for if (1) *completely* replaces (3), as a chain termination reaction, the decomposition-rate is given by

$$-d[H_2O_2]/dt = k\,[Fe^{3+}]^{1/2}\,[H_2O_2]^{3/2}. \qquad (6)$$

The well-established promotion by cupric ions of the ferric ion catalysed decomposition of hydrogen peroxide, which has been examined in some detail by Bohnson and Robertson[8], gives further support. They observed a limiting promotion effect by cupric ions which is similar to that described above in the ferrous ion reaction and can be explained in the same way, namely, by the predominance of reaction (5) over (3), causing all chain termination to occur by reaction (1), thus making the overall reaction independent of the concentration of cupric ions. Furthermore, the predicted rate expression in these conditions is the same as (6) above, and this is supported by the data available in that they show a dependence of the rate on the square root of the concentration of ferric ions, $[Fe^{3+}]^{1/2}$.

These ferric ion reactions are being investigated in more detail to check the above kinetic expressions.

We are indebted to Prof. M. G. Evans for advice and helpful discussions during the course of this work.

THE RARE ISOTOPE OF HELIUM, He^3; A KEY TO THE STRANGE PROPERTIES OF ORDINARY LIQUID HELIUM, He^4

By Prof. F. LONDON
Duke University, Durham, N.C.

A very interesting experiment with the rare helium isotope helium-3 has recently been made by D. W. Osborne, B. Weinstock and B. M. Abraham, of the Argonne National Laboratory in Chicago[1]. This experiment is crucial, as it may decide the correctness of a theory devised eleven years ago[2] to explain the peculiar properties of the fluid into which ordinary liquid helium turns when cooled below the temperature of 2·19° abs. (about two degrees below its normal boiling point of 4·2° abs.).

Above 2·19° abs., liquid helium behaves very much like any other liquid; it shows ordinary viscous flow, normal heat conductivity, etc. At 2·19° abs. it undergoes a strange change of state; its entropy, that is, its degree of thermal disorder, very rapidly decreases within a small temperature-range with a discontinuity of the specific heat at 2·19° abs. (λ-point). However, instead of solidifying as any other liquid would do if cooled to a sufficiently low temperature, liquid helium turns, below 2·19° abs., into a very peculiar kind of fluid, which has characteristically been called 'superfluid'. It no longer has an ordinary viscosity, it leaks through the finest cracks which were practically tight for helium, liquid or gaseous, above 2·19°. It shows a particular transfer of heat with a facility incomparably better than any other substance. One speaks of 'heat-superconductivity'. In addition, there are many other utterly strange features by which liquid helium below 2·19° abs., called 'liquid helium II', is distinguished from all other known liquids.

The theory proposed by me in 1938 tried to relate the unique properties of liquid helium II to those of what one calls an 'ideal Bose–Einstein gas'. In 1924, Einstein[3], generalizing ideas of the Indian physicist Bose, had developed a very strange concept of a gas consisting of identical molecules, which are assumed to be in a very radical sense indistinguishable from each other. He conceived that it should not only be impossible to distinguish a case (I) where molecule A is here and molecule B is there from another case (II) where molecule B is here and molecule A is there, but that one should not even count these two indistinguishable cases, I and II, as two separate cases; rather they should be considered as *one single case* only. Einstein remarked that this kind of taking away the last vestige of individuality from the molecules of a species would lead to a curious "condensation phenomenon". Even disregarding the forces between the molecules, one would obtain a peculiar change of state of aggregation at a well-defined temperature; the molecules would 'condense' in a certain, though not in a crystallized, state. Einstein himself did not give a detailed proof, and his strange remark received little attention at that time. Most people considered it as a kind of oddity which had, at best, an academic interest, since at the extremely low temperature in question there are no gases, all substances eing frozen or at least condensed. In addition, oubt was cast on the mathematical correctness of instein's remark. Thus the matter was dealt with a sense as if there is no 'Bose–Einstein conden- ation'.

When the strange properties of superfluid helium ecame known, during 1937–38, I remembered the marks of Einstein on the 'Bose–Einstein con- ensation', and worked out the theory in more tail. In the meantime, from quite another source, mely, from spectroscopic observations with helium lecules, direct evidence has been found which uld only be interpreted by assuming that per- itations of helium atoms are, indeed, to be counted the way suggested by Einstein. Thus it happened at only at that time it was ascertained that an al Bose–Einstein gas would actually show a break the specific heat, c_p. In particular, for molecules of e molecular weight and the density of liquid helium, is break would occur at a temperature of 3·09° abs., ry close indeed to the 2·19° abs. of the transition mperature of liquid helium. Allowance should, of ourse, be made for the fact that the intermolecular rces have been entirely neglected in this calcula- on. Thus I concluded that the strange change state in liquid helium, even though manifested in e fluid and not in the gaseous state, might be due the same mechanism the skeleton of which is ready visible if one simplifies the liquid to the gree that one disregards the forces between the olecules entirely. In some way this peculiar ndensation can be described by saying that it presents a kind of ordering process, though not so ch with respect to the location of the atoms in ce (as happens to be the case for an ordinary ndensation or crystallization), but rather with pect to their velocities.

t proved too difficult, however, to substantiate s idea directly by including the effect of the eraction forces in the calculations. Nevertheless, nerous qualitative consequences could be deduced m this interpretation without entering into the ails of such difficult calculations; these conse- ences corroborated a general concept which is now own as the 'two-fluid model' of helium II and which to a series of predictions of phenomena with uid helium which were not known at that time which were afterwards verified by experiments. obably the farthest reaching implications were dis- ered by L. Tisza[4]. We met when I was developing the above ideas about the Bose–Einstein condensation and its possible relation to the transformation of liquid helium into superfluid helium. Almost immediately he saw that this picture would imply, among other consequences, a very peculiar heat transport in superfluid helium, entirely different from the cumbersome mechanism by which heat is ordinarily propagated in matter (namely, by heat conduction or convection). It was inferred that heat could go through superfluid helium by way of a new kind of waves very much as sound does, with, however, a different characteristic propagation velocity. The velocity of these peculiar waves would depend on the temperature: it would be zero at 2·19°, would increase to a maximum at about 1·6° abs., and then again decrease for still lower temperatures.

When Tisza made this prediction (1938), practically no one took the theory seriously. It appeared too queer that the mere non-individuality of molecules should have such a very concrete measurable consequence. Thus nobody cared to make an experiment at that time in order to see whether there was any truth in this idea. The War came, most physicists were busy with war physics, and the whole theory was almost forgotten, when in 1941, in Moscow, a similar theory was developed by L. Landau[5], not quite independently of the foregoing development. Yet he contested the idea that the Bose–Einstein statistics had anything to do with the subject—arguing that liquid helium is not a gas, which fact, of course, has never been questioned. Landau's theory was supposed to be based on a quantization of hydrodynamics, but actually it seemed much more to rest on newer measurements with liquid helium, which were made in Moscow by Kapitza at the same time[6]. Some of Kapitza's results had been implied in the predictions Tisza had made three years earlier on the basis of the Bose–Einstein theory. Hence they ought to be considered as confirmations of that theory.

Unfortunately, it was difficult to appreciate Landau's theory, as its theoretical basis appeared quite obscure. On the other hand, it has not been possible so far to develop a rigorous statistical theory of the liquid state which includes both the Bose–Einstein condensation and the interaction forces as well. Yet so far as the measurable phenomena are concerned, the mathematical scheme yielded by either of the two theories, London–Tisza's on one hand, and Landau's on the other, seemed essentially the same. In particular, the new kind of wave propagation appears in Landau's theory also; Landau called the new waves "second sound", not quite appropriately, since it is heat rather than pressure which is being propagated.

But Landau, being close to an excellent low-temperature laboratory, now gave the incentive for further experiments. They were conducted by Peshkov in Moscow near the end of the War[7]. These experiments brilliantly confirmed the existence of the predicted 'second sound', or rather thermal waves, in all details. In particular, they confirmed the values predicted by the theory for the propagation velocity of these peculiar waves for all temperatures measured.

This showed that the equations which described the behaviour of liquid helium II in bulk were essentially correct. Yet it appeared to be an open question whether the original starting point of these ideas, the molecular mechanism of the Bose–Einstein condensation, was essential for the theory.

Quite recently a new possibility has opened for deciding, by experiment, the relevancy of the Bose–Einstein way of counting, without entering into the obscurities of complicated and approximate calculations. Ordinary helium (He^4) has an extremely rare isotope, He^3, which occurs in atmospheric helium, itself a very rare gas, only in a ratio of 1 : 1,200,000. There are very definite reasons, which cannot be explained here, which force the physicist to apply a different way of counting to helium-3 from that used for ordinary helium. According to this particular way of counting, called 'Fermi–Dirac statistics', the helium-3 atoms, at least if they are considered as force-free, would show *no condensation* of the kind derived for 'Bose–Einstein particles'. The manner in which one counts the permutations of 'Fermi–Dirac-particles' does not imply individuality of the molecules either; however, it has a peculiar feature in addition, in that it does not permit several particles of the same kind to have exactly the same velocity. This particular feature of the 'Fermi–Dirac particles' precludes a condensation mechanism of the type encountered for 'Bose–Einstein particles'.

The extreme rarity of helium-3 had prevented experiments with this isotope until recently. Now, appreciable quantities of this isotope can be obtained from the Atomic Energy Commission, since it is one of the many products which can be made by using the strong neutron beams of an atomic pile.

It has recently been possible to liquefy a fraction of a cubic centimetre of pure helium-3 and to measure its vapour pressure curve[8]. The critical temperature and the critical pressure are about 3·34° abs. and 875 mm. mercury respectively.

The experiment in Chicago referred to in the beginning of the present article attacks directly the question of whether or not liquid helium-3 at some temperature in the neighbourhood of 2° abs. becomes superfluid like helium-4. The liquid helium is being pressed through a fine capillary, and one measures the flow velocity at different temperatures. While for liquid helium-4 this flow velocity has, at 2·19° abs., a discontinuity and for lower temperatures suddenly becomes extremely large, the experiments with helium-3 show *no* remarkable change of the flow properties from 3° abs. down to 1·05° abs. The viscosity is of the same order of magnitude as that of liquid helium-4 above 2·19°, and considered as a function of temperature it shows *no discontinuity* in the whole temperature-range measured. This is a negative result, true, still a quite decisive one, since it settles a *qualitative* question. One might hold definite judgment in suspense until the experiment is extended to a still lower temperature. However, the temperature of 1·05° abs. reached so far ought to be quite sufficient to ascertain that the Bose–Einstein condensation mechanism represents the key to the understanding of the unique fluid state represented by helium-4 at temperatures below 2·19°.

WEATHER AND FARMING IN INDIA

THE world pattern of agriculture is largely determined by the world pattern of climate, and where wide fluctuations from average weather may occur without warning, the results may be catastrophic. Indian fear of flood and drought and of other weather extremes made it imperative that there should be some organised study of weather in relation to crops, and a recently published report* surveys the activities of the Agricultural Meteorology Branch of the India Meteorological Department set up for this purpose in 1932.

The survey is in two sections: the first gives the history of the formation of the Branch, a statement of its objects and a general review of work done up to 1946; the second gives a more detailed accoun of recent activity. One might reasonably expect to find some indication of the impact of the first sixtee years of work on Indian farming; but the mai emphasis is on what was planned, much less o results obtained, and there is none on the applicatio of the results. The report is completed by eleve appendixes, mainly reprints of scientific papers pu lished during the period 1946–48. In the first of the appendixes is a description of the Indian Cro Weather Scheme, and the report notes with natur pride that this scheme was adopted for world use b the International Commission of Agricultural Mete ology at Toronto in 1947. Aiming at the collect of relevant crop and weather data throughout growing year at a network of stations, the sche differs, only in non-essential details from the Brit Crop Weather Scheme started in 1922. As this h been as near a failure as human pride will ever adm it seems a pity that an international conferen should agree to a world-wide experiment witho first being sure that it can be successfully carr out in at least one place. The British Scheme bro down on the biological side, and in this Indian repo there are several hints of difficulties being met in t estimation of "the state of the crop".

An interesting aspect of the work of the Agricultur Meteorological Branch is its attempt to establish weather service for farmers; when the service h been in operation for some years, a critical account its running (including failures as well as success will be of immense value to agricultural meteorolog Seven regional forecast centres have been set up issue detailed weather bulletins and warnings farmers, and the centres are being supplied wi "Crop Weather Calendars" showing the life-hist of the chief crops of the region, their normal weat requirements, and the abnormal weather for wh warnings are necessary at different periods dur growth. This experiment might well be tried e where, and even in Great Britain the regional divis should be regarded as an essential part of the schem

The remainder of the report is largely concern with the work of the observatory at Poona, set in 1933. Again the account is mainly of activ without any attempt at a synoptic survey; there is an impressive list of research problems be investigated in the main branches of agricult meteorology, with an understandable emphasis the physical problems of the heat balance and t water balance of the soil, turbulent diffusion and t n of new instruments. The 1946–48 section more detail than one normally expects in a or's report; but this detail includes some cting tables of night radiation to cloudy and skies, tables of root development and crop h as a function of depth of water-table, and rative readings for different types of evapori- It is to be regretted, however, that physicists waste their time on the Piche and Wild ents.

ARNEGIE TRUST FOR THE NIVERSITIES OF SCOTLAND

HE forty-seventh annual report of the Carnegie Trust for the Universities of Scotland for the 1947–48 refers to the loss sustained by the death e chairman of the Trust, Sir Robert B. Greig, on mber 29, 1947. He has been succeeded by Sir Ireland Falconer.

the field of research, demands for assistance travel and maintenance grants increased, and executive granted £4,000 to supplement university s for assisting professorial and non-professorial in this way. Special grants were made to St. rews for the purchase of four Bell-Gaumont ectors with accessories; to Glasgow for electro- esis apparatus for the Department of Bio- istry; to Aberdeen for maintenance of the mming pool at King's College to permit free use; to Edinburgh for provision of equipment for istic and folk-lore recording in both Gaelic and tish areas. Assistance given to students decreased 7,992 to £43,040, the number of beneficiaries de- sing from 3,068 to 2,368; repayments by former ficiaries also decreased to £2,634, from fifty-four ficiaries.

tails of the eighth quinquennial distribution 7–52) are given in an appendix. They include 350 to the St. Andrews Centre, of which £12,000 housing for university staff, £5,500 for scientific pment, mainly for research, and £6,600 for equip- for the Advanced Medical School and £13,350 niversity College, Dundee, of which £2,350 also is for scientific equipment, mainly for research. Grants to the Glasgow Centre include £70,000 to the University towards erection of the final portion of the Chemistry Institute, £5,500 to the Royal Technical College for the development of a College library service, £2,500 to the West of Scotland Agricultural College and £3,000 to the Scottish Marine Biological Association for renovating the aquarium at Millport Station. Grants to the Aberdeen Centre include £5,000 to the University for library books, £42,000 towards the cost of a new Chemistry Department, £4,000 for equipment for the Mechanical Engineering Department of Robert Gordon's Technical College, £1,000 each to the North of Scotland College of Agriculture and the Macaulay Institute for Soil Research, and £2,000 to the Rowett Research Institute. Grants to the Edinburgh Centre include £23,000 to the University for library expenditure, £20,000 for a lectureship in phonetics and £25,000 for capital expenditure on the Bush and Dryden estates, £5,000 to the Heriot-Watt College for special equipment in the Mechanical Engineering Department, and £2,000 each to the School of Medicine of the Royal Colleges, the Royal (Dick) Veterinary College and the Edinburgh Dental Hospital and School.

The new scheme for the award of fellowships, scholarships and grants for research is again appended, with details of awards made for the year 1948–49, and a list of publications from beneficiaries during 1947–48. In a note on the work of investigators under the research scheme during the year, reference is made to that of Dr. T. S. Hutchison on the strain sensitivity of magnetic susceptibility, of Mr. F. B. Stern on the crystal structure of tartaric acid, of Mr. E. Reid on the diabetonic principle of the anterior pituitary body, and of Miss D. C. Gibb's progress in her investigations on free-growing fucoid algæ. Dr. C. C. Forsyth has continued an intensive study into the place of free diet in the treatment of diabetus mellitus, Mr. J. B. Wilson his investigations of the rates of absorption of different amino-acids of different molecular weight from the intestine of the rat and cat, and Miss R. M. Campbell her study of the effects of various factors on the structure of the liver.

Work in chemistry has chiefly been a consolidation of earlier studies, but special mention is made of Mr. G. W. Youngson's work on polymerization, in which he has built up, on the basis of the pentaerythritol molecule, remarkable 'cruciform' macromolecules in which four big chains of approximately equal length, built up of alternate glycol and adipic acid residues, radiate from a single carbon atom, and more recently, on the dipentaerythritol and trimethylolpropane molecules as bases, six-rayed star-shaped and 'double-Y-shaped' molecules. Mr. C. T. Dickson has continued to work on the structure of colchicine, and Mrs. Storey and Miss B. Cairns on the synthesis of benzacarboline and methoxybenzcarboline and of benzacridone analogues of mepacrine as of possible interest as anti-malarials.

Dr. A. Lamont's work on the rocks in the Pentland Hills assigned to the Silurian system has led to a tentative opinion that the rocks are of earlier date than has generally been accepted. Dr. F. H. Stewart has proved the presence in the complex of basic rocks at Belhelvie, near Aberdeen, of a type of banding, attributed to gravitational settling, that seems to be paralleled in other parts of the world. The Trust has given important aid in the publication of

Dr. A. E. Trueman and Dr. J. Weir's extensive work on British Carboniferous Non-marine Lamellibranchiata. Mrs. E. M. Knox has continued her work on the spores in coal, Miss D. Elrich, at the University of Budapest, has investigated industrial conditions in Hungary, Mr. Gilfillan the social and economic development of Dumbartonshire in the nineteenth century, and Miss A. M. Keay a study of the Forfeited Estates Papers in H.M. Register House, Edinburgh, with the view of elucidating the effect of the policy of the Commissioners on the social and political organisation of the Highlands during the eighteenth century.

The report of the superintendent of the Laboratory of the Royal College of Physicians, Edinburgh, pays a tribute to the work of Lieut.-Colonel W. F. Harvey, who was in charge of the Histopathology Department for twenty years and whose death on September 11, 1948, was a great loss to the Laboratory. Research on the chemotherapy of cancer using transplantable tumours in mice continued, while in biochemistry the discovery of new chemotherapeutic agents was again a chief objective. Some p-phenanthroline compounds proved to have considerable action against avian malaria, and the preparation of chloro derivatives has been completed. Work has also continued on the synthesis of p-phenanthroline compounds containing two basic side-chains, and a number of benzthiazole derivatives, chiefly 6-nitro- and 6-amino-2-styryl derivatives, have been prepared for test for antifilarial activity. The synthesis of benzthiazole compounds has been the chief concern of Dr. J. E. McKail.

CHEMOTHERAPY OF TUBERCULOSIS

THE fourth meeting of the Fine Chemicals Group of the Society of Chemical Industry was held at King's College, London, on January 18, with Sir Jack Drummond in the chair. A discussion on "The Approach to the Chemotherapy of Tuberculosis" was opened by papers by Dr. James Walker and Dr. P. M. D'Arcy Hart, both of the National Institute for Medical Research.

Dr. James Walker said that the limited knowledge of the metabolic processes of the tubercle bacillus has made an empirical approach to chemotherapy inevitable; but research has been aided by the use of wetting agents, such as 'Tween 80', and the addition of serum albumin to liquid media, which make it possible to obtain visible growths from minute inocula of the organism. Compounds at present under trial include the sulphones, which probably exert their action in the body by slow hydrolysis to diamino-diphenylsulphone; the diphenylamine o-carboxylic acids which act as antioxidants in certain biological oxidation mechanisms, and which have shown some inhibitory activity *in vitro*; and the di-alkylsuccinic acids and other substances with lipophilic terminal groups, which may aid penetration of the drugs into the lipoid-rich bacillus. Various antibiotics have been tried against the tubercle bacillus, the best so far being streptomycin.

Dr. D'Arcy Hart said that sulphetrone and its analogue promizole, the least toxic of the sulphones, have produced some regression in the acute forms of human infection, and calciferol has brought about dramatic and consistent improvements in lupus vulgaris. Streptomycin has proved life-savin proportion of cases of tuberculous meningit miliary tuberculosis, hitherto invariably fatal, is useful in less serious forms of the disea clinical use is limited by its toxicity and by th resistance which develops in some patients treatment. Lastly, p-aminosalicylic acid h promise and is under trial in Great Brita alone and in conjunction with streptomycin

Much yet remains to be done; but chemothe already given a new edge to the sword of e practice, and the time may not be far tuberculosis will cease to be the greatest d useful lives in Western civilization.

CORRELATION OF EVOLUT OF HOST AND ECTOPARAS

UNDER the title "Some Rules in Ectoparas Dr. W. Eichler, of Ascherleben, German tributes an interesting paper to *The Anna Magazine of Natural History*, Series 12, No. 8 (1948). It has long been known that the classification of some groups of animals of habits corresponds with that of their hosts Fahrenholz was one of the chief protagonists rule (in regard to the Anoplura in particula author has named this general principle "F holz's Rule". It applies, for example, to groups of ectoparasites and their hosts. Fahr argued that the ancestors of extant parasites have been parasites of their original ancestral evolution of host and parasite consequently gone on side by side. The conclusions drawn the classification and relationships of many gro parasites enable light to be thrown on the n relationships of their hosts—even in cases whe latter show very divergent features from members of their group.

One of the best examples of the working principle is in the case of the flamingo—a bird is placed by some ornithologists among the whereas others relegate it to the storks. Thos think it to be a duck explain its long stork-li as convergence owing to similarity of habit. maintain that it is, in fact, merely an aberrant whose duck-like bill is the result of convergence evidence afforded by the parasites of flam strongly argues in favour of their derivation those of ducks. Thus the bird lice show in the a clear affinity with those living on the An The ostrich and rheas are only parasitized b lice and feather mites common to those birds. evidence is also confirmed by the cestode nematode parasites of those two groups of bird

Szidat (1939) has shown in his studies of th cycles of Trematoda that primitive hosts are sitized by primitive types of tremades and speci hosts by specialized parasites. He quotes the par of various vertebrates in support of his conte In the trematode subfamily Asymphylordorina hosts are fishes of the family Cyprinidæ, which their developmental centre in East Asia. In region some of these Trematoda occur among dif genera of Cyprinidæ, but with the spread o fishes to Europe the parasites become more spe a with the result that they become restricted particular Cyprinid genus or, in one case, to a species.

Eichler also explains what he calls the gence rule". Where there are groups of hosts many species, he deduces the rule that the more host is infested by different genera of parasites er must be the group to which that host This principle is illustrated by many of the aga that infest large groups of closely related The fact that the tinamon Mallophaga are nerous in genera is exceptional for the para- bird group containing so few species. It perhaps, that the Tinamidæ was a much oup of birds at one time, most of its species lied out.

ESEARCH IN INDUSTRIAL RELATIONS

the 1948 mid-winter meeting of the American Philosophical Society, which was held at Phila- ia in February 1948, papers were read dealing research frontiers in human relations.

of these papers, by Prof. E. Wight Bakke, of niversity, dealt with the subject of research ndustrial relations and suggested that the in recent years by leaders of management and r for basic principles of human relations on they might build new techniques in their own or- ations has been in vain (*Proc. Amer. Phil. Soc.*, 92, ; Nov. 12, 1948). According to Prof. Bakke the ologists have come closest to providing the cal men with the most useful principles, and of them have contributed by the development of for prospective employees, attitude surveys, niques for building morale, training of supervisors, similar projects. Other psychologists have also rtaken a careful analysis of the motives for and minants of behaviour among workers themselves. ropologists, sociologists and economists, too, carried out investigations; but these have only loosely connected with the subject of trial relations, and no common theory running gh this research into human relations has ged.

is not surprising, therefore, that the leaders of gement and labour have been unable to turn to a ndable and useful science of human relations. ner is it surprising that the men of action have been able to find what the men of science have unable to find or produce, namely, an integrated of principles of human behaviour on which the niques for the organisation and direction of an beings in purposeful group activity' could ested and on the basis of which effective action d be developed.

an attempt to determine the particular type of arch into industrial relations in which the elopment of a scientific theory of human inter- ion and of the determinants of human behaviour ld be the dominating consideration, Prof. Bakke ts that industrial relations are simply one kind of an relations. The principles which govern men's ns and relations in industry are no different lly from those which govern their social, their s, their familial, their educational, and their ical activity and relations. The distinguishing ks of this kind of industrial relations research ld be :

1) The general problem must be defined as one earning the determinants of human action.

(2) Specific questions must be shaped by reference to the need for amplifying or modifying a basic theory of cause and effect.

(3) Group-wide or group-wise behaviour and the group as an organic entity must be emphasized.

(4) A diagnostic pattern outlining all personal and environmental facts needed for adequate explanations must be utilized.

(5) Attention must be paid to the definition and measurement of data in quantitative terms.

(6) Field observations must be used as the major source of data.

(7) Theory must be progressively formulated and tested in the laboratories of industrial and union operations.

This kind of research may be described as a 'frontier' activity primarily because it is seeking to develop systematic principles of cause and effect in a field of behaviour in which such principles are not understood. Here the most pressing need of to-day is for studies not only of personnel policies but also the nature of persons; not only of incentive systems but also of human incentives; not only of collective bargaining procedures but also of the factors which mould the actions and attitudes of the bargainers; not only of bargaining issues but also of the structures of living of the parties which give them varying and conflicting 'slants' on the issues; not only of the structure of management and unions, but also of the compulsions these structures impose upon the actions and thoughts of the men who represent them; not only of techniques for organising enterprises or unions, but also of the principles of effective association and group solidarity and teamwork.

This type of research raises many problems, in addition to the scientific problems of the research itself. It is expensive. The facts must be gathered through field-work of a comprehensive nature. The personnel who can collect the facts must have a breadth of training and knowledge preferably in more than one discipline. A further difficulty arises out of the necessity for a partnership of the men of science with the men of action, management and trade unionists, in the collecting of facts and the testing of conclusions. Even when co-operation is obtained, there is the necessity for accurate and full reporting of results which are not always easy to reconcile with the requirement for avoiding harm, actual or feared, to the co-operating organisations and individuals. There is also the necessity for using a language in describing scientific results which is understandable to men who are not trained in science.

In conclusion, Prof. Bakke describes the value of theory in the advancement of knowledge and its application to the solution of the world's industrial problems. The increase in quantity and quality of material goods which flow from industrial operations is as dependent on the effective co-ordination of people and efficient team-work as upon the adequacy of tools and technique. The processes of democratic society are seriously disturbed by industrial warfare. The practical decisions in ordering human relations so that the public interest may be met depend on the leaders of industry and unions. Changes in technology, in economic, social and political situations, are constantly inserting elements, of which the old techniques took no account, into the problem. To-day, more than formerly, he is poorly equipped for adaptive action, in industry or elsewhere, who knows merely what to do but not why he does it.

T. H. HAWKINS

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 2

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5.30 p.m.—"As Seen by Denmark" (Sound films with introduction by Dr. Ingolf Boisen).

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Bernard Payne: "Air Lift Pumping".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. F. J. Cole, F.R.S.: "Aspects of Biological Discovery, 1, Spontaneous Generation".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Capt. H. Topley: "Navigation at Sea" (Science and Marine Navigation, 4).

Society of Chemical Industry, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Annual General Meeting; Mr. M. P. Balfe: "Leather—the Scientific Background to a Traditional Industry".

Tuesday, May 3

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Annual General Meeting; Dr. L. E. Rya[illegible]: "The Scientific Work of the Post Office".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. M. Grace Eggleton: "Physiological Properties of Ethyl Alcohol".* (Further Lectures on May 10 and May 17.)

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. G. W. O. Howe: "Some Electromagnetic Problems".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. J. McConnell: "Function Space and Applied Mathematics".* (Further Lectures on May 4 and May 6.)

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Scientific Approach to Human Problems in Industry" (to be opened by Sir Frederick Bartlett, F.R.S., Mr. Alec Rodger and Dr. Elliott Jacques).

Wednesday, May 4

Royal Society of Medicine, History of Medicine Section (at 1 Wimpole Street, London, W.1), at 4.30 p.m.—Annual General Meeting; Dr. E. Ashworth Underwood: "To Edward Jenner on his 200th Birthday" (Presidential Address).

Society of Public Analysts and other Analytical Chemists (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Scientific Papers.

Thursday, May 5

University of London (at Wye College, Ashford, Kent), at 5.15 p.m.—Prof. G. E. Blackman: "Modern Methods of Weed Control".*

Institution of Electrical Engineers, Utilization Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. F. E. Rowland: "Some Aspects of Agricultural and Horticultural Electrification in the United States".

Royal Meteorological Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 6 p.m.—Mr. E. Gold, F.R.S.: "Meteorology in the First World War".*

British Institution of Radio Engineers, North-Western Section (in the Reynolds Hall, College of Technology, Manchester), at 6.45 p.m.—Mr. W. G. Roberts: "Ceramic Capacitors".

Friday, May 6

Physical Society (at the Royal Institution, Albemarle Street, London, W.1), at 4.30 p.m.—Annual General Meeting; at 5 p.m.—Prof. G. I. Finch, F.R.S.: Presidential Address.

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. P. E. Kent: "A Structure Contour Map of the Pre-Permian Rocks of England and Wales".

Friday, May 6—Saturday, May 7

British Rheologists' Club (joint meeting with the Local Section of the Chemical Society, at the Washington Singer Laboratories, University College, Exeter), at 9.45 a.m.—Discussion on "Suspensions and Sedimentation".

Saturday, May 7

Biochemical Society (in the Department of Biochemistry, University Museum, Oxford), at 1 p.m.—Scientific Papers.

Linnean Society of London (at the Herbarium, Royal Botanic Gardens, Kew), at 2.30 p.m.—Demonstration: "Botanical Taxonomy after Linnaeus".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Science Officer, Directorate, Shanghai—The Director, Personnel Department, British Council, 3 Hanover Street, London, W.1 (May 7).

Senior Lecturer or Lecturer in Cytology, and a Senior Lecturer or Lecturer in Genetics—The Registrar, The University, Manchester 13 (May 7).

Mechanical and Aeronautical Engineers (unestablished Senior Scientific Officer grade) with experience in airframe stressing and design calculations or in the design and development of small mechanical components, at Royal Aircraft Establishment, Farnborough and other Ministry of Supply Establishments in South England—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting C.882/48A (May 7).

Senior Lecturer in Mechanical Engineering—The Principal Royal Aircraft Establishment Technical College, Farnborough, Hant. (May 7).

Lecturer in Philosophy—The Registrar, King's College, Newcastle-upon-Tyne (May 7).

Physical Chemists as Scientific Officers at a Ministry of Supply Research and Development Establishment near London, for duties in (*a*) high temperature refractories, (*b*) crystallography and practical microscopy, (*c*) spectrography, and (*d*) plant development—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1025/48A (May 10).

Wellcome Research Fellowship in veterinary science or practice—Dr. W. R. Wooldridge, Animal Health Trust, 232–235 Abbey House, Victoria Street, London, S.W.1 (May 14).

Lecturers (2) in Fuel Technology, an Assistant Lecturer in Physics, and an Assistant Lecturer in Geography—The Registrar, The University, Sheffield (May 14).

Lecturer or Assistant Lecturer in Genetics, a Lecturer in Botany (preferably with Morphology or Ecology as a special interest), an Assistant Lecturer in Plant Physiology, and an Assistant Lecturer in Geography—The Secretary of University Court, The University, Glasgow (May 14).

Leverhulme Studentships in Chemical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (May 15).

Fellowship and Scholarship for session 1949–1950—The Secretary, British Institute of Archæology at Ankara, 56 Queen Anne Street, London, W.1 (May 16).

Lecturer and an Assistant Lecturer in the Department of Zoology, a Lecturer in Industrial Hygiene and a Research Assistant in Social Medicine in the Department of Social and Industrial Medicine—The Registrar, The University, Sheffield (May 21).

Chief of Division of Electrotechnology, National Standards Laboratory, Sydney (Ref. No. 2208), a Senior Research Officer on the Editorial Staff of the Council for Scientific and Industrial Research, Melbourne (Ref. No. 2188), and a Research Officer, Division of Plant Industry, Hobart (Ref. No. 2068)—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (May 21).

Senior Lecturer in Psychology (General Psychology with special emphasis on Educational Psychology) in the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 30).

Senior Lecturer in the Department of Electrical Engineering in the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, May 31).

Assistant Lecturers or Lecturers in Pure Mathematics, Applied Mathematics, Civil Engineering, Mechanical Engineering, Agricultural Organization and Economics, and Agricultural Chemistry, at the Gordon Memorial College, Khartoum—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (June 1).

Lecturer in Physics (in Pietermaritzburg), a Lecturer in Experimental Physics (in Durban), and a Lecturer in Botany (in Pietermaritzburg), in the University of Natal—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (June 15).

Senior Research Officer-Chemist, and a Research Officer-Chemist, in the Paint Industries' Research Institute of the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (June 30).

Technician for the Physiology Department—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Lecturer in Dairying, and Assistant Lecturers in Agricultural Chemistry and Genetics, at the School of Agriculture, Sutton Bonington, Loughborough—The Registrar, The University, Nottingham.

Graduate (preferably with research experience in biochemistry or chemistry) to assist in investigations on intermediary metabolism—The House Governor and Secretary, Royal Cancer Hospital, Fulham Road, London, S.W.3.

Lecturer in Botany (with special reference to plant metabolism), Assistant Lecturers in Geography (with special qualifications in Political Geography) and Mathematics, and Demonstrators in Botany (*a*) with one year's experience of research in mycology, (*b*) with one year's experience of research in bacteriology—The Registrar, The University, Nottingham.

Cerealist by the Government of Iraq for the Directorate-General of Agriculture—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18187.3F.

Assistant Professor of Anatomy—The Dean of Medicine, University of Alberta, Edmonton, Alberta, Canada.

Laboratory Steward—Prof. I. Manton, Department of Botany, The University, Leeds 2.

Physical Chemist or Metallurgist for work in connexion with both laboratory and practical studies of various aspects of iron-making processes—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Iron Making'.

Lecturer in Chemistry—The Principal, Royal Technical College, Salford 5.

Director of the West African Building Research Organization—The Under-Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1.

Head of the Department of Flight—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks.

WESTERN CIVILIZATION AND FREEDOM OF THOUGHT

"THE scientific outlook and scientific power increasingly dominate our age," writes Mr. John Bowles in his recent book "The Unity of European History"; and, in words strongly reminiscent of those used by H. A. L. Fisher in "A History of Europe", Mr. Bowles continues: "but unless traditional humanist values can be adapted and preserved, the progress of science will be empty and catastrophic. The study of the European past demonstrates the unity of Western culture, the values of the Christian and the Humanist tradition and the pernicious limitations of nationalism and class war. In the light of such knowledge, science can build a society which combines the power of modern technique with the spiritual depth of old experience." Mr. Bowles's political and cultural survey is written largely around a sentence of Mr. Winston Churchill's speech at The Hague Congress of Europe on May 7, 1948, as text: "We shall only save ourselves from the perils which draw near by forgetting the hatreds of the past, by letting national rancours and revenges die, by progressively effacing frontiers and barriers which aggravate and congeal our divisions, and by rejoicing together in that glorious treasure of literature, of romance, of ethics, of thought, and of toleration belonging to all, which is the true inheritance of Europe". To the scientific element in that inheritance Mr. Bowles possibly does less than justice, particularly to its cultural and political significance. Nevertheless, his book displays the vitality as well as the success of European civilization, and he shows clearly how much we have to learn from past ages as to the real nature of the dangers that threaten us to-day.

Like the Russian historian, Restovtzeff, Mr. Bowles sees in the failure of the upper class in the Roman world to extend their culture to the rural and the urban proletariat the fundamental cause of the decline of ancient civilization; and he observes that civilization is dependent on an individual creative genius, on the maintenance of a favourable environment for its realization and upon the preservation of intellectual standards. "No more than Græco-Roman society can modern society continue stable unless the masses participate in the minority culture without lowering its quality. It is the cardinal task of modern civilisation to preserve such standards, to democratise culture without debasing it, to transmit a modernised version of traditional values to the masses and to create a public opinion which respects knowledge."

The recurring theme throughout the book is that freedom of thought and the Christian respect for the individual are the very roots of European civilization, and Mr. Bowles shows from what diverse sources the tradition is derived. He quotes Spinoza that "the ultimate aim of government is not to rule by fear . . . but to free men from fear . . . to enable men to develop their minds and bodies in security and to employ their reason unshackled"—words which are strangely pregnant again to-day; and on the other hand, he shows the evil that flowed from Hegel's attack on individual rights and impartial law. He brings out, too, the way in which the increase in population, the intricate world-wide structure of modern industry, the revolution in transport and so on have made imperative a planned international and economic order.

Even where Mr. Bowles simplifies too much, he rarely fails to show that the outstanding characteristics of Europe have been freedom and initiative, reflecting a fortunate environment, and that from this enterprise have flowed a brilliant and diverse culture and unprecedented scientific power, the immense advantage of which Western Europe has enjoyed over the rest of the world through its long lead in scientific and industrial techniques. He does not rest content with stressing the dependence of the democratic way of life for its continuance on a co-ordinated drive to ensure self-government and the rule of law in national and international affairs which will guarantee freedom from fear; with the planning of economic life to ensure freedom from want; with the maintenance of freedom of worship, thought and speech. He also points to definite responsibilities in this field on the part of professional organisations.

The vitality needed to deal with contemporary dangers, Mr. Bowles reminds us, can only be maintained by preserving the widest freedom of thought. Such freedom has been the secret of all the great creative epochs, as of modern science itself, and with it now must go the maintenance of independent professional organisations, strong enough to influence public opinion and the policy of the State, and uniting professionally competent experts in a common front. If this freedom and unity can exist, a creative civilization can continue: the alternative is totalitarianism.

Mr. Bowles thus regards professional organisations as possessing the same vital functions for civilization that were visualized by Sir A. M. Carr-Saunders and P. A. Wilson in their study of the professions published some sixteen years ago. They saw vocational associations, with the emphasis shifted from mere organisation to vocation or service, as providing professional men with permanent anchorage and shelter, from which secure positions they could set out to shape organisations into instruments for the fulfilment of their purposes. Carr-Saunders and Wilson had then sensed something of the oppression which the rising totalitarian systems were to exert, and of the need for democracy to brush away inefficiency and organise a free society for the good life. The years between have emphasized the continuing reality of that threat, and the dependence of progress upon a minority of creative minds functioning in an environment of freedom of thought and utterance.

To maintain intellectual standards and the intellectual freedom in which alone they can be preserved is a first responsibility of all professional associations. Some such bodies have always had special responsibilities in this matter, and have rarely for long been unmindful of them. Dr. A. Mansbridge noted, for example, in "The Kingdom of the Mind", that all the old universities of Europe represent historically the development of communities for common interest and protection in the pursuit of learning; and, abov all things, their story is the story of European unit and citizenship. Recognition that the universiti and professional institutions have a part to play i the defence not merely of freedom of expression bu even of freedom of thought itself, should not lead u to overlook their continuing contribution to Europea and indeed world unity. Moreover, the conditions i which alone science and scholarship can flourish, o even exist, are those where respect for truth an respect for persons are inherent in the general soci tradition.

The essential basis of unity for Western Europ is not a political creed but a belief in all the principle linked with an indispensable principle of liberty, an the defence of that liberty is not primarily a politica issue but a responsibility resting on all such institutions as universities and professional associations a well as religious bodies. Moreover, as Prof. R. B Goldschmidt recently emphasized, it is only in th last two decades that there has been any seriou interference with the freedom of science by Governments. There have always been organised groups o different types who clamoured for such interference but in the nineteenth century even the wors reactionaries did not go so far as to abolish th freedom of teaching. Incidentally, Prof. Goldschmid takes the same view as Sir Robert Robinson, in hi presidential address last year to the Royal Society that in Great Britain the immediate danger to th freedom of science is less of direct attack than o relative depreciation of fundamental research in comparison with technological applications. The body scientific can only flourish when all its organs are i a healthy condition, and where there is a socia tradition which respects truth, even abstract truth for its own sake.

The most important chapter in Prof. G. S. Ghurye' recent book, "Culture and Society"*, is that in which he deals with this question, and more generally with the part the universities have to play in creating an maintaining civilization and culture at a high level Just how high cultural values are to be created an maintained, or how the passive practitioners o culture are to turn civilization into culture, he does not indicate; but very clearly he regards it a primarily a task to which the universities mus contribute the inspiration. He recognizes that ther are potentialities in planning which tend to work against individual development and realization; an that a planning society, if it cares for civilization an culture, must strengthen its universities. He remind us that it is the business of social organisation t provide conditions wherein individuals can realiz themselves to the fullest; while the strengthening o the universities involves both full autonomy in th body politic and redressing the balance of studies, nov tilted heavily in favour of science and technology, s that the humanistic studies are adequately developed

Here Prof. Ghurye is positive and emphatic, an although his otherwise somewhat discursive surve of nineteenth- and twentieth-century thought gives no clear answer to the questions: "What is culture?", and "What is civilization?", he may well have helped his readers to find their own answers. His book should correct some shallow thinking. Like Mr. T. S. Eliot, he recognizes that the whole of European culture is largely the product of Christianity. Like Mr. Eliot, too, he urges the maintenance of standards and the return to the study of those subjects by which the essentials of culture are transmitted; but he shows something which Mr. Eliot does not, namely, the seed of faith in our humanity. Prof. Ghurye has not entirely lost that faith in the power of man to preserve the best of his old culture while creating from his own spirit a new culture. He demonstrates anew the relevance of much of the thought of Whitehead, Russell and others to this problem of the nurture of a free culture in which creative thought is possible, and the vital necessity of free institutions under a democratic regime. Though he touches only the fringe of the political field, the implication is plain: that the universities, professional associations and the learned societies must take thought and care that the life of the society in which they are placed is not so ordered as to preclude the essential conditions for their work.

---

* Culture and Society. By Prof. G. S. Ghurye. (University o Bombay Publications, Sociology Series No. 1.) Pp. x+237. (Bomba and London: Oxford University Press, 1947.) 30s. net.

An immense responsibility thus rests on the universities and the professional bodies, including the learned societies; but it carries no implication that scientific men and other scholars are inherently qualified to be the saviours of society. They must, indeed, meet the fresh threat, wherever it comes from, to their right to declare and sustain by argument what they believe to be true, a right which has long been the condition of the whole intellectual life of Western Europe. On the right to make and test hypotheses through observation and experiment, to proclaim freely and discuss the conclusions to which inquiry leads, there can be no compromise. When that way is imperilled, scientific workers are bound to join, with fellow men of learning and of every walk of life, to safeguard the continuance of those free institutions through which the great heritage of Western culture has flowed, or they repudiate the very spirit and method of science.

OSCILLATING STARS

The Pulsation Theory of Variable Stars

By Svein Rosseland. (International Series of Monographs on Physics.) Pp. viii+152. (Oxford: Clarendon Press; London: Oxford University Press, 1949.) 18*s*. net.

CEPHEID variable stars—the name given to stars which behave like δ Cephei—have played a distinguished part in modern astronomy. Their most characteristic feature—that there is a definite relation between period and median absolute luminosity—was discovered by Miss Leavitt in 1912 when investigating the Lesser Magellanic Cloud. Owing to this relation, the measurement of period and apparent magnitude allows one to compare the absolute and apparent luminosities, and so affords a reliable estimate of distance, once the zero point of the period-luminosity curve has been fixed. In this way, Shapley determined the distances of the globular clusters, and Hubble determined the distances of the extra-galactic nebulæ.

This would be sufficient glory for any ordinary type of star, but Cepheids have other claims to distinction. Originally supposed to be close binaries in virtue of the periodic shifts in their spectral lines, they were identified by Shapley in 1914 as stars in a state of pulsation, and it was Eddington's attempt in 1917 to give Shapley's hypothesis a precise mathematical form that led Eddington to investigate the equilibrium of non-pulsating stars as a norm, and so to put forward his celebrated theory of the radiative equilibrium of the stars. In another direction, the slow secular decrease in the periods of Cepheids led Eddington to an estimate of the rate of stellar evolution. Since then, their intriguing features have led a host of observers to make refined observations of their light-curves and velocity-curves, and a host of mathematicians to elaborate the pulsation hypothesis.

For several years now, Prof. S. Rosseland, of Oslo, and his co-workers have been engaged in studies of solar and stellar hydrodynamics, and the present admirable volume from his pen gives a detailed account of the application of hydrodynamics to the case of stellar pulsations. It contains not only the classical pioneer investigations of Eddington, but also the less well-known recent researches of the American and Dutch schools, together with many hitherto unpublished results of Rosseland himself. The whole book is written in a most attractive style. Rosseland uses his earlier experience in the analytical dynamics of the quantum theory to put the theory of radial pulsations of spheres of gas into canonical, Hamiltonian form, and exhibits it as a branch of the grand theory of oscillations of dynamical and thermodynamical systems. The issues are thus presented in a form which will appeal by its generality to a large class of readers over and above those professionally interested in variable stars.

Almost every theoretical astrophysicist has had a shot—many of them substantially more than a shot—at solving the outstanding problems which Cepheids offer on the pulsation hypothesis, such as the skewness of the velocity- and light-curves, and the coincidence of maximum luminosity with maximum velocity of approach of the stellar surface. The full bibliographical references given by Rosseland make the reader realize how great a loss the subject suffered through the early death of Woltjer, the Dutch astronomer; and what important contributions have been made recently by Martin Schwarzschild, son of one of the fathers of astrophysics, by Ledoux, the Belgian worker, by Miss Kluyver and Wesselink in Holland, by Biermann in Germany, and by Cowling in Great Britain.

What is the present position of the pulsation hypothesis? Rosseland chooses the wise course of not advocating any particular form of the hypothesis; but attempts to bring out the real difficulties involved and to develop general methods of attack capable of application whatever new observational features the future may have in store. To me it seems that the well-tried methods fail on the whole to account for the phase-relation in Cepheids. It seems incredible that the various causes of phase-lag treated by Rosseland and others should accumulate up to exactly a quarter-period, or that combinations of higher harmonics, or anharmonics, should yield simultaneously the observed asymmetry of the light-curve and the clear but unexpected phase-relation of the light-curve to the velocity-curve.

Rosseland nowhere mentions what appears to me to be the most striking feature of the observed oscillation, *qua* oscillation, namely, that in the course of the complete oscillation the star never passes through its associated equilibrium configuration—it cycles around it. This is utterly unlike the behaviour of oscillating systems in mechanics. Rosseland gives short shrift to my attempt to *begin* with the energetics of the oscillation, urging that since the solutions have not been derived so as to satisfy the hydrodynamical equations of motion, they need not represent mechanically possible motions. But 'mechanical' solutions have, on the whole, failed to represent the phenomenon. It might equally be urged against the mechanical solutions that the adiabatic hypothesis on which they are based is, as applied to a star, self-contradictory; for if the star is imagined to consist of adiabatically-walled cells of material, the normal flow of energy through the star, which maintains the luminosity, would also be inhibited. The solution in terms of energetics gives at once the asymmetry of the light-curve.

However that may be, Prof. Rosseland is to be congratulated on having produced an entrancing study of an entrancing subject, and on having opened far-stretching vistas in the mechanics and thermodynamics of oscillation theory. It may be added that the book is not confined to Cepheid variables, but treats also of long-period variables, cluster-type variables, variables of special types and novæ.

E. A. Milne

SCIENCE IN CHINA

Science Outpost

Papers of the Sino-British Science Co-operation Office (British Council Scientific Office in China), 1942–1946. Edited by Joseph Needham and Dorothy Needham. Pp. 313+24 plates. (London: Pilot Press, Ltd., 1948.) 25*s.* net.

THE core of this book consists of a series of articles on science in China which originally appeared in *Nature* during 1943–46. With them are reports on the first three years working of the Sino-British Science Co-operation Bureau (February 1943–February 1946), a broadcast from London called "Science and Life in Wartime China" (December 1944), Dr. J. Needham's original memorandum from Chungking on an International Science Co-operation Service (July 1944), and a reprinted paper on the Chinese contribution to scientific humanism. The original part of the book comprises the excerpts from letters, extracts from the logs of the north-west journey in 1943, of a journey on the Burma road in September 1944, of the south-east journey in April 1944 and of a journey in Shensi in October 1945, entries from the diary of Mrs. Needham, and a number of poems by Rewi-Alley, with two by Dr. Needham himself.

To this vivid material, in which the warm human sympathies of the Needhams are so clearly if unobtrusively displayed, the book owes its charm. Of the poems, no more need here be said than that Dr. Needham's "Poem for a Chinese Friend" and the translation of "The Ballad of Meng Chiang appear to convey the Chinese atmosphere most clearly. For the rest, the poems are less successful than the extracts in displaying the conditions under which the staff of the Sino-British Science Co-operation Office worked during these years, and the background against which the scientific workers and technologists of China sought to maintain and develop the ancient civilization of their country. An excellent series of illustrations contributes to the same end, while the list, which is appended, of 139 papers by Chinese men of science transmitted by the Office for publication in the West, shows that the flow of knowledge through the Office was from East to West as well as West to East.

As a travel book it should appeal to both the scientifically trained and the layman. Dr. and Mrs. Needham have compiled it to do justice to the achievements of the scientific workers and engineers of China. The book may have some further interest as giving, in a modest way, some indication of what is at stake in the present struggle in China, at least so far as science and technology are concerned. But it may, perhaps, take a more permanent place in the literature of science as a simple record of the human values of pertinacity, courage and sympathy on which the achievements of the Sino-British Science Co-operation Office are firmly based and which are demanded as the price of service no less in the field of science than in other fields of human endeavour.

R. Brightman

SCIENCE FOR THE LAYMAN

Into the Atomic Age

By Chapman Pincher. Pp. 158 + 36 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1948.) 9*s.* 6*d.* net.

A Study of Fishes

By Chapman Pincher. Pp. 304. (London: Herbert Jenkins, Ltd., 1948.) 15*s.* net.

A LITERARY problem which does not become less difficult with the increasing complexity of science is that of presenting recent discoveries in a form which is intelligible to the layman. Usually, when an author announces that he is writing a popular book on a scientific topic for the layman, it means that he is either writing a non-specialist book which will be of general interest to the specialist in some other subject, or he is writing a book which will capture the fancy of the general reading public because of the intrinsic interest of the subject itself.

It is to these two groups that Mr. Chapman Pincher appeals with his "Into the Atomic Age". As scientific correspondent to the *Daily Express* he has learned that the majority of his readers are more interested in bits of information about scientists and their lives than about science itself and, in his book, he has carefully blended some straight reporting on the theoretical, technical and military aspects of atomic energy with accounts of meetings he has had with leading atomic scientists in the course of his work. The lay reader is thus carefully led along the road where developments in atomic energy have been made by stages where stiff climbs on technical matters alternate with rests in which information about great men and their careers can be given. The whole book suggests that Mr. Pincher has not only studied his subject and the art of putting it over, but also the public whom he is trying to reach.

There is also a third group of the reading public for whom the scientific author tries to cater. This is the laity with strong interests in a particular hobby or craft and who are always keen to extend their knowledge of the hobby or craft. In "A Study of Fishes", Mr. Pincher sets out to provide scientific information for the angler which will add to his understanding and, by replacing some of the theories which rely more upon imagination than objectivity, improve his technique on the bank or shore. The book is thorough and contains much that will help the fisherman to understand practical points which he has picked up by experience and hearsay. It is doubtful if the author is wholly successful, however, for whereas topics like the bending of light, the dyeing of maggots, and streamlining should present no great difficulty, sections on breeding and pigments with strange words like genes and chromosomes and peculiar chemical formulæ of substances like melanin might prove to be very disconcerting. The frequent use of American names like killifish and squeteague is equally disturbing, and, although the name and usual location of strange fish can be found in a well-prepared list at the back of the book, the general reader is usually not adept at making frequent references to another part of the book. For him this is meant to be a work to read and not an encyclopædia. If these defects are eliminated in subsequent editions, there is little doubt that "A Study of Fishes" will become a book read and valued by many anglers.

T. H. HAWKINS

DEMOCRITUS OF ABDERA

Le dottrine di Democrito d'Abdera

By Federigo Enriques e Manlio Mazziotti. Pp. xxii+339. (Bologna: Nicola Zanichelli, 1948.) 1,500 lire.

FEDERIGO ENRIQUES, whose death at the age of seventy-one occurred in 1946, was one of the leading Italian mathematicians of our time; he is specially renowned for his joint creation, with Castelnuovo, of the invariantive theory of algebraic surfaces, which will remain one of the glories of Italian mathematics. As an example of versatility, moreover, Enriques was outstanding; for, over and above his purely technical achievement, which suffices to place him in the front rank, he maintained a lifelong interest in the history and problems of science which, in the "Encyklopädie", his books and articles on one hand, and in his lectures at Bologna and Rome on the other, earned him a second reputation. Above all, he was attracted to speculation concerning the Greek contribution to science, partly, no doubt, because the fragmentary nature of the evidence leads to fascinating conjecture.

At his death Enriques left two completed manuscripts, one (in course of publication) on the theory of surfaces, and the other on the atomist Democritus of Abdera (*c.* 500 B.C.). Knowing the man, one can readily appreciate the appeal of this theme—the reconstruction and interpretation, from stray sentences and commentators' allusions, of the thought of a philosopher whom Enriques esteemed among the greatest of the Greeks. The difficulty of the task is increased by the fact that no one can be sure how much of the fragments remaining to us is due to Democritus and how much to his master, Leucippus.

Like much of Enriques's work, the book is a collaboration, in which the arrangement and interpretation of the text is due to Dr. Mazziotti, the superstructure being largely Enriques's own. Each chapter deals with a particular aspect of Democritus's contribution to philosophy; it opens with a detailed and acute critique of the subject-matter from the modern scientific point of view, after which come the various classical texts (in Italian translation), accompanied, wherever necessary, by brief comment or explanation. All this material is arranged in thirteen chapters, which cover the whole field of Greek thought, from natural science and geometry to biology, logic and ethics. The masterly comments can be read and enjoyed for their own sake, irrespective of their bearing on the historical and technical problems which the author seeks to elucidate; and the book should, therefore, reach a wide circle of readers.

L. ROTH

VETERINARY PROTOZOOLOGY

Veterinary Protozoology

By Prof. Banner Bill Morgan and Prof. Philip A. Hawkins. Pp. vii+195. (Minneapolis, Minn.: Burgess Publishing Co., 1948.) 4 dollars.

THIS book has been written for veterinary students, practising veterinarians and agricultural students, and its scope is similar to that of U. F. Richardson's book reviewed recently in these columns (*Nature*, 162, 756; 1948). It is a useful book, full of practical information; but the size of its page (11 in. × 8½ in.) makes it rather inconvenient to handle, and its small type, clear though it is, is not read with comfort on a page of this size. Its illustrations, with the exception of the frontispiece, are all in line and stipple, and are all unusually large. Many of them are so much simplified that they lose much of their value. One cannot help thinking that a reduction of their size would have made a smaller page possible and would have released space for more of the useful text.

One doubts, for example, whether any reader will require a *Tritrichomonas* four inches in overall length; or coccidian oocysts on a similar scale, which do not show the spores and residual bodies which are essential if the figures of the oocysts are to be aids to diagnosis of the species. Photographs of oocysts are used in other books, and they give a much better idea of what is actually seen through the microscope. The frontispiece, a microphotograph of *Tritrichomonas fœtus* magnified until it reaches an illustrated length of 7½ inches, cannot be called a satisfactory representation of this species, and the diagrams of it printed elsewhere in the book are more useful.

The text of the book contains a great deal of valuable information. It begins with a brief general account of the Protozoa, which might have been more carefully worded. Of the Sporozoa, for example, the authors say that "Reproduction is by schizogony (spore formation)", a phrase which fails to distinguish between the asexual process of schizogony and the formation of spores after a sexual process. A similar failure to supply the biological basis of the veterinary specialist's work is evident in the statement that

"Reproduction" of the Ciliata "is mainly by conjugation; asexual reproduction by binary fission occurs"; and in the definition of the reservoir host as "a host harboring parasites which may be transferred from man to domestic animals", a statement which is inadequate even in the restricted field of veterinary protozoology.

Criticisms of this kind do not, however, apply to the greater part of the book, which gives a detailed and valuable account of the Protozoa that cause diseases of farm stock, and of the symptoms, diagnosis and treatment of these diseases. The hosts considered in turn are horses, cattle, sheep and goats, swine, dogs, cats and the 'fur-bearers', namely, the fox, rabbit and mink. *Tritrichomonas fœtus* and the disease it causes receive considerable attention, and there is, at the end of the book, a diagram of a plan for hygienic breeding designed to eradicate bovine trichomoniasis and also, in the useful section of the book on diagnosis of protozoal infections, a large plate of diagrams of Protozoa likely to be encountered when trichomoniasis is being diagnosed. Another plate illustrates the not very complex instruments used by the authors for diagnostic work. Some of the space given to these plates might well have been given to structures, such as seeds and fragments of various kinds of foods, which may resemble coccidian oocysts and dying or degenerate Protozoa in the fæces. Even a reduction in size of the figures would have made this possible.

Workers who have difficulty in obtaining the literature of this subject will find a good summary of it in this book, and also a bibliography, extending to 18 pages, which includes important books, a list of the circulars and bulletins on protozoal diseases issued by the United States Bureau of Animal Industry and Department of Agriculture respectively, as well as references to 309 research papers. There are also useful host-parasite lists, schedules of treatment and a brief article on the International Rules of Zoological Nomenclature.

G. LAPAGE

NON-LINEAR WAVE MOTION

Supersonic Flow and Shock Waves

By R. Courant and K. O. Friedrichs. (Pure and Applied Mathematics, a Series of Texts and Monographs, Vol. 1.) Pp. xvi+464. (New York and London: Interscience Publishers, Inc., 1948.) 42*s*.

TWENTY-FIVE years ago what was known on the dynamics of gases, if acoustics and the study of steady motion at speeds small compared with that of sound (when the flow resembles that of a liquid) be omitted, could have been expounded in a few dozen pages. Since then, and more rapidly since 1943, the subject has grown into one which no single book can describe in its entirety. The primary stimulus was the increase in aircraft speeds; but a secondary stimulus, the belated realization of workers in pure science that the phenomena show fascinating differences from those of classical physics, has become equally important.

Profs. R. Courant and K. O. Friedrichs have not sought to cram into their review of progress in this field a vast mass of detail in an attempt to be comprehensive. They have chosen rather to present certain parts of gas dynamics, in a leisurely style, so as to make the result essentially a study in non-linear wave motion and the propagation of waves of discontinuity; there are appendixes on analogous physical problems, including waves in elastic-plastic materials. Engineers can go elsewhere for rule-of-thumb procedures, for accounts of experimental methods, or for the very extensive and valuable linearized theory of supersonic flow. The man of pure science may regret, however, the almost complete absence of reference to viscosity as an important property of gases.

Prof. Courant is the author of the celebrated "Methoden der mathematischen Physik", Vol. 2, which includes, in a precise and unified whole, a very large mass of general theory relating to partial differential equations. The present book incorporates from that work much of the theory of the quasi-linear hyperbolic problem. The preface regrets that a similar unification and completeness are impossible throughout the present subject, still in its infancy. The reader must rejoice, however, that the authors have not excluded special, more involved, methods which are as yet imperfectly known, since the frontiers of science are often thus isolated, and the interest of the fighting scientific worker lies mostly in such regions. In much of this we see the pen of Prof. Friedrichs, a doughty explorer of new paths.

The book is discursive, and aims principally at communicating the type of mathematical and physical behaviour encountered. It is not a reference work, so it should be read straight through, perhaps fairly fast. The clever student who does this, fresh from an undergraduate course of classical (linear mathematical physics, will be led safely into a clear understanding of what is now known on the non linear wave problems involved. Some of the ideas are complicated, and the pages of 'talk', free from formulæ, will be found among the most useful.

Unsteady rectilinear motion is covered very thoroughly, more so than in any previous book, and much of the critical work is done here, since the equations are fairly tractable in terms of Riemann's variables, while the deduced behaviour can mostly be taken over into more complicated systems. Thi work includes an extensive section on flame propagation.

Plane steady supersonic flow is then treated more briefly; its behaviour is qualitatively almost identica with the unsteady rectilinear motion if the second spatial dimension is equated to the time. The 'limi line' is put firmly in its place (below the importance attributed to it by some); its connexion with the hodograph transformation is displayed, though otherwise the latter is developed only for the purpose o finding simple exact solutions and for the graphical method of Prandtl and Busemann.

Shock reflexion is treated thoroughly. To reconcil theory and experiment on 'Mach reflexion' various postulates put forward include an expansion wav centred at the three-shock intersection. The Lava nozzle is discussed in detail, and it is shown what variety of shock configurations are possible therein as explanations of phenomena observed in choking and otherwise. A short section on axi-symmetrica flow and spherical waves, 198 references and an inde conclude the book.

The book, compiled and improved over a numbe of years, and given limited circulation in an earlier shorter form during the War, is most careful and accurate in its statements. However, in Fig. 41 the rear shock should curve in the opposite sense.

M. J. LIGHTHILL

Henry A. Ward, Museum Builder to America

By Roswell Ward. Edited by Blake McKelvey. (Rochester Historical Society Publications, Vol. 24.) Pp. xxiv + 297 + 15 plates. (Rochester, N.Y.: Rochester Historical Society, 1948.) N.p.

PROBABLY no individual has contributed more to the development of natural history museums throughout the world than Henry Augustus Ward, of Rochester, New York, who, even in his boyhood days, had acquired a roving disposition. At an early age he developed a keen interest in geology, and by dint of persistent hard work coupled with exceptional and unexpected opportunities he attained a position of eminence when he was comparatively young.

Early in the second half of the last century his passion for travel and for collecting rare specimens brought him to Europe, where he visited every museum he could find, returning to Rochester at the age of only twenty-seven with the finest collection of geological specimens in America. But this was only the beginning, and his love for exploration and the acquisition of new exhibits lured him to all parts of the world and provided geological and zoological specimens for Ward's Natural Science Establishment, which soon became a great emporium for the distribution of natural science material. Not only was this establishment famous for the provision of outstanding exhibits which led to the formation of many natural history museums, particularly in America, but it also became a training ground of outstanding men in various branches of museum technique who afterwards graduated to positions of eminence in the museum world. The later years of Ward's life were devoted to building up the most complete collection of meteorites in existence, a collection which is now preserved in the Field Museum, Chicago. The biography has been admirably written by his grandson, who has given us a complete and fascinating account of the life, work and achievements of a remarkable man of science, explorer and collector.

H. Shaw

Was ist Wahrheit in den Naturwissenschaften ?

Von Bernhard Bavink. Pp. 88. (Wiesbaden: Eberhard Brockhaus Verlag, 1947.) n.p.

IN this little book Prof. B. Bavink discusses first the meaning of 'truth' in science and, secondly, he criterion by which we determine what is true and what is false. On the first point he contrasts the ealistic view—that there is an external world which we examine and that our description of it is true if it corresponds faithfully to that world—with the positivist view that there is no world independent of our observations and that a statement about our observations is true if it is consistent with them all. As a compromise between these extremes he cites the Kantian doctrine that there is an external world but hat it is unknowable and all our knowledge is of our xperience. Prof. Bavink considers these attitudes in their relation to both general and particular scientific laws. Without definitely adopting any of hese views he points out that in practice we usually hink in terms of the first, and that in any case we must admit that scientific laws hold independently of the knowing subject. In the matter of the truth criterion he discusses the belief that mathematical and scientific theorems are conventions, and gives reasons for rejecting the positivist attitude in this matter. He finds the criterion of truth with respect to a scientific law in the convergence of different, and apparently independent, lines of research towards the same conclusion; the law is true in so far as this convergence is without exception.

While the book does not contribute anything essentially novel to the problems of which it treats, it is clearly and interestingly written, and sets out the various considerations in a thought-provoking manner. It may be recommended as a valuable stimulus to those whose minds are not yet made up on the subject.

H. D.

Einführung in die vergleichende Morphologie der Wirbeltiere

Von Prof. Dr. Adolf Portmann. Pp. 335. (Basel: Benno Schwabe und Co., 1948.) 28 Swiss francs.

DURING the nineteenth century many detailed works on comparative morphology were published, both for vertebrates and invertebrates. At the close of the century, morphology was frowned upon by the eager physiologists, experimental biologists, embryologists and geneticists, who maintained that morphology was worked out. But as usual the pendulum has swung back again, and there has been a realization that morphology is the fundamental study upon which the others are based, and that not less but more is needed.

Prof. A. Portmann's book is an up-to-date treatise on the elements of comparative morphology, based on a wide, accurate and detailed knowledge of the vertebrates. The work follows the usual course, dealing with the systems and organs of the body in turn, discussing their homologies, comparing fossil and modern examples, and assessing the value of their evolutionary trends. The excellent figures prepared by Frl. M. Stehelin are especially to be commended. Their very simplicity is pleasing, and her bold use of black and white is applied with an artistic merit rarely seen in text-books. The parts of diagrams in comparative series are numbered instead of lettered, so that the reader can test his knowledge. Is it to prevent his memorizing the numbers that in one series the numbers begin at the anterior, and in another at the posterior end ? A selected list of modern works is intended as an introduction to the literature, and there is an index.

N. B. Eales

Introduction to Emulsions

By George M. Sutheim. Second printing. Pp. viii + 260. (Brooklyn, N.Y.: Chemical Publishing Co., Inc.; London: Chapman and Hall, Ltd., 1947.) 21*s.* net.

THIS book is written in the first person in lecture style, and is, in fact, based upon lectures given at the Brooklyn Polytechnic Institute in New York. It is claimed to be written by a practical man for practical men, and, on that account, contains details and explanations which the chemist with a university degree will find superfluous. A bibliography is appended with 159 references; but no mention is made of G. I. Taylor's work on the physics of emulsion formation, nor of F. A. Cooper's work on size frequency analysis and the chemical engineering aspects of emulsion manufacture. Another extensive appendix gives the commercial name of 182 emulsifying agents produced in the United States, and lists their chemical name or formula, group and emulsion type and manufacturer. The uses of bentonite as an emulsifying agent is only lightly considered. The manufacture of a good emulsion is still somewhat of an art, and the comment that "you cannot learn to ride a bicycle by reading a book" still seems to hold for practical emulsion technology.

M. B. Donald

LIGHTNING AND SPARK PHENOMENA*

By DR. T. E. ALLIBONE, F.R.S.

Research Laboratory, Associated Electrical Industries, Ltd.

THE study of lightning has been allied to the study of the electrical spark discharge since the dawn of experimental science. Benjamin Franklin, the 'father of lightning', performed with electricity drawn from thunderclouds the same experiments that could be performed with electricity generated by a frictional machine. Hoffert demonstrated the multiple character of the flash by photography in 1889, and a few years later Walter showed that the electric spark could have a similar characteristic if the circuit constants were suitably chosen. In later years Schonland's extensive researches in South Africa, with the aid of the high-speed rotating camera, have greatly extended our knowledge of the lightning flash, and similar physical characteristics to those he has described have been found in the high-voltage spark discharge. Knowledge of both phenomena is, however, far from complete; but as lightning occurs so infrequently in Britain under conditions suitable for observation, it is perhaps more profitable in this country to contribute to the understanding of lightning by the indirect method of studying spark phenomena.

Sir George Simpson[1] made one of these first contributions, from which he deduced the polarity of thunderclouds. He observed the marked difference between the positive and negative streamers which pass between dissimilar electrodes charged from a Wimshurst machine—when the more highly stressed electrode was positively charged, sparks branched away from it; but when negatively charged, strong unbranched discharges passed between electrodes. On examination of more than four hundred photographs of lightning, he found more than 50 per cent exhibited branching away from the cloud and only three towards the cloud; 25 per cent showed unbranched discharges, but he recognized that branches on these might have been obscured by cloud or rain, so that at least a safe generalization was that the majority of flashes emanate from positively charged clouds.

This deduction was directly opposed to evidence of field changes at various distances from lightning flashes; Schonland and Craib[2], Wormell[3] and others following C. T. R. Wilson's pioneer work found the majority of lightning flashes brought a negative charge to ground, and Schonland correlated this with visual observations that a high percentage of these flashes branched downwards from the clouds. He also measured the magnitude of the point-discharge currents beneath a thundercloud and found these to be of such a polarity as to leave a positive space charge over the ground. This conflict of evidence prevailed until 1931, when the matter was resolved by a series of observations of spark discharges from a one-million volt generator in the High Voltage Laboratory of the Metropolitan-Vickers Company. Simpson's observations had been made with perhaps 50–100 kV. sparks; at much higher voltages the difference in appearance between sparks of opposite polarity is not nearly so marked as at low voltages, and frequently extensive branching of a negative discharge can be seen. The conditions for this were determined[4]; if an extensive positive space charge is built up in advance of the negative streamer, the latter will branch just as profusely as will a positive streamer, and then, to a first approximation, no difference can be observed by eye between positive and negative discharges. The fact that Simpson and many others observed a high preponderance of branched lightning discharges does not, therefore, imply that the discharges are of positive polarity.

Two years later, Schonland began his extensive researches into the nature of the lightning discharge as photographed by the Boys camera with rotating lenses. These showed the existence of a low-intensity discharge which travelled slowly from cloud to ground, followed by a high-intensity return stroke from ground to cloud, the speed of propagation of the latter being some 10–100 times that of the 'leader stroke', as Schonland named the pioneer discharge. This time interval between the initial appearance of the leader stroke leaving the cloud and the return of the 'main stroke' to the cloud immediately appeared analogous to the 'time-lag of flashover'[5] of a gap, so familiar to scientific workers engaged in transient electrical researches, and a search for the 'leader stroke/main stroke'[6] sequence in the laboratory with the aid of a rotating film camera was made. Sparks 40 in. in length were photographed with a camera capable of resolving times of the order of one microsecond, and the photographs showed unmistakably that as soon as the high-voltage source was connected to a point electrode, a discharge developed from this to ground, while a few microseconds later a fresh discharge passed between electrodes carrying such a large current that the potential of the point fell to very low value; the oscillograph showed that the 'time-lag of breakdown' was identical with the time interval between the onset of discharge and the occurrence of the main stroke as recorded photographically. Schonland described the leader stroke as a faintly luminous downward-moving streamer travelling with a speed of about 10^7 cm./sec.; when the ionized path is continuous between cloud and ground, a brilliant upward-moving streamer develops from ground to cloud at 10^9 cm./sec. From these early spark photographs and corresponding oscillograms, it was deduced that the leader stroke travelled between the electrodes at about 10^7 cm./sec., but the camera was unable to give information as to the speed of the return stroke.

The above results in the laboratory merely confirmed that sparks behaved in a manner similar to lightning flashes; but they were obtained for positive *and* negative discharges, whereas only negative lightning flashes have been observed with the rotating camera. The laboratory sparks were produced by the discharge of a condenser, and the way they were affected by the circuit constants was studied[7]. It was found that with large values of circuit resistance the 'leader stroke' in its progress from the high-voltage electrode to ground was reinforced intermittently by fresh charges brought from the high-voltage source, the time interval between these stepped processes being a measure of the recombin ation of ions. Undoubtedly the stepped process also depended upon the circuit resistance and therefore on the time-voltage characteristic of the applied potential, so that it is arguable that the stepped character of the lightning leader stroke may also be due to the 'resistance' of the current-carrying path within the cloud. More laboratory work is needed to give a better understanding of the advance of the leader stroke.

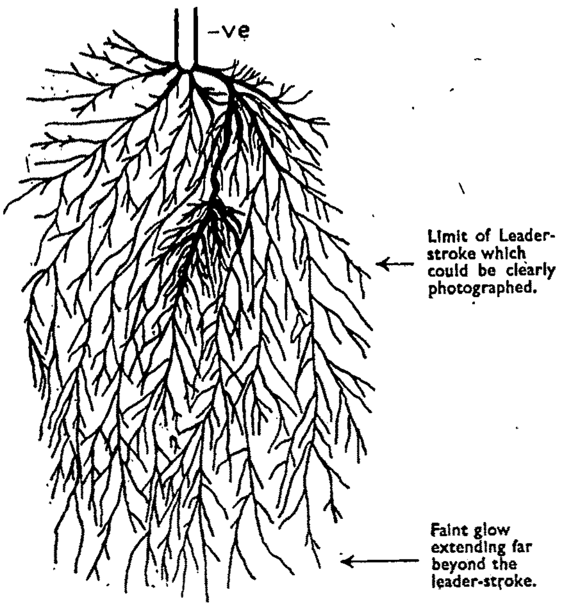
---

* Friday Evening Discourse at the Royal Institution, delivered on March 12, 1948.

An interesting difference was found between the positive and the negative discharge[8]. In general, the positive leader stroke progresses most of the way from a high-voltage (positive) point electrode to a grounded plane electrode; but in general as a negative leader stroke progresses from a high-voltage (negative) point electrode, it is met in mid-gap region by a positive leader stroke rising out of the grounded plane. If the field-strength at the positive grounded electrode is artificially increased—as by providing pointed electrodes projecting from the grounded plane—the upward positive leader stroke development is favoured, and the meeting point between the two leader strokes is raised nearer to the negative electrode, until, if the grounded positive point is high enough above the plane in relation to the inter-electrode gap, the positive leader dominates the picture to the almost complete exclusion of the negative leader from the high-voltage electrode. If this is true also for lightning, discharges at the top of high buildings should be predominantly discharges *from* the buildings to cloud[8]; this phenomenon was, in fact, observed from the top of the Empire State Building, New York.

This same characteristic must be the cause of the prevalence of a high percentage of negative discharges being recorded on transmission lines; the advancing lightning flash, if of negative polarity, is 'attracted to' a high tower or line by virtue of the ascending positive leader stroke rising from the line to meet the flash. There are in existence a number of photographs of lightning which provide evidence in favour of this, though no actual record exists taken by a rotating camera of flashes to towers or moderately tall buildings; the deduction is based primarily on the laboratory spark photographs, and the only doubt lies in the exact magnitude of the effect on the statistics of lightning strokes to lines.

Further work by Schonland and his co-workers established the fact that the leader stroke discharge was a complicated process; a streamer develops from the cloud in a series of steps separated in time by about 50 microseconds, and at each step the discharge is advanced towards ground by a discharge path more luminous than the remainder of the discharge; it was suggested by Schonland[9] that the steps were preceded by a 'pilot' streamer, too feeble to photograph, advancing continuously from cloud to ground with a speed of about 10^7 cm./sec. As mentioned above, whether it advances continuously or not may depend on circuit constants, but whether it exists or not is of great interest.



-ve
Limit of Leader-stroke which could be clearly photographed.
Faint glow extending far beyond the leader-stroke.

Development of pilot streamers ahead of the 'leader stroke' to the spark discharge

Now it had been known for many years that not even quartz lenses and fast photographic plates could record all the details of a spark which can be seen by eye. For example, in the 1931 experiments[4] on branching of negative discharges, a technique had been used of arresting the discharge by providing in the circuit an alternative spark path having a time-lag of spark-over just a little shorter than the time-lag of the gap under close observation. Under these conditions the great glare of the spark is eliminated from the gap, across which only a partial spark is developing, and a most extensive tracery of discharge was visible to the eye but not recorded photographically. In a recent effort to establish the existence of the 'pilot' streamer, these old experiments were repeated[10] with a new photographic technique; bromide or gaslight printing paper was set up in a vertical plane between the high-voltage electrode and ground, so that the arrested discharge played over the surface of the paper and left a latent image. This probably was as extensive as any discharge the eye could see; a very extensive fine tracery was recorded many inches ahead of the 'leader stroke' which the rotating film camera could record, and the leader stroke is now discernible, not as a discharge advancing into virgin air, but as a canalizing of the tenuous discharges, possibly when the current density reaches a certain value. The accompanying sketch taken from one of the photographic prints shows the details better than can be brought out by direct reproduction of the original prints. Clearly this tracery could never have been detected in the lightning flash photographs, but it provides very strong evidence for the correctness of Schonland's 1938 postulate of a pilot streamer. With what speed this diffuse discharge advances into the virgin air is not known, nor at what current density the canalization of the discharge occurs; and much more experimental work in the laboratory is needed to take the subject a step further.

Another problem of the thundercloud which can be studied in part in the laboratory is the potential necessary to cause breakdown. Early estimates of potentials of clouds with respect to ground were based on the known breakdown potential of air between pointed electrodes at rather small spacings; but there is insufficient information about the breakdown potentials of very large gaps to say whether the same gradients are necessary for a discharge to start. What information exists relates to impulse voltages, but the breakdown laws under constant voltages would be much more interesting, since breakdown within the cloud must begin by discharge between oppositely charged volumes of cloud maintaining their charge steadily for some seconds at least.

(The Discourse was illustrated by a number of experiments with a 500,000-volt impulse generator; in the darkened auditorium the positive and negative leader strokes were shown at different stages of development, the influence of electrode shape on leader strokes was demonstrated, and examples of the 'protective action' of a pointed electrode on the space around it were shown. The influence of the nature of the terrain on the incidence of lightning was illustrated with a sand tray model.)

THE HISTORY OF ALUM

A HISTORY of almost any common material could be made the framework of a general history of civilization, both in its political and economic aspects, and hence could serve as a kind of heuristic method of teaching general history. This would be a very uneconomic method, since every specialist author would have to repeat a large mass of material already traversed by every other author; and it may be suggested that a historian of science or technology might profitably assume that the political history (taking the name in its widest sense) with which his studies bring him more or less intimately in contact can be sought elsewhere. There are notable exceptions to this; some works on the history of science, such as Meyer's "Geschichte der Botanik", deal in detail with various aspects of general history in a way which makes them still very useful to the professional historian when he happens (as is rarely the case) to know of their existence. The history of alum is a subject which lends itself very well to a plan of fitting it into a general picture of the conditions and movements of the times traversed, and an author working up this subject has a good opportunity of doing this if he feels inclined towards it. It may be said that Dr. Charles Singer has, in fact, incorporated a substantial amount of such material, including a general history of the alum trade, in his recently published account*, and this will make it especially valuable and interesting to the general historian.

An author taking up a study of the history of a material will find that his subject will fall into one or other of three large groups. In the first, the basic information is already well known and exists in adequate detail; such, for example, would be the history of iron. In the second, practically no coherent and collected information is available, and the author is compelled to go through an immense number of likely and unlikely sources, assemble a mass of unconnected and generally contradictory statements, and then attempt to reduce the material to some kind of order, carefully avoiding any tendency to arrive at general conclusions before this has been done, so as to prevent the possibility of making a framework into which the material must, at all costs, be fitted. In the third group, the material has already been treated, but imperfectly and often at a date when important information relevant to it was not available. It may be suggested that the history of alum belongs to this third group. Its main outlines have been drawn by such authors as Beckmann and Heyd, and the main sources to which a modern author might turn for his materials have been stated by them. It is then essential to re-examine the data and, in completing it and adding what is new, to draw more correct conclusions. Beckmann, for example, although he makes use of nearly all the material now available, drew a completely incorrect conclusion from it, namely, that alum was unknown in antiquity.

The history of science can be presented in various ways. Those who have read the previous publications of Dr. Singer will be aware of the general guiding principles which he follows, and will know what to expect. An author may confine himself to an account of his subject proper, or he may include what may be called the external machinery of science, such as the foundation and growth of scientific societies, the relation of the personalities with whom he deals with religion or politics, when they happen to have had such relation, and in such cases to deal with these wider aspects of the subject. Some sciences lend themselves more easily to such treatment; astronomy in particular is one, and such personalities as Galileo offer an almost inexhaustible plenitude for repetitious treatment in such a way. This type of writing, however, is more suited to the general historian, or the author who sees in the history of science an opportunity of conveying to his readers, many of whom he may hope are relatively uninstructed, his cherished beliefs or creeds. Such writing is not in the category of history of science proper, and does not advance in any way the study of this subject.

In his publications Dr. Singer has followed a middle path. He has available a wealth of detailed knowledge such as the specialist would use in producing a severely professional account of the subject, and at the same time he has a feeling for the picturesque and attractive marginal aspects, in particular of the value of illustrative material, which make his works so attractive and readable. Much of this material is drawn from little-known and inaccessible sources such as manuscripts or books, the existence of which is unknown to the general historian of science. In the present work, in the preparation of which Dr. Singer has been fortunate in being able to draw on such sources, he has given a selection of illustrations, including many in splendid colour, which puts the book into a class of the highest interest, and makes it, even to those not much drawn to the general story of alum, one which must have a lasting value as a fine book, in the production of which the artistic craftsman has played a notable part. In the appearance of the book, as a book, everyone concerned must take a justified pride. Dr. Singer always takes care to accompany every illustration with an adequate description, and this feature of his authorship is fully continued in his latest work.

The book is divided into five main parts: antiquity, medieval technical and chemical lore, medieval trade, monopolies and empirical methods, and the rise of scientific industry. As stated above, although the guiding theme is the history of alum, an opportunity is taken in each section of presenting information from other departments of knowledge, which makes it, in itself, a valuable source for the student of each period as a whole, although the quotations from texts are, in the main, those dealing with alum. There are 361 references collected at the end of the book, an arrangement which, although perhaps necessary on æsthetic grounds, is very inconvenient to the reader in search of information. There has been a tendency among old-fashioned authors, particularly in Britain, to show a degree of shame in exhibiting detailed knowledge; this is perhaps a relic of their own school days, when such accidentals of scholarship were looked upon with disfavour. Such reticence is out of place in modern works on the history of science, when precise documentation is necessary and expected. Dr. Singer, as usual, takes a middle way, giving us in many cases only the title of the work, without a page reference. His bibliography is very satisfactory; only in one or two cases would one have wished for slight additions, as when he refers to D'Arcy Thompson's "Glossary of Greek Fishes" for the murex and omits to mention the special treatise by Moatsou (Alexandria, 1932); but even the narrowest specialist will find himself baulked at every turn in his search for omissions of sources in Dr. Singer's impressive list.

---

* The Earliest Chemical Industry: an Essay in the Historical Relations of Economics and Technology illustrated from the Alum Trade. By Charles Singer. Pp. xviii+337. (London: Folio Society, 1948.) £10 10*s*. 0*d*.

A reviewer is expected to find at least a few faults with every work, and to show good faith to his kind, the present writer will hurry over a few slight trivialities of this sort. The *bain Marie* of the Greek-Egyptian chemists was not a water-bath, and the original figures of the *kerotakis* would have been better than the supposed reconstructions (p. 10); *trichitis* (p. 19) is not alum, as the author knows in another place; *realgar* is not red sulphide of mercury (p. 52); 'saturated alkali' (p. 39) is probably ferrocyanide. Agricola was not a technological expert and cannot be expected to understand all he describes, and his portrait is not contained in any original edition of his book the reviewer has seen (pp. xv and 227); phlogiston is named before Stahl's work of 1703 (not 1702, as stated) (p. 249), and the dephlogisticated part need not be a 'fixed' body—in sulphur it was sulphuric acid; Lavoisier did not think the alkalis were oxides of unknown bases (p. 267); Davy's first name for potassium was 'potasium' (p. 268); Wöhler's aluminium was not very impure, and the metal was also obtained by Ørsted in 1826 (p. 268). These are all trifles. The style of the book is clear, concise and attractive; only in one or two cases has the author been hypnotized momentarily by his text, as in the Germanic "they dyed always the yarn before weaving" (p. 265). The reader should not omit to look up the references, where additional information is often to be found.

The story presented by Dr. Singer is, in brief, the following. Alum was known to the ancient Egyptians and Assyrians, who used it medicinally and in magic. Its use as a mordant in dyeing is described at least as early as Pliny (who, by the way, gives the first record of galls as an indicator long before Fallopia, p. 244), and from that time the history of dyeing is intimately connected with the history of alum, so that the book is valuable to those interested in dyes. It is shown that knowledge of chemical substances in the classical period was much more extensive than is sometimes thought, and not a few, alum notably, were known in quite reasonably pure condition. An account of ancient baths is given. Puteoli (modern Pozzuoli, on the Bay of Naples) was a source of alum, its baths long being famous. The information about technical arts in the medieval period is drawn from several treatises compiled in that period by non-literary authors, giving recipes for dyeing, etc.

After a concise account of Arabic alchemy (in which the strange difference between the "Secret of Secrets", an alchemical work thought to be by al-Rāzī, from his medical works is not noticed), and its continuation as the so-called Latin alchemy, Dr. Singer deals with lapidaries and handbooks such as the "Hausbuch" and the problematical "Plictho". A long and detailed account of medieval trade brings together much information about the rivalry of the Italian centres. In this period the import of alum from the East increased, although European alum, less esteemed than the Asiatic, was still made in significant amount. Exports from the Eastern Mediterranean, Phocœa, and the Black Sea became important, and there is an interesting account of Phocœa in Pegolotti. The rise of Venetian trade under a grant of privileges in the Byzantine imperial domains is linked with the influence of the Crusades. In the fourteenth century Florence had a trading supremacy, and the connexion between alum and wool turned a new corner on the way of technology and trade. Western sources of alum were now productive.

In 1461 large quantities of alunite, a mineral from which alum can be made, were found at Tolfa in Papal territory, and the famous Papal alum monopoly was established mainly by the efforts of Giovanni de Castro and Pope Pius II. The profits of the trade helped to subsidize the war against the Turks. The purchase of 'infidel' alum was anathematized, and indulgences were based on such motives. It is perhaps not generally known that the famous indulgence on which Luther acted was of this character. The monopoly of the Papal alum factory was later broken by the northern countries making alum from other sources. A financial contract between the Medici and the Apostolic Chamber in 1466 began a period when alum was not infrequently mingled with the hopes of mankind for felicity in the hereafter. This story of the Papal monopoly is fairly and clearly told; it had interesting ramifications. The works at Pozzuoli are well described, the illustrations of this volcanic region being most interesting. Some splendid coloured plates are reproduced from the work of Sir William Hamilton, who visited the district in his capacity of British Ambassador to Naples in 1764, as well as an interesting drawing by Madeleine Hortemels (aged seventeen) of the Grotto del Cane in a guide book of 1707. For this source of alum we have the well-known book "Metallotheca" by Michele Mercati (1717).

The working of alternative European sources of alum in the seventeenth and eighteenth centuries is described, with an interesting excursion on the history of mining (which is just beginning to pass out of the second category mentioned at the beginning of this review) and mineralogy, including mineralogical collections and museums. Alchemy was now giving way to chemistry, and for that reason the alum industry, which is perhaps the earliest chemical industry of all, could become scientific. Dyeing also became scientific, and the description of the sources and uses of the natural dyes is one of the most interesting sections of the book. The British alum industry had its rise in the exploitation of the carboniferous shale of the Yorkshire coast and Scotland. Peter Spence (1806–83) was the pioneer of this industry, and his descendants are among the premier alum manufacturers of the world. The preface of Dr. Singer's book, by Mr. Derek Spence, explains how it was wished in 1946 to celebrate the hundredth anniversary of the company by a lasting memorial to Peter Spence, and the present splendid volume is the result. In achieving their object they have at the same time, thanks to the unrivalled knowledge and literary skill of Dr. Singer, added a lasting contribution to the history of science for which they deserve the warmest thanks of all those interested in its welfare. This book will take its place among the great classics of the subject. J. R. PARTINGTON

OBITUARIES

Dr. A. D. Imms, F.R.S.

AUGUSTUS DANIEL IMMS, who died on April 3, 1949, at the age of sixty-eight, was well known to zoologists and entomologists throughout the world, and there are few, if any, modern zoological text-books with a wider circulation than his famous "General Text-book of Entomology". Imms graduated at Birmingham in 1903 and shortly afterwards went to Christ's College, Cambridge, as an 1851 Scholar. Here he obtained a B.A. degree by research in the days before the institution of the Ph.D., and came much under the influence of Dr. David Sharp and Sir Arthur Shipley. From being an assistant demonstrator in zoology under Prof. Gamble at Birmingham, he went to India in 1907 as professor of biology in the University of Allahabad. Later he was for three years forest zoologist to the Government of India.

These seven years in India influenced profoundly his further development as a zoologist, adding to his sound morphological attainments breadth of view in biology and an understanding of the complexity and urgency of the problems of agricultural and economic zoology in the tropics. While in India, Imms produced his best research work, among his papers at this time being a fine study of the morphology and biology of *Archotermopsis*, a primitive member of that most fascinating group of insects, the termites, the stupendous colonies and elaborate social organisation and caste system of which have been the marvel of zoologists since the end of the eighteenth century when entomologists first began to explore systematically the faunal riches of the tropics.

But it was not as an original investigator that Imms was to make his real mark. In 1913 he returned to England as reader in agricultural entomology in the University of Manchester, and he there commenced work on the great "General Text-book" already referred to. This was held up by the First World War and was not finished until 1925, by which time its author was chief entomologist at the Rothamsted Experimental Station. The text-book, a monumental work, has gone through many editions; it is in every way comparable with and in many respects superior to its famous predecessors, Packard's "Text-book of Entomology" (1898), Henneguy's "Les Insectes" (1904) and Berlese's "Gli Insetti" (1909). In this book Imms found full scope for his particular combination of qualities: an encyclopædic knowledge of his subject, a meticulous accuracy, a sound morphological insight and a well-balanced critical faculty. Indeed, it is the critical acumen and the balance of the book which are perhaps its most outstanding features, although the balance was somewhat upset in later editions by the immense growth of physiological investigation, a field in which Imms was less especially interested and which he left to others to summarize in text-book form. Imms was also the author of other valuable books, notably "Recent Advances in Entomology" (first edition 1930) and "Insect Natural History" (1947), and he produced the excellent articles on entomology in the "Encyclopædia Britannica".

Imms was elected a fellow of the Royal Society in 1929, and in 1931 he went to the Department of Zoology at Cambridge as first incumbent of the newly created readership in entomology. Here he built up a new sub-department and, during his time as reader, served on the Council of the Royal Society. He was president of the Royal Entomological Society of London and of the Association of Economic Biologists. When the main burden of text-book writing and the work of organising the sub-department was ended, Imms returned once more to personal research, and produced some valuable memoirs bearing particularly on morphological problems fundamental to questions of the ancestry of insects and phylogenetic relationships of the main orders. These included work on the growth processes in insect antennæ, on the constitution of the maxillæ and labium in the Mecoptera and Diptera—a study which throws a great deal of light on the relationships of the latter order—and an admirable short paper on the biology and relationships of that most puzzling insect *Braula cæca*, the 'bee louse'.

Personally Imms was reserved, and probably few people knew him intimately. Although he stimulated an immense quantity of valuable research through his writings, he was sometimes apt to appear discouraging to undergraduates, seeming on occasion to dishearten and chill by an apparent lack of enthusiasm. But in reality he was an excellent judge of promise in young research workers; he knew the real investigator directly he saw him, and he recognized and appreciated the type which would respond to criticism in the right way and whose ardour nothing would damp. A student of this quality could count on him for unswerving support and friendship.

Imms was elected a Fellow of Downing College in 1940, and his work for the College and his relations with its society constituted perhaps one of the happiest episodes of his career. When the Second World War came and the younger Fellows of the College left for war service, he unhesitatingly undertook the arduous duties of bursar and steward, thus entering on work with which he was previously altogether unfamiliar. Nevertheless, he made a real success of it and impressed all his colleagues with the rapidity and efficiency with which he got things done; he was particularly clever in making the most of the scanty time at his disposal, and it was astonishing how he contrived to carry this heavy burden of College work without apparently decreasing the time available for his scientific activities and without ever becoming in the least 'ruffled' over the sometimes irksome jobs which arose in the course of his duties. On his retirement from the University readership in 1945, Imms received the honour of election to an honorary fellowship at Downing. He was also honorary member of a number of learned societies in foreign countries, including France, Holland and Finland. The climate of Cambridge never suited Imms, and on retirement he therefore settled in Devon in the hope that he would enjoy better health there. He soon began to take an active part in local affairs and to enjoy his garden and the new duties and obligations which life in a small rural community involved. But further illness soon supervened, and his last years were, in the main, a brave struggle against persistent and painful ill-health, in spite of which he managed to accomplish much valuable work in the way of revising and preparing new editions of his books.

Imms married in 1913 Miss Georgina Mary French, of County Tyrone, who, with their two daughters, survives him. W. H. THORPE

Mr. W. A. Knight

MR. WILLIAM A. KNIGHT, the first headmaster of Sexey's School, Bruton, who died on April 11 at the age of eighty-two, was known as a leading educationist. From 1903 for some years he was a member of the Somerset Education Committee; during 1920–25 he served on the first Burnham Committee; in 1924 he became president of the Incorporated Association of Headmasters; and in 1928 he was elected to represent the English secondary school headmasters at the Bucharest Conference. He was an honorary M.A. of the University of Bristol, honorary associate of University College, Reading, and a J.P. for Somerset.

The opening of Sexey's School in March 1891 was due indirectly to an Elizabethan, Hugh Sexey (or Saxey), the founder of Sexey's Hospital, Bruton, certain accumulated funds of this institution being appropriated for the purpose. The Right Hon. Henry Hobhouse was chairman of the school governors until 1930. Mr. W. A. Knight, a native of Castle Cary, was only twenty-four at the time of his appointment, and during the thirty-six years until his retirement in 1927 he developed a school with highly distinctive traits. Bearing in mind a fundamental idea of the promoters to impart a strong practical and scientific bias to the curriculum, the youthful headmaster became a pioneer in the development of science teaching in schools. General elementary science, natural history, chemistry, physics and botany all found a place in the curriculum. A generation or so later, the importance of biological science in schools received general recognition. Up to the present time numerous Old Sexeians (many of whom are now well known in science) have taken a leading part in organising and developing biological work in schools, universities and research stations, both at home and overseas.

Gradually, under Mr. Knight's guiding hand, the school became known in the provincial universities, at the Universities of Oxford and Cambridge, and in Continental universities: so quick in its own soil was this acorn from a native Elizabethan oak. The record of Sexey's School shows that a proper emphasis on science in school teaching need not exalt material values at the expense of the spiritual. It is likewise remarkable that so many of Mr. Knight's pupils have developed strong literary and artistic tastes. The diverse fields in which alumni of this school have achieved distinction include the Church, literature, public affairs and administration.

In this little school, with her native human material and "Somerset's green lanes around her", the gifted headmaster was able to find full scope for his remarkable ability as a teacher, his organising genius and his inspiring ideals of attainment and character. Under Mr. Knight's tutelage one learnt as much out of school as within its walls. How, for example, could one remain indifferent to local history and topography when botany rambles with him led to such fascinating haunts as Wyke Champflower, Kingsettle Hill, Stourton Tower, Godminster and Holywater Copse?

The perennial charm and stimulating force of Mr. Knight's personality had much to do with the success of Sexey's School. He took a vivid interest in his pupils and their doings, both at school and afterwards. His memory of anything concerning them was amazing. In an unsurpassed measure he earned and kept the esteem and strong affection of his pupils, to whom he was always a personal friend as much as the ideal headmaster. In the words of a versatile old pupil (R. W. Gregory), who achieved eminence as an electrical engineer:

> You made us men, we boys of your own breed;
> And like the glowing steel, our mother wit
> With cunning hand you hammered into shape,
> And tempered for keen service to our kind.
> You made our School; a thousand boys and more
> You showed the way of life; and thorough men,
> Through all the continents of mother earth,
> Hold you in honour.

JOHN READ

PRESENT-DAY educationists, if they had had the opportunity, would have studied with interest, and acclaimed many points in, the pedagogical approach and the school organisation of Mr. Knight; for in many ways it was unique. For example, he would never allow 'holiday tasks', 'lines' or being kept in school after hours as a means of punishment. Both monitors (as they were then called) and staff could punish by a system of exclusions—exclusion for a definite period (which varied with the crime) from the gymnasium, the museum, the reading room, the fives courts, and even from the class-room (out of school hours). So boys never ran the risk of their literary appreciation being undermined through having to write under duress interminable quotations from authors; they always enjoyed complete freedom during their holidays: but the 'exclusions' proved to be so inconvenient that any sensible culprit thought twice before repeating his offence.

The school year was also divided into four terms, so that half-term rests were not necessary, and fatigue was reduced.

Mr. Knight also seemed to have a genius for choosing his staff to the best advantage. He was not easily bemused by high academic honours; capacity for work and the full recognition of the value of *esprit de corps* played important parts when he made a choice. Mr. Knight himself recently told me that, other things being equal, he would not mind whether his assistant was a 'pass' or an 'honours' man. One of his assistants recently coined the expression "the Sexeian habit"—the habit for hard work.

As Prof. Read writes, his "memory of anything concerning [us] was amazing"; and whenever we met him afterwards (no matter how many years had elapsed between), he was the headmaster, we the boys. In 1947, when the school honoured me by inviting me to present the prizes on Speech Day (well-nigh a quarter of a century after I had left the school), he took my hand and, without so much as a 'how d'you do', said: "But you have changed; you were always so very thin".

He was a great headmaster to whom science owes a considerable debt. He had no time for 'frills'; he got on with the job. The present headmaster, Mr. W. E. Page, writing to me recently, said: "We buried him, as he wished, with a minimum of ceremony and in the presence of scarcely a dozen people. It was moving in its stark simplicity." L. J. F. BRIMBLE

Mr. J. Hornell

MR. JAMES HORNELL, who died at Hastings on February 24 at the age of eighty-three, was a pioneer. He was one of the first marine biologists and fishery naturalists to be employed as such, and his experience of the fisheries of warmer seas placed him in a unique position for many years. Educated in Scotland and at the University of Liverpool, his early experience was gained on a fisheries survey of the Channel Islands, where he met his wife. Shortly after this he left England, and in 1904 was appointed marine biologist to the Government of Ceylon and four years later in the same capacity to the Government of Madras. Here he began a connexion with tropical seas which occupied the greater part of his working life.

In those years his efforts were mainly directed to the practical application of his investigations, and his elucidation of the cause of a decline in the Ceylon pearl oyster fishery, recommending action which brought back a substantial measure of prosperity, is an outstanding example of his achievements in this direction. Later, he made many other attempts at fishery development, among which may be mentioned his plea for the culture of fish in ponds and lagoons. In urging work of this sort, he produced a report on the conditions under which fish are farmed or cultured at Arcachon and Commachio, recommending similar action in India. The time for what we recognize as developmental and operational research was not yet, however, and the will and resources to implement his schemes were not forthcoming in a way that was worthy of his proposals. In addition to the presentation of development schemes and the day-to-day distractions of administration which became his lot when he was promoted to director of fisheries in 1918, he managed to do a considerable amount of descriptiv biology. It is, indeed, a matter for remark that living so far away from the academic contacts tha might have helped him, he dealt with these studie so competently. There is no doubt that, had h remained in England, his contribution to mor fundamental fishery research would have been outstanding.

A rather special aspect of his scientific outlook arose from the application of a fisheries ecology which included men and gear in relation to the fish they pursued. This led him to produce interesting descriptions of fishing boats and gear before he retired from the Madras Government service in the early 'twenties and which culminated in his classic "Water Transport its Origins and Early Development", published only two years before his death. After he left India, he made many visits to British Colonial Dependencie and Mandated Territories, from which emerged a series of short fishery surveys of great value. In 193 he went to live in Hastings, which remained his home for the rest of his life. Here he entered into the scientific life of the town, studying and describing the structure of local fishing boats and giving hi welcome assistance to the Sussex Sea Fisherie Committee.

Hornell was gifted with a power of lucid exposition evident in all his many publications, making them both a pleasure to read and models of style to those who come after him and regret his passing.

R. S. WIMPENNY

WE regret to announce the following deaths:

Sir Wyndham Dunstan, K.C.M.G., F.R.S., directo during 1903–24 of the Imperial Institute, on April 20 aged eighty-seven.

Prof. F. S. Kipping, F.R.S., emeritus professor o chemistry in University College, Nottingham, o April 30, aged eighty-five.

Dr. W. J. Perry, lately reader in anthropology i the University of London, on April 29, aged sixty-one

Sir Robert Robertson, K.B.E., F.R.S., formerly Government chemist, on April 28, aged eighty.

NEWS and VIEWS

Prof. Doris Mackinnon

PROF. DORIS L. MACKINNON, who retires from the chair of zoology at King's College, London, at the end of the present session, has held the post since 1927, when she succeeded Dr. Julian Huxley. She joined the staff of King's in 1919 when the late Prof. A. Dendy was head of the Department, and endeared herself to generations of students by her professional competence and her sympathetic, wise and helpful guidance. Prof. Mackinnon has published many noteworthy papers on her work, which deals almost entirely with parasitic Protozoa (especially flagellates and Sporozoa). During the First World War she joined the team of workers engaged in the diagnosis of amœbic dysentery and intestinal protozoal infections for the War Office and Medical Research Committee (now Council). When she went to London after the War, she soon established a centre of research in protozoology—for years the only zoological (that is, non-medical) centre of the kind in Britain. By her teaching and research and the work of her pupils she has thereby done much to advance the subject and her publications include many solid and permanent contributions to protozoology. As too frequently in academic appointments, the responsibility c administration tends to make inroads on time fo research; but Prof. Mackinnon kept up a constan flow of publication and gave intercollegiate lecture of characteristic lucidity and thoroughness. In paying tribute to her gifts as a teacher, it would no be out of place to mention the admirable series o broadcast talks on natural history given to schools Her services on the University and College Board and Faculties were particularly appreciated, as sh brought to them a breadth of outlook, sound judgment, scrupulous thoroughness and an altruisti approach not invariably observed on such bodies Fortunately her retirement does not mean that sh will cease her zoological work, and her colleagues an friends will still be able to enjoy her urbane an delightful companionship.

Silver Jubilee of the Indian Chemical Society

THE *Journal of the Indian Chemical Society* is now so well known that many will perhaps be surprised to learn that the Society is only twenty-five years old. The silver jubilee was celebrated at the annual meeting held in Allahabad on January 3 last, when messages of congratulations were received from sister societies in other countries, fittingly headed by one from the oldest Chemical Society, that of London, which recently celebrated its centenary. As was natural, many tributes were paid to the first president, the late Sir Prafulla Chandra Ray, to whom more than to anyone else must be given the credit for the development of chemical research in India. Some account of India's contributions to chemical science is given in a jubilee publication which contains photographs of the past presidents and honorary fellows. In the course of his address, the president, Prof. P. Ray, wisely laid particular emphasis on the importance of fundamental scientific research and to the lack of inspiring teachers and investigators in the schools and universities. According to Prof. Ray, the situation in this respect has recently become worse owing to the departure of many university teachers to take up administrative posts in Government departments. This is a danger present not only in India. Prior to delivering his address, the president announced the election of five honorary fellows, among whom we were glad to note the name of Sir Robert Robinson. We feel sure that, when the Society celebrates its golden jubilee, its fellows will look back with pride and thankfulness to those who served it during its first twenty-five years.

Men, Managers and Machines

IN his monograph "Scientific Management" (Monographs on Higher Management, No. 9, Department of Industrial Administration, Manchester Municipal College of Technology; May 1948), Mr. G. Chelioti urges that the essence of management is the art of getting things done through the agency of other human beings, and that management itself is incapable of becoming a science. He regards science as the foundation and the provider of the tools of industry, and the technician as the primary servant of science in industry; but he points out that the technician cannot manage human beings by means of his technology and that the manager dealing with a technical problem becomes a technologist for the time being. In urging this clear separation of the two functions of dealing with human beings and with technical problems or machines, Mr. Chelioti maintains that the undue domination of industry in the nineteenth century by the new element of modern technology, and the failure to regard industry as the servant of humanity and to consider sufficiently the human beings employed, was responsible for the revolt of the human spirit against subordination to the machine which we are still experiencing in spite of a more enlightened managerial outlook. Mr. Chelioti also reminds us that the current attitude of society was at least as much responsible for the revolt as the contemporary employers or managers, and his words should be carefully weighed in the discussion of the question of human relations in industry to-day.

Fungi as Human Pathogens

IT is fortunate that in Great Britain there are relatively few outbreaks of human disease caused by fungi. Such maladies are, however, much more common in the warmer parts of Europe and in the United States, where considerable study has been devoted to the diseases and their causal agents. Results of these investigations are published in the journal *Mycopathologia* (Dr. W. Junk, den Haag, Holland). The subject brings its own problems, particularly in naming and classification, some of which are discussed in a paper by T. Benedek (4, Fasc. 3; Dec. 1948). It is concluded that the dermatophytes cannot well be classified by the usual methods of botanical mycologists, and that it is preferable to retain the four form genera originally suggested by Sabouraud. This retains the tradition of the Fungi Imperfecti, where species are classified merely from the form of their asexual spores until the sexual forms are discovered. Mycologists will also find, in the same number of *Mycopathologia*, useful papers on the yeast flora of grapes, must and wine (R. Ciferri and O. Verona), and of the 'vegetation waters' separated from olive oil (R. Ciferri, O. Verona and F. Luparini). The blastomycetic microflora of fermenting tobacco is described by M. Giovannozzi. An investigation of antibiotic substances against Gram-negative micro-organisms has been made by G. Magni and A. Villa, and G. Magni has studied the biological significance of the pseudomycelium of asporogenous yeasts. W. J. Nickerson and O. F. Jillson also discuss the interaction of pathogenic fungi in culture, with reference to cell division in the dimorphism of pathogenic fungi. Specialist papers on mycopathology also appear; it is in no invidious sense that they are not reviewed here in detail. There are far more general mycologists than mycopathologists in Great Britain; but the former will nevertheless find much of interest in *Mycopathologia*.

Taxonomy of the Fungi

IN the issue for June 1948 of the *Transactions of the British Mycological Society* (31, Parts 3, 4) there are several papers which help to clarify the systemic positions of many fungi. A. A. Pearson and R. W. G. Dennis have reviewed the validity of the 1,870 specific epithets contained in the latest authoritative work on Agarics (Rea's "British Basidiomycetæ"). They have excluded synonyms, names attached to inadequate descriptions, and other variants of doubtful nomenclature, leaving a total of 1,234 species. Boletales have similarly been reduced from 70 to 47. The valid species are listed with short notes (pp. 145–190), and field mycologists should be grateful to the authors for the removal of such an incubus. This clarification has involved a re-examination by R. W. G. Dennis of several little-known agarics from the herbaria of Berkeley, Cooke and Massee; 29 of these are described in relation to the shorter list (pp. 191–209). Special groups of fungi have also been studied. The late T. Petch provides a revised list of British entomogenous fungi (pp. 286–304), including a new species, *Verticillium menisporoides*, found on spiders in Suffolk. Fungi which are associated with lichens have not hitherto been investigated very intensively. W. Watson lists (pp. 305–339) a large number of these, with notes on their characters and distribution. The Society's "List of Common British Plant Diseases" is kept up to date by the publication of emendations. A collection of these, designed to supplement the third edition of the List, appears in the present number of the *Transactions* (pp. 340–342). A new species of *Pyrenophora* from Italian ryegrass is described by

H. F. Dovaston (pp. 249–253). It is *P. Lolii*, and is possibly the perithecial form of *Helminthosporium siccans*. Other new species are described by N. C. Preston (pp. 271–276)—*Myrothecium jollymannii* from dried tobacco leaves in Nyasaland, and *M. striatisporum* from clay soil in New Zealand.

Establishment and Care of Lawns

AMONG the more general matters dealt with in a recent issue of the *Journal of the Board of Greenkeeping Research* (7, No. 24 ; 1948) are papers on the consolidation of lawn surfaces by bitumen, and a useful review of methods of earthworm control on lawns. R. B. Dawson and J. R. Escritt describe the method of stabilizing the surface of lawns by the application of sand and bitumen emulsion immediately after the grass seeds are sown. The treatment can also be applied to established turf. Lawn surfaces were much improved, and the process may be useful for small areas subject to heavy wear. Detrimental effects were not very marked, but the establishment of bent and timothy grasses was reduced. J. R. Escritt and J. H. Arthur review the methods available for earthworm control. Many species of earthworm do not form casts, and therefore are not a nuisance, but only help in aeration and soil mixing. Organic manures generally stimulate earthworm activity, while the presence of a turf 'mat' diminishes the production of unsightly casts. Factors of management and manuring are therefore important. The relative merits of mowrah meal, copper sulphate, potassium permanganate, derris, mercuric chloride, lead arsenate and other control substances are discussed and provide a very useful advisory review of this matter.

Sugar Beet Viruses

THE virus of sugar beet yellows has not hitherto been regarded as seed-borne. Phyllis E. M. Clinch and J. B. Loughnane have shown, however (*Sc. Proc. Dub. Soc.*, 24, No. 27 ; July 29, 1948), that seed of a new family of sugar beet (No. 41), when germinated, gives a considerable percentage of yellowed seedlings. The identity of this yellowing with sugar beet yellows is somewhat by implication ; but the symptoms and physiological effects are similar. The paper also describes two types of yellows disease from commercial sugar beet crops in Eire. Sugar beet yellows is probably the most serious disease of this crop in England. R. Hull and Marion Watson have a useful paper in the *Journal of Agricultural Science* (37, Part 4, 301–310 ; 1948) on the relation of nutrition and variety with severity of yellows. Manurial treatments in general increase the yields of roots and sugar ; but the losses caused by infection unfortunately increase proportionately as the mean yields increase. Fertilizers have little effect in varying the symptoms of the disease. Commercial varieties and some breeders' lines were tested for possible tolerance of the virus ; but no useful indication of this was obtained.

Norwegian Strandflat

IN a paper in the *Geographical Journal* of January on the "Geomorphology of Norway", Prof. K. M. Ström returns to the topic of the strandflat, a topic which has evoked much controversy in past years. He believes that marine abrasion is much in evidence, though corrie glacier abrasion has played its part. The low plain cuts across fjord deeps and corrie lake deeps, and though local glaciers have certainly played a notable part, it is in the main due to marine abrasion. Prof. Ström cites the example of Moskenesöy, which has practically no strandflat on the inner or sheltered side, but has an abrasion platform 8 km. broad on the exposed side. The tendency to stress glacial action in the formation of the strandflat is probably due to the study of the strandflat where it shows a hummocky appearance through an overflow by ice during the last glaciation. The main features of the strandflat seem to have been abraded at successively lower levels since early Miocene times up to late Pliocene ; this has been followed by excavation by glaciers from the inland ice and corrie glacier erosion and, finally, post-glacial marine abrasion in the peripheral areas where changes of level due to isostatic recovery have been least.

Earthquakes during January

FOURTEEN strong earthquakes occurred in various parts of the world during January. The strongest were those on January 23, 24 and 27, with epicentres in the Indian Ocean (about 600 miles south-west of Sumatra), near the Tonga Islands, and in New Britain respectively. Three earthquakes had deeper foci than is normal ; two, having a depth of about 100 km., occurred on January 23 and 24, and the third, depth 600 km., on January 13 with an epicentre south of the Fiji Islands. It may be noted that no earthquake is so far known to have had its focus at a greater depth than 700 km. All the earthquakes during the month occurred in well-known seismic areas, though the one on January 28 in the Atlantic Ocean some 1,100 miles east of Bermuda is not in an area from which earthquakes often occur. Observatory records have been received from the central stations of the United States Coast and Geodetic Survey and from Strasbourg, and from individual observatories at Beograd (Jugoslavia), De Bilt (Holland), Durham, Kew, Strasbourg, Stuttgart and Toledo (Spain).

Mekran (Baluchistan) Earthquake of November 28, 1945

C. G. PENDSE has discussed all available data for the earthquake at Mekran in Baluchistan on November 28, 1945 (*Ind. Met. Dept., Sci. Not.*, 10, No. 125 ; 1948). The epicentre was in the sea off the Mekran coast, and strength 10 on the Rossi–Forel scale was attained in the epicentral area. The instrumental magnitude was about 6·7, and the energy was of the order of 10^{21} ergs. The earthquake was attended by a seismic sea-wave which affected the whole of the Arabian seaboard. At Karwar, about 1,000 miles from the epicentre, the wave flooded the creeks and inlets, and boats anchored in the harbour were cut off from their moorings. There was serious loss of life and property at Pasni, the height of the second wave there being estimated at between 40 and 50 ft. At Karachi four distinct waves were distinguishable, and at Bombay a seismic sea-wave 6½ ft. high was experienced. It has been reported that two rocky oval islets, about three miles apart, appeared about the same time as the earthquake, some 180 miles west-south-west of Karachi. One islet rose about 30 ft. above the water and the other about 100 ft., the former having an area of about 1½ square miles and the latter about a square mile. Earthquakes have occurred in the past in the area off the Mekran coast on February 4, 1938, and January 7, 1940. Earthquakes on land near the point occurred on September 2, 1938, October 29, 1941, July 3, 1942, July 4, 1942, and February 6, 1943. Very strong earthquakes have occurred in the past at Chaman (Baluchistan) on December 20, 1892; at Kachhi (Baluchistan) on October 21, 1909; at Mach (Baluchistan) on August 27, 1931; as well as at Cutch on June 16, 1819, and at Quetta on May 31, 1935.

Southwest Research Institute, Texas

THE Southwest Research Institute, San Antonio, Texas, has approved of the establishment of a division of oceanography and meteorology and a division of petroleum technology in Houston, Texas. The division of oceanography and meteorology will be of particular scientific importance, since oceanographic data on the Gulf of Mexico are particularly scanty. The research in this field will commence with a survey of currents, the shifting topography of the shelf area, and marine life in the Corpus Christi area, and the work will then be extended eastwards. The schooner *Harpoon* has already been earmarked for research in the Gulf. The oceanographic work will be in two phases: first, the project of the Institute, which will be freely published; and second, the fulfilment of private contracts, which will be paid for by the firms concerned on a cost basis. The establishment of the division of petroleum technology in Houston is the result of the widespread activity with regard to petroleum in that area and the fact that the local industries have immediate problems which can well be undertaken by the Southwest Research Institute. The Institute itself is a non-profit, endowed research organisation.

Unesco Fellowship Handbook

THE secretariat of Unesco has prepared a most useful handbook providing details of all available opportunities for trans-national study and organised arrangements made in this field, which should be of real assistance to those wishing to travel out of their own countries for purposes of study. The handbook, which is intended to be the first of a series, constitutes a repository of information on the considerable investments by governments, universities, foundations and charitable institutions in the promotion of international study. Whether these fellowships or awards are designed to assist the reconstruction or development of a particular country, to encourage scientific research, to stimulate artistic exchange or to promote international understanding in general, they represent a striking volume of assistance from many sources to individuals chosen for their capacity to advance the course of learning and to profit from the cultural heritage of countries other than their own. Copies of the handbook, which may be obtained from H.M. Stationery Office, price 5*s*., show that more than ten thousand opportunities for international study are available for the year 1948–49.

Gamma-Emitting Materials for Industry

THE Ministry of Supply has recently announced that radium and radon can now be supplied for use in industrial radiography. Radium is available on hire only, and will remain the property of the Government. It can be hired for periods of not less than six months, and the average time to fulfil an order is two months. Radon is sold outright, and notice of one week is required for an order. Demonstrations of gamma-radiography for industrialists can be seen by appointment at the Ministry's Armament Research Establishment, Woolwich, London, and at the National Physical Laboratory, Teddington, Middlesex. Radium and radon are supplied by the Radiochemical Centre, Amersham, Bucks, and applications for purchase or loan should be addressed to that establishment.

Spectrographic Research Unit of the Medical Research Council

BY arrangement with the London Hospital, the Medical Research Council has established there a Spectrographic Research Unit under the direction of Dr. E. R. Holiday. The primary function of the Unit is to undertake original research work in the field of absorption spectrophotometry as applied to biological problems of medical interest; but advice and assistance will also be given to other branches of the Council's organisation using such methods. The Unit has been based on the spectrographic department originally established by the London Hospital, and during the last five years partly supported by the Council for the purposes which are now being developed.

Education of the Young Worker

A SECOND Conference on the Education of the Young Worker, with a special subject for consideration, "The Entry into Work, Guidance and Initiation", will be held at Manchester College, Oxford, during July 23–29, 1949. Like its predecessor in 1948, it has been arranged under the auspices of the University Department of Education, the director of which is Mr. M. L. Jacks, and aims at bringing together representatives from industry, education, central and local government departments, voluntary organisations and other bodies which are concerned in the education and welfare of young people between the ages of fifteen and twenty who are no longer in full-time education. The Conference will work in commissions; but whereas last year each commission had a special subject to consider, this year the subjects will be the same for all commissions, each of which will report its findings to the whole Conference at plenary sessions. Further information can be obtained from the Director, University Department of Education, 15 Norham Gardens, Oxford.

British Social Hygiene Council: Summer School in Austria

OWING to various difficulties connected with foreign travel, the Summer School on "The Family and the Nation", which the British Social Hygiene Council had arranged to hold at the University, Berne, Switzerland, during August 17–September 1, has now been transferred to Pertisau in the Austrian Tyrol. There will be no change in the lecture programme, which will deal with different aspects of family life, such as marriage problems, nutrition, human heredity, population, the welfare of old people, the problem family, and juvenile delinquency. As in the past, only the first week will be devoted to study, the second week being entirely free for rest and recreation and for excursions to places of beauty and interest in the surrounding countryside. The cost, including travel, hotel accommodation and tuition, will be approximately £34. Further information can be obtained from the Secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Royal Institution

AT the anniversary meeting of the members of the Royal Institution held on May 2, the following officers were elected: *President:* Lord Brabazon of Tara; *Secretary:* Prof. A. O. Rankine; *Treasurer:* Dr. R. E. Slade; *Managers:* Prof. D. Brunt, Major W. H. Cadman, Sir John Craig, Mr. E. R. Davies, Dr. C. H. Desch, Prof. H. Dingle, Dr. P. Dunsheath, Prof. G. I. Finch, Prof. F. L. Hopwood, Dr. E. T. Paris, Prof. H. J. Plenderleith, Sir Harry Railing, Prof. H. R. Robinson, Prof. A. M. Tyndall, Mr. F. Wakeham; *Visitors:* Colonel S. J. M. Auld, Dr. H. E. Cox, Dr. H. J. T. Ellingham, Dr. R. E. Gibbs, Prof. H. Heywood, Mr. A. J. Hughes, Dr. L. H. Lampitt, Mr. R. Le Rossignol, Mr. A. Marshall, Dr. D. C. Martin, Dr. A. C. G. Menzies, Mr. J. W. Ryde, Mr. F. M. Saxelby, Dr. H. Shaw, Dr. O. H. Wansbrough-Jones.

Capper Pass Awards for Metallurgy

THE Capper Pass Awards for 1948, which are recommended by a committee on behalf of the Institution of Mining and Metallurgy and of the Institute of Metals, have been won by the following: Messrs. C. Blazey, L. Broad, W. S. Gummer and D. P. Thompson (Metal Manufacturers, Ltd., Port Kembla, New South Wales, Australia) £50 jointly, for a paper on "The Flow of Metal in Tube Extrusion"; Mr. H. R. Potts (Minas de Rio Tinto) £50, for a paper on "Further Notes on Converter Practice at Rio Tinto"; Messrs. R. C. Trumbull (Pyrites Co., Inc.), W. Hardiek (Pyrites Co., Inc.) and E. G. Lawford (Rio Tinto Co., Ltd.) £50 jointly, for a paper on "Notes on the Treatment of Pyrites Cinders at the Plant of the Pyrites Co., Inc., Wilmington, Delaware". The money for these awards has been given by Messrs. Capper Pass and Son, Ltd., Bristol, and is allotted as follows: £100 each year for one or more awards to authors of papers on some aspect of non-ferrous extraction metallurgy submitted to the Institution of Mining and Metallurgy; and £100 each year for one or more awards to authors of papers submitted to the Institute of Metals and relating to some process or plant used in the fabrication of non-ferrous metals, contributed by persons engaged full-time in industrial practice. All papers relating to these fields and published in 1949 by either of the two Societies will be considered for awards; authors need not be members of either Society and may be resident in any country. Manuscripts should preferably be submitted in duplicate to either the Secretary, Institution of Mining and Metallurgy, Salisbury House, Finsbury Circus, London, E.C.2, or the Secretary, Institute of Metals, 4 Grosvenor Gardens, London, S.W.1, from whom further particulars may be obtained.

Royal Aeronautical Society: Awards

THE Royal Aeronautical Society has announced the award of the following medals and prizes: *British Gold Medal*, for practical achievement in aeronautics, to Mr. S. Camm, director and chief designer, Hawker Aircraft, Ltd., for his outstanding work in the design and development of fighter aircraft; *British Silver Medal*, for practical achievement in aeronautics, to Lieut.-Commander E. M. Brown, for his outstanding achievements in advancing the technique of deck landing; *Royal Aeronautical Society's Bronze Medal* to Capt. R. N. Liptrot, for his work on helicopters; *Wakefield Gold Medal* to Mr. E. S. Calvert, for his work in the development of airport lighting; *George Taylor (of Australia) Gold Medal* to Mr. G. R. Edwards, chief designer, Vickers Armstrongs, Ltd., Weybridge Works, for his paper on "Problems in the Development of a New Aeroplane"; *Edward Busk Memorial Prize* to Mr. W. Stewart, for his paper on the "Flight Testing of Helicopters"; *Herbert Ackroyd Stuart Memorial Prize* to Mr. W. H. Lindsey, for his paper on "Development of the Armstrong Siddeley Mamba Engine"; *Usborne Prize* to Mr. D. R. Maguire, for his paper on "Enemy Jet History"; *R. P. Alston Memorial Prize* to Mr. B. A. G. Mcgowan, for his work in the flight testing of gliders; *Baden-Powell Memorial Prize* to Mr. R. J. Starling, for being the best entrant in the associate fellowship examination.

Announcements

DR. JOHN RAMSBOTTOM, keeper of botany in the British Museum (Natural History), has been awarded a Grande Médaille Isidore Geoffroy Sainte-Hilaire by the Société d'Acclimatation et de Protection de la Nature.

THE Institute of Metals has appointed the following to be honorary corresponding members for their respective countries: *Belgium*, Henri Féron, administrative director, Visseries et Tréfileries Réunis S.A., Haren; *Holland*, Max Hamburger, director, Royal Nederlandsche Lood- en Zinkpletterijen voorheen A.D. Hamburger, Utrecht; *Italy*, Dr. Leno Matteoli, vice-director, Istituto Scientifico Tecnico Ernesto Breda, Sesto S. Giovanni, Milan.

THE Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1, has published as a booklet of sixty pages Appendix III from the "Universities Yearbook" of 1948. This Appendix consists of a list of postgraduate scholarships and grants for advanced study and research tenable at the universities of Great Britain and Ireland during 1948–49, and though the awards for 1949 have for the most part been already made, yet most of the information will be applicable to next year. The classification of contents is by subjects.

THE Italian review *Ulisse* is offering a prize of one million lire (about £450) for the best work of popular science in the fields of physics or chemistry which has been published in the last five years. The prize is open to books published in Italian, French, English, Spanish and German, and three copies of each book entered for the prize should be sent to *Revista Ulisse* (Sezione Premio Europeo Cortina), Corso d'Italia 43, Rome, before June 15. If the winning work is by a non-Italian author, it is hoped to arrange for the book to be translated into Italian and published in Italy.

REFERENCE was made in *Nature* of April 23, p. 618, to the setting up, by the Parliamentary and Scientific Committee, of a sub-committee to investigate the question of payment for scientific and medical teaching staffs at the universities. We are informed that in view of the new circumstances it has been decided not to proceed with this matter.

ERRATUM.—In the announcement in *Nature* of April 23, p. 634, relating to the Busk aeronautical studentship, it should have been indicated that, subject to the permission of the trustees, the student may carry out his research in Great Britain or abroad.

LETTERS TO THE EDITORS

Radioactive Phosphorus in Biochemical Research

It is generally required in radioactive tracer procedure when applied to biochemical problems that the stable and radioactive molecules or ions possess identical configurations. Only when the two isotopic atoms are supplied in the same chemical form can it be assumed that living tissues will absorb them in the proportions applied. In experiments carried out here with phosphorus-32, it was found that this requirement was not satisfied, and since no information is available on the selectivity of the plants to isotopic elements in different chemical forms, our data cannot be interpreted.

A sample of radioactive disodium hydrogen phosphate with a phosphorus-32 activity of 0·1 millicurie, prepared by slow neutron bombardment of $Na_2HP^{31}O_4$ at the Atomic Energy Research Establishment, Harwell, was used. The irradiated salt was applied in aqueous solution to the roots of growing plants. At the end of the investigation, check experiments indicated that less than 50 per cent of the phosphorus-32 was present as orthophosphate. In other words, half the total phosphorus-32 was present in a different chemical form, or forms, from that of the main bulk of $Na_2HP^{31}O_4$. The analytical procedure used to establish the above fact was as follows: the orthophosphate was precipitated as magnesium ammonium phosphate, ignited to magnesium pyrophosphate, weighed to give 'total' phosphorus, and assayed for phosphorus-32 with a Geiger counter. This precipitate gave less than half the number of counts per minute given by the same volume of original radioactive solution evaporated to dryness in a counting dish. Only rigorous oxidation of the radioactive solution with concentrated nitric acid and 60 per cent perchloric acid prior to precipitation ensured the oxidation of all the phosphorus-32 to orthophosphate, and resulted in a pyrophosphate count comparable with that given by the evaporated aliquot.

Our attention was directed by the Atomic Energy Research Establishment to the work of Libby[1] in which effects of slow neutron bombardment on some inorganic compounds, including those of phosphorus, had been investigated. Libby confirmed that any molecule containing an atom absorbing a neutron would probably be decomposed by the initial recoil of the nucleus, resulting from the emission of the gamma quantum ($P^{31}_{15} + n^1_0 = P^{32} + \gamma$), in a general Szilard–Chalmers type of reaction[2]. In the case of orthophosphates, he suggested that this disruption would result in the ejection of oxygen, presumably the fragment containing the phosphorus-32 being in the form of a phosphite. By some process, however, which seemed to operate during irradiation, Libby found that in the final product about 50 per cent of the phosphorus-32 consisted of regenerated $Na_2HP^{32}O_4$ molecules.

In view of the increasing interest in the application of radioactive tracers to biochemical problems, it is desirable that prospective users of phosphorus-32 should be aware of the severe degradation of sodium orthophosphate which occurs during neutron irradiation in the atomic pile. If a material of a definite chemical form is required, it is essential to use phosphorus-32 prepared by pile irradiation of sulphur-32, and even then the identity of the active material should be confirmed before it is used.

Effect of Enzyme Inhibitors on the Genesis of Phage

It is generally agreed that the multiplication of viruses is intimately linked with the metabolism of the host cell[1]. It seemed, therefore, interesting to study the influence of enzyme inhibitors on the development of virus within the host cell. In this connexion we have launched an extensive investigation with regard to the influence of enzyme inhibitors on the growth of the bacterial cell and the development of 'bacterial virus' particles respectively.

For our first experiments we have used a coli-phage system. Tryptose medium cultures of *Escherichia coli*, strain *B*, were infected with suspension of T_2 phage. The following procedure was adopted: after two and a half hours growth the *E. coli* culture was split up into equal parts, which were treated with various inhibitors for one hour. The number of lytic particles used was calculated so as to assure infection of each bacterium by no more than a single phage particle, and plating out was done after 20 minutes incubation. Some details of the method used have already been reported[2].

Some of the substances examined had no effect on host cell or phage (sodium malonate, sodium fluoride 1/5,000–1/10,000); a second group inhibited both elements in the experimental system (penicillin, acriflavine, mapharside, malonic acid in higher con-

Inhibitor	Concentration (m*M*.)	Number of lytic particles (percentage of original inoculum)
Control		2,000–10,000
Hydroquinone	30	58
	15	78
	7·5	84·1
	50	61·9
	5	86
4-6-Dimethoxy-toluquinone	5·5	99·3
	0·55	124

Urethane	300	77·4
Colchicine	0·008	115
	0·004	180
	0·0004	159

centrations); and a third group checked multiplication of phage, but had no obvious influence on the reproduction of *E. coli*, as was shown by controls (hydroquinone, 4-6-dimethoxy-toluquinone, tetramethyl-*p*-phenylene diamine, malonic acid, iodoacetic acid, auramine, sodium cyanide, sodium fluoride, calcium chloride, urethane, colchicine).

The influence of different concentrations of the substances belonging to this third group upon the multiplication of phage is summarized in the accompanying table.

The substances under consideration belong to different chemical groups, and their range of enzymatic inhibition is varied; but all seem to share one property, namely, that of interfering with succinic dehydrogenase. The influence of succinic dehydrogenase on the multiplication of viruses awaits explanation.

Suppression of the multiplication of phage is shown clearly by the figures in the table; but it seems to be merely temporary, since preliminary experiments with hydroquinone indicate the probability of phage increase at later stages.

Difference between Morphine and Synthetic Analgesics in their Actions on Ganglionic Transmission

THE analgesic actions of certain new synthetic compounds, including pethidine and amidone, have been extensively compared with that of morphine[1]. It is assumed that this analgesic action is mainly due to a central effect, although the possible local anæsthetic properties of these compounds have not been investigated.

Pethidine and amidone, in common with morphine, inhibit both pseudo- and true cholinesterases[2]. There is no evidence to show that their anticholinesterase activity is related to their analgesic properties. But in view of the importance of acetylcholine in the mediation of impulses over autonomic pathways, it is of interest to determine how transmission through autonomic ganglia may be influenced by these drugs.

A structure in which such transmission can conveniently be examined is the cat's superior cervical ganglion perfused according to Kibjakow[3]. In our experiments, we studied the effects of morphine sulphate, pethidine hydrochloride, *l*- and *d-l*-amidone hydrochloride on normal and denervated ganglia, using the nictitating membrane as the indicator of transmitted nerve impulses.

None of these drugs when injected into the ganglion was able to excite a contraction of the muscle; but pethidine and amidone (*l*- and *d-l*-forms) depressed or abolished responses of the nictitating membrane to (1) electrical stimulation of the preganglionic nerve fibres, (2) injection of acetylcholine, and (3) injection of potassium chloride. The depressant effect of each drug was maximal $\frac{1}{2}$–1 min. after injection; with small doses it wore off after 3–20 min.; while with larger doses it might be irreversible. In the case of pethidine, the effective dosage was 10–100 μgm., for *d-l*-amidone it was 5–50 μgm. and for *l*-amidone 1–10 μgm. Thus *l*-amidone was about twice as active as *d-l*-amidone and ten times as active as pethidine. Analogous results were obtained on denervated ganglia when acetylcholine or potassium chloride was used as stimulus.

The action of morphine is entirely dissimilar. In the normal ganglion, even doses so large as 2 mgm. do not alter the response to the above-mentioned stimuli; but in the denervated ganglion, doses of 100 μgm. and upwards have a very marked potentiating action for both acetylcholine and potassium chloride. In the increase of the size of contraction of the muscle, the effect was comparable to that obtained with eserine sulphate (2 μgm.), although it did not last so long.

In further experiments on anæsthetized cats, we have tested the effect of intravenous and intracarotid injections of *l*-amidone; we find that to depress the nictitating membrane response to preganglionic stimulation, the doses then required are 50–100 times greater than those used in the experiments on perfused ganglia. Since the addition of amidone to the general circulation does not diminish the nictitating membrane response to intravenous adrenaline, it seems probable that its depressant effect under both conditions of experiment is due to an action on ganglionic transmission.

In addition, tests carried out on the isolated frog rectus abdominis muscle have shown that its responses to acetylcholine are characteristically modified by pethidine, amidone and morphine: pethidine (minimal concentration 0·0001 M) and *l*-amidone (minimal concentration 0·00001 M) are depressant, whereas morphine (minimal concentration 0·001 M) produces a potentiation.

Concerning these observations, the following comments may be made.

(1) It would appear that the effect, if any, of the anticholinesterase activity on transmission in the autonomic nervous system of pethidine and amidone is overshadowed by their predominantly depressant action. In this connexion, it may be noted that pethidine (5–10 mgm./kgm. intravenously) decreases the irritability of the vagus nerve of the dog[4].

(2) In view of their depressant effects on synaptic transmission, an action which may not be confined to the autonomic nervous system, pethidine and amidone appear to be potentially more dangerous than morphine, which does not share this property.

(3) The quantitative differences between the activities of pethidine, *d-l*-amidone and *l*-amidone in depressing ganglionic transmission correspond approximately with the differences in their effectiveness as analgesic agents. In both cases pethidine is the least powerful, whereas *l*-amidone is the most powerful, and *d-l*-amidone is intermediate between the other two.

(4) The analogous behaviour of the frog rectus muscle and of the superior cervical ganglion in their susceptibility to the depressant effects of pethidine and amidone, and to the potentiating action of

morphine, is a further indication that the ganglion cell with its axon has many properties in common with the motor end-plate and its muscle fibre.

Sympathin

MANY workers are now engaged in studies on the substance or substances liberated at the nerve endings when sympathetic nerve fibres are stimulated. In some cases, it has been shown to be adrenaline, whereas in others results indicate that it may be *nor*adrenaline. Recently, Bülbring and Burn[1] showed that even splanchnic nerve stimulation (after evisceration and ligation of the renal vessels in spinal cats) can result in the liberation of varying proportions of *lævo-nor*-adrenaline with the adrenaline.

In cats under chloralose and cocaine, after double vagotomy, we have been able to show that in at least two cases the nature of sympathin (as shown by effects produced in distant parts of the animal) depends upon the length of time the nerve has been sectioned before being stimulated. Stimulation of the hepatic nerve immediately after sectioning, for example, produced contraction of the denervated nictitating membrane, relaxation of the non-pregnant uterus and a rise of blood pressure, effects well equated by slow intraportal infusions of equi-pressor doses of adrenaline (not *nor*adrenaline). Two hours or more later, stimulation produced contraction of the nictitating membrane and a smaller rise of blood pressure but no action on the uterus, effects well equated by slow intraportal infusions of equi-pressor doses of *nor*adrenaline (not adrenaline). A very small stimulus to the splanchnic nerve applied immediately after, and several hours after, sectioning produced similar results, although the matching was carried out, in this case, by slow intravenous infusions of equi-pressor doses of adrenaline or *nor*-adrenaline. Hypogastric nerve stimulation did not, however, give corresponding results, for the sympathin effects as recorded by relaxation of the non-pregnant uterus were always equated by slow intra-arterial infusions of adrenaline.

After dibenamine (15 mgm./kgm.), stimulation of the hepatic nerve immediately following sectioning produced slight relaxation of the non-pregnant uterus, and a fall of blood pressure preceded by a small rise. The rise could be produced by sham stimulation and was probably due to constriction of the hepatic artery. The fall was well equated by slow intraportal infusions of adrenaline. Later, stimulation produced no effect on the uterus, and a rise of blood pressure only, corresponding to the action of slow intraportal infusions of *nor*adrenaline. Similar effects, however, could not be produced by normal adrenaline-reversal doses of ergotoxine.

It appears, therefore, that sectioning of some sympathetic nerves may be linked with the inhibition of methylation of the primary amine, so that stimulation produces more *nor*adrenaline and less adrenaline. In these cases, the normal adrenergic mediator may be a mixture of varying proportions of adrenaline and *nor*adrenaline.

It is hoped to analyse the blood at various stages and so identify the substance or substances liberated.

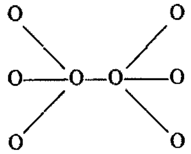
Phloroglucitol Diammoniacate, $C_6H_9(OH)_3.2NH_3$

THE determination of the crystal structure of phloroglucitol dihydrate, besides establishing the fact that the α-phloroglucitol molecule has the configuration κ,κ,κ, shows that the water molecules are chiefly responsible for the cohesion of the organic molecules in the lattice[1]. The structure is rhombohedral, and in the (111) planes equilateral triangles of hydroxylic oxygens are formed, each of the three oxygen atoms belonging to a separate phloroglucitol molecule. On the line perpendicular to the plane of the triangles and joining the centres of two triangles, *two* water molecules are situated; and the distance from each water oxygen to the nearest three alcoholic oxygens and also the distance between the two water oxygen atoms is about 2·75 A. It is obvious, therefore, that the bonds linking together the



group are hydrogen bonds.

We thought it possible that a structure based on this arrangement might be preserved, at least at low temperatures, when the two water molecules are replaced by molecules of ammonia. Anhydrous phloroglucitol was therefore dissolved in liquid ammonia free from traces of water, and the ammonia allowed to evaporate slowly. The crystals formed in this way showed a development very similar to that of the dihydrate. They are quite stable when kept in a closed vessel at 0° C., but at room temperature and in the open air the ammonia escapes, leaving a powder of anhydrous α-phloroglucitol.

Taking special precautions it was possible, however, to obtain X-ray photographs of single crystals and to ascertain that the crystal structure corresponds to that of the dihydrate mentioned above. The lattice dimensions are, however, a little greater than those of the dihydrate. This is just what would be expected, because both the O—H—N and N—H—N bond distances must be somewhat larger than the corresponding O—H—O distances. The intensities of corresponding X-ray reflexions, although not identical, are very similar.

It seems reasonable to believe that the possibility of replacing water by ammonia is not limited to the hydrate of the trivalent alcohol in question, and it seems even possible that other substances than ammonia capable of forming hydrogen bonds may build up structures corresponding to those of the hydrates. Further studies in this direction, now in preparation, may give valuable information concerning the properties of hydrogen bonds. Full details concerning the structure of the phloroglucitol diammoniacate will be published in *Acta Chemica Scandinavica*.

Structure of Polyglycine

In a preliminary report on a chemical, X-ray and infra-red investigation of synthetic polypeptides[1], one of the forms of polyglycine was tentatively assigned a rectangular unit cell of dimensions: $a = 4\cdot36$ A. (or twice that), $b \approx 7$ A., and $c = 3\cdot44$ A. I should like now to correct this in the light of more recent considerations.

At a meeting in November 1948 of the X-Ray Analysis Group of the Institute of Physics, it was suggested by Bunn that polypeptides with shorter side-chains, and polyglycine in particular, might be expected to fit together in approximate close-packed arrangements like that found in the polyamides (nylons)[2], in which, though the interplane *spacing* is $4\cdot36_5$ A., the actual distance between chains bridged by CO . . . NH hydrogen bonds is 4·77 A. Rudall, working in this laboratory, and reviewing in another connexion the types of packing in protein structures, has also lately directed my attention to the improbably high density (about 1·8 gm./c.c.) that would be required if polyglycine had the rectangular cell proposed. We had no density data at the time; but the density of a preparation of polyglycine film has now been measured[3] and found to be close to 1·51 gm./c.c.

Taking Bunn's scheme and the same hydrogen-bonded distance between chains as in nylon, together with the residue-length (3·67 A.) estimated by Corey[4] for a completely extended polypeptide, the calculated density of polyglycine is

$$\frac{57 \times 1\cdot65}{4\cdot77 \times 3\cdot44 \times 3\cdot67} = 1\cdot56 \text{ gm./c.c.},$$

in satisfactory agreement with experiment. On this basis the β-angle is $\sin^{-1} 4\cdot36/4\cdot77 = 66°$; also, of course, practically the same as the corresponding angle in nylon.

The special importance of this result is in relation to the infra-red data[1], which show that in spite of substantial variations in backbone spacing, the CO . . . NH linkage remains virtually unchanged. Bunn's interpretation would be to keep a fairly constant inter-chain backbone distance (round about 4·77 A.) and let the β-angle increase with increasing side-chain distance until in β-keratin, for example, where the backbone spacing is 4·65 A., the cell becomes approximately rectangular (as direct observation shows[5]); and there seems little doubt now that this view is sound as regards polyglycine at least. Whether it is generally valid for polypeptides with longer side-chains—and there are evident difficulties at the moment—must await the results of calculations from density data not yet available.

Refining of Oils Containing Vitamin A

THE alkali-refining of fish liver oils containing vitamin A has, in the last few years, acquired increased importance due to the development of molecular distillation. This method of distilling, while yielding concentrates of a high vitamin A content, requires, in order to obtain satisfactory results, oils free from impurities and with low acid-values. Alkali-refining provides the best means of satisfying this requirement; but it has been considered that a treatment of this kind decreases the potency of vitaminic oils because of the adsorption of vitamin A by soaps formed *in situ*[1].

Experiments carried out in this Laboratory with a number of fish liver oils seem to indicate that under normal refining conditions just the opposite is the case. The neutralized oil, far from losing anything of its original potency, extracts to a large extent vitamin A from the soap formed during the neutralization, so that the result of the alkali-treatment is increased, and not diminished, potency. In oils with high potency and high acid-value, this increase can be quite substantial, as illustrated by the following example.

A sample of Groper liver oil with 120,000 I.U. of vitamin A per gm., 12·5 per cent free fatty acids and 3·95 per cent impurities[2] was neutralized with an excess of sodium carbonate, centrifuged and filtered. The results are shown below:

	Weight (gm.)	Vitamin A potency (I.U. per gm.)	Total content of vitamin A (I.U.)
Original oil	24·50	120,000	2,940,000
Neutralized oil	18·75	140,000	2,625,000
Oil in soapstock	5·75 (by difference)	44,000	253,000

The 5·75 gm. of soapstock oil consisted, according to the analysis, of 3·06 gm. fatty acids, 0·97 gm. impurities and 1·72 gm. neutral oil, which latter could be extracted with petrol ether from the soapstock. The potency of this oil can be assumed as 140,000 I.U. per gm., the same as the bulk of the neutralized oil, and consequently 1·72 gm. of it accounts for 240,800 I.U. out of the total of 253,000 I.U. in the soapstock. This leaves for the fatty acids in the form of soap, and for the impurities, 12,200 I.U., or less than 0·5 per cent of the total amount of vitamin A present in the original sample.

The loss of vitamin A during the alkali-refining is, therefore, due mainly to some neutral oil being carried away with the soapstock, while the potency of the neutralized oil has increased. As the latest refining methods allow of a loss closely approaching the theoretical Wesson loss, the amount of trapped neutral oil being reduced to a minimum, it seems now beyond doubt that alkali-refining provides the most economical and simple method of purifying oils containing vitamin A.

It may be added that the alkali-refining of vitaminic oils prior to molecular distillation is covered by a patent[3]. In the example contained in this patent, there is an indication of increased potency of neutralized oils, inasmuch as 4,600 gm. of pollack liver oil having a vitamin A potency of 10,600 units per gm. (or a total of 48,760,000 units) has yielded 4,285 gm. of refined oil with a vitamin A potency of 12,200 units per gm. (or a total of 52,277,000 units). This increase, however, shown without any explanation, amounts to a net gain of 3,517,000 units of vitamin A produced out of nothing, and, therefore, must be attributed to an experimental error.

Explosive Decomposition of Ethylene Oxide

THE slow decomposition of ethylene oxide vapour has received the attention of a number of investigators[1-3]. In extension of their work, we have studied the limiting conditions of temperature and pressure under which the reaction becomes explosive in a 550 c.c. quartz bulb.

At 773° K., the presence of nitrogen very slightly raises the minimum ignition pressure, as the following figures show:

Moles N_2 added per mole C_2H_4O	Pressure (partial) C_2H_4O at limit (mm.)
0	90
0·5	91
1·0	93

This result suggests that the ignition is of a thermal character and that, in accordance with the weight of opinion regarding the slow decomposition, the reactions leading to ignition do not involve chains. For such a thermal ignition the pressure (p) and temperature (T) at the ignition limit are related, theoretically, by $\log_{10} p/T = A/T + B$, where A and B are functions of the thermal properties of the system and the kinetics of the reaction leading to ignition.

We have traced the p–T explosion limit of ethylene oxide from 90 mm. at 773° K. to 325 mm. at 743° K., and find that between these points the graph of $\log p/T$ against $1/T$ indicates a continual decrease of A and/or B with rising temperature. The most probable explanation is that B is decreasing, thus implying an increase in the order of reaction with increasing temperature, that is, with decreasing pressure. This conclusion is in accordance with the findings of Thompson and Meissner[2] with regard to the slow decomposition reaction in the same pressure-range.

Our detailed conclusions on this subject, together with those relating to the flame reactions of ethylene oxide in the presence of oxygen[4], will be published in due course.

Stability of Chelate Complexes

ATTENTION has recently been directed to parallelisms in the order of the stability constants of the complexes formed by bivalent metal ions with different ligands[1,2]. We have investigated the stability constants of the complexes formed by metal ions with β,β′,β″-triaminotriethylamine, $N(CH_2CH_2NH_2)_3$, (tren), which can provide four ligand atoms for a given ion, as previously shown by Mann and Pope[3], who prepared complexes of this tetramine with several bivalent ions. The stability constants have been evaluated by combining the acidity constants of the acid $(trenH_3)^{3+}$ with the equilibrium constants of the reaction:

$$M^{2+} + (\text{trenH}_3)^{3+} \rightleftharpoons M(\text{tren})^{2+} + 3\text{H}^+.$$

Measurements were made at 20° C. with a hydrogen or glass electrode at an ionic strength of 0·1 (usually a 0·1 *M* solution of potassium chloride was used and a correction for chloro-complex formation applied where necessary). Except in the cases of silver and mercury, and to a much lesser extent nickel, intermediate steps do not occur in the neutralization of the acid in the presence of a complex-forming ion, the three protons being ejected together. This greatly simplifies the interpretation of the data. Furthermore, at the concentrations used (10^{-3} *M*) there was no indication of the formation of polynuclear complexes. The logarithms of the apparent stability constants

$$\left(k = \frac{[M(\text{tren})^{2+}]}{[M^{2+}]\,.\,[\text{tren}]}\right)$$

are as follows (their dependence on ionic strength should be small since the ligand is a neutral molecule):

M	Mn	Fe	Co	Ni	Cu	Zn	Cd	Hg
log*k*	5·8	8·6	12·8	14·6	18·8	14·6	12·3	~ 22·8

The order of the constants is in general the same as that observed with ammonia, ethylene diamine(en) and in other cases, in spite of the fact that a planar configuration is sterically impossible for the four nitrogen atoms surrounding the metal atom, which might be expected to lead to a decrease in the relative stability of the copper and nickel complexes.

	Mn	Fe	Co	Ni	Cu	Zn	Cd	Hg

The loss of entropy on formation of a complex ion will be less when two or more ligand atoms are present in the same complex partner, but a comparison between the corresponding stability constants for ammonia, ethylenediamine[4] and β,β′,β″-triaminotriethylamine indicates that other factors, probably of a steric nature, are also of importance. It will be seen that the change in complex ion stability due to chelation varies considerably with the metal involved. The copper complex with β,β′,β″-triaminotriethylamine is actually less stable than that with ethylenediamine; an examination of the differences in the logarithms of the sets of stability constants given above indicates in the case of the ethylenediamine complexes a comparatively high stability of the copper and nickel complexes, and a low stability of the zinc and cadmium complexes. This is probably due to the tendency of copper and nickel to form complexes with a square configuration of the ligand atoms, whereas with zinc and cadmium the configuration is usually tetrahedral. In an ethylenediamine complex with a large central atom, the tetrahedral arrangement of amino groups will involve considerable strain in the two five-membered rings[5].

As in some other instances, the logarithms of the stability constants for β,β′,β″-triaminotriethylamine increase approximately linearly with the sum of the first two ionization potentials of the gaseous metal atoms, presumably indicating an underlying similarity between the electron energy-levels in the complex ions and in the corresponding metal atoms.

Details of our measurements with this and other 'complexons' will be published elsewhere.

Formation and Decomposition of Ferrous αα′-Dipyridyl

A recent note in this journal[1] on the reaction between ferrous ion and αα′-dipyridyl (Dipy) induces us to report briefly on our investigations of this reaction. In a general way, our experimental results confirm the findings of Baxendale and George; they reveal, however, some new aspects of this reaction.

The decomposition of $\text{FeDipy}_3{}^{2+}$ in acid (HCl) solution may be represented at $[\text{H}^+] < 5 \times 10^{-2}$ fairly well by the equation

$$-\frac{d}{dt}[\text{FeDipy}_3{}^{2+}] = \{k_{d_0} + k_{d_1}[\text{H}^+]\}\,[\text{FeDipy}_3{}^{2+}];$$

indicating that beyond the monomolecular decomposition of $\text{FeDipy}_3{}^{2+}$, there is a reaction involving hydrogen ions. As the value of k_{d_1} decreases sensibly at higher hydrogen ion concentrations, it may be supposed that the rate-determining step is the monomolecular decomposition of an intermediate, $\text{FeDipy}_3\text{H}^{3+}$, rather than a bimolecular reaction between $\text{FeDipy}_3{}^{2+}$ and H^+. On this assumption the kinetics may be represented correctly up to *p*H 0 by the equation

$$-\frac{d}{dt}[\text{FeDipy}_3{}^{2+}] = k_{d_0}\,[\text{FeDipy}_3{}^{2+}] + k_{d_2}\,[\text{FeDipy}_3\text{H}^{3+}] =$$
$$\left\{k_{d_0}\left(1 - \frac{[\text{H}^+]}{[\text{H}^+] + K_3}\right) + k_{d_2}\frac{[\text{H}^+]}{[\text{H}^+] + K_3}\right\}[\text{FeDipy}_3{}^{2+}]_{\text{total}}.$$

The values of the constants at 25° and $\mu = 0{\cdot}33$ are $k_{d_0} = 7{\cdot}45 \times 10^{-3}$ min.$^{-1}$, $k_{d_2} = 8 \times 10^{-2}$ min.$^{-1}$ and the dissociation constant of $\text{FeDipy}_3\text{H}^{3+}$, $K_3 = 0{\cdot}6$. At $\mu = 0{\cdot}01$ the value of k_{d_0} decreases by about 10 per cent. The values of the activation energies are 29·5 kcal. for the reaction independent of hydrogen ion concentration and about 26 kcal. for that dependent on it, K_3 showing little or no dependence on temperature.

The formation of $\text{FeDipy}_3{}^{2+}$ from Fe^{2+} and HDipy^+ (αα′-dipyridyl HCl) at $[\text{H}^+] < 6 \times 10^{-2}$ follows approximately the equation

$$\frac{\Delta}{\Delta t_0}[\text{FeDipy}_3{}^{2+}] =$$
$$k_{f_0}[\text{Fe}^{2+}][\text{Dipy}]^3 + k_{f_1}[\text{Fe}^{2+}][\text{Dipy}]^2[\text{HDipy}^+] =$$
$$\left\{k_{f_0} + \frac{k_{f_1}}{K_a}[\text{H}^+]\right\}[\text{Fe}^{2+}][\text{HDipy}^+]^3\left(\frac{K_a}{K_a + [\text{H}^+]}\right)^3$$

(where $\Delta/\Delta t_0$ represents the initial velocity) if $[Fe^{2+}]$ is small in relation to $[HDipy^+]$. At higher concentrations of ferrous ions, an increase of these is not accompanied, however, by a proportional increase in velocity; on the contrary, after having reached a maximum value, the velocity decreases with a further increase of concentration of ferrous ions. Assuming that this behaviour is due to a rapid formation of an intermediate $FeDipy^{2+}$ which reduces the available concentrations of Fe^{2+} and $HDipy^+$ (and increases the concentration of hydrogen ions), it is possible to represent the kinetics within the experimental error of ± 10 per cent over a wide range of concentrations, especially with regard to the peculiar dependence on the concentration of ferrous ions, as shown in the table.

$[Fe^{2+}]$	1·37	5·5	55	165	555 × 10^{-5}
v_0 found	18·5	69	355	285	105 × 10^{-7} min.$^{-1}$
v_0 calcul.	18·7	68	331	310	107 × 10^{-7} min.$^{-1}$

$[HD^+] = 1{\cdot}66 \times 10^{-4}$, $[H^+] = 1{\cdot}60 \times 10^{-3}$, $T = 25°$, $\mu = 0{\cdot}33$

The values of the constants at 25° and $\mu = 0{\cdot}33$ are $k_{f_0} = 2{\cdot}7 \times 10^{15}$ min.$^{-1}$ and $k_{f_1} = 1{\cdot}75 \times 10^{12}$ min.$^{-1}$, using the values $K_a = 3{\cdot}7 \times 10^{-5}$ for the dissociation constant of $HDipy^+$ and $K_{FeDipy} = 2{\cdot}7 \times 10^4$ for the equilibrium constant of $FeDipy^{2+}$. At $\mu = 0{\cdot}01$ and $K_a = 4{\cdot}65 \times 10^{-5}$, K_{f_0} is about $1{\cdot}7 \times 10^{15}$.

If $FeDipy_2{}^{2+}$ is assumed to be the sole stationary intermediate, it is not possible to represent the kinetics in a satisfactory manner. It is, however, possible to regard $FeDipy_2{}^{2+}$ as second intermediate, but only if its stationary concentration is small in comparison with the concentration of $FeDipy^{2+}$. This assumption is even probable on account of the form of the second term of the velocity equation.

The final, rate-determining steps would then be

$$FeDipy_2{}^{2+} + Dipy \rightarrow FeDipy_3{}^{2+}$$
$$\text{and } FeDipy_2{}^{2+} + HDipy^+ \rightarrow FeDipy_3H^{3+}.$$

The overall velocity constant is, within the experimental error, independent of the temperature, K_{FeDipy} showing a small negative temperature coefficient.

The equilibrium constant

$$K = \frac{[FeDipy_3{}^{2+}]}{[Fe^{2+}]\,[Dipy]^3} = \frac{[FeDipy_3{}^{2+}]}{[Fe^{2+}]\,[HDipy^+]^3} \cdot \left(\frac{[H^+] + K_a}{K_a}\right)^3$$

is fairly constant only if $[Fe^{2+}] < [HDipy^+]$. With a correction, however, for the formation of $FeDipy^{2+}$, using the kinetic value of $K_{FeDipy} = 2{\cdot}7 \times 10^4$, K remains constant over a very wide range of concentrations, even when the uncorrected value is so low as $K/100$.

The average value of the equilibrium constant at 25° and $\mu = 0{\cdot}33$ is $K = 3{\cdot}8 \times 10^{17}$, decreasing to about $2{\cdot}5 \times 10^{17}$ at $\mu = 0{\cdot}01$. The kinetic value of K calculated as the coefficient of the velocity constants of the opposed reactions is $3{\cdot}6 \times 10^{17}$, in excellent numerical agreement with the value directly found.

The heat of formation of $FeDipy_3{}^{2+}$ at 25° is about 28 kcal. Thus the velocity constant k_{f_0} should have a small positive temperature coefficient (of less than 10 per cent per degree).

We shall try to find further confirmation of the existence of intermediates by investigating the kinetics in neutral solutions and by other methods. A full account of this work will be published elsewhere.

P. Krumholz

Research Laboratory of Orquima, S.A.,
São Paulo.
Jan. 6.

Baxendale, J. H., and George, P., *Nature*, **162**, 777 (1948); see also Kolthoff, I. M., Lee, T. S., and Leusing, D. L., *Anal. Chem.*, **20**, 985 (1948), on the analogous reaction with *o*-phenanthroline.

The value of K_{FeDipy} obtained by Dr. Krumholz from kinetic measurements agrees very well with a value of $1{\cdot}64 \times 10^4$ (independent of temperature) which we have obtained from equilibrium measurements based on the incomplete formation of $Fe(Dipy)_3{}^{2+}$ in excess ferrous ion reported earlier. It appears from our results that it is not possible to obtain appreciable amounts of $Fe(Dipy)_2{}^{2+}$; hence a precise value of K_{FeDipy_2} cannot be obtained, but only its upper limit, $K_{FeDipy_2} \ngtr 10^5$.

Over the *p*H range 0–2·5, our results on the dissociation of $Fe(Dipy)_3{}^{2+}$, in hydrochloric acid solution agree with those of Dr. Krumholz, although we believe that the simple explanation involving the formation of the intermediate $Fe(Dipy)_3H^{3+}$ is insufficient to explain the following observations. First, the first-order dissociation-rate constants at 35° C. depend on the acid used, and the differences cannot be accounted for by the differing hydrogen ion activities. Secondly, above 1·0 *N* hydrochloric acid, the rate constants are far below the predicted values based on $Fe(Dipy)_3H^{3+}$ formation. For example, at 25° and 35° C., the maximum first-order constants at high hydrogen ion concentration on this assumption (k_{Dipy_2}) are $8{\cdot}0 \times 10^{-2}$ and $33{\cdot}4 \times 10^{-2}$ min.$^{-1}$, whereas our observed values are $4{\cdot}4 \times 10^{-2}$ and $21{\cdot}6 \times 10^{-2}$ min.$^{-1}$ independent of the acid concentration. Experiments on dissociation in the presence of high salt concentrations at about 0·2 *N* acid show the rate constants to be little altered, so these effects cannot be attributed to kinetic salt effects.

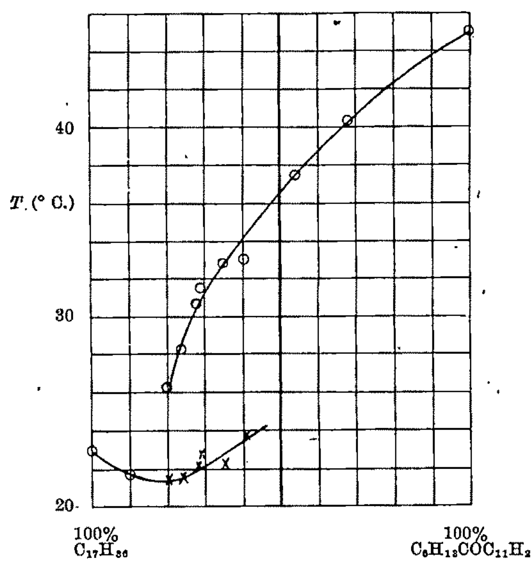
A Co-operative Transition in a Mixed Ketone Shown by a Change of Dielectric Constant

In a paper on the dielectric properties of dipolar solids, Fröhlich[1] considers the theory of second-order transitions in long-chain ketones. Starting from the crystal structure of these materials, he shows the possibility of co-operative transitions in the solid, and derives an expression for the behaviour of the dielectric constant at such a transition. This theory is derived for pure ketones; but so far no ketone has been found to show a transition of the type in question, the energy conditions being apparently unfavourable. However, such a transition has now been found in a binary mixture of a ketone and a paraffin, namely, 25 per cent of $C_6H_{13}COC_{11}H_{23}$ with 75 per cent of $C_{17}H_{36}$.

The mixture in question has two phases when in equilibrium, the main component being a solid solu-



o—o—, Stable melting points; ×—×—, metastable melting points

Fig. 1. Melting points of mixtures of $C_6H_{13}COC_{11}H_{23}$ and $C_{17}H_{36}$

tion of 10–20 per cent of ketone in paraffin, and the other predominantly the ketone. However, equilibrium is reached only after prolonged annealing, and the mixture can be quenched as a metastable homogeneous solid solution of ketone in paraffin. The physico-chemical properties of the mixture follow most clearly from the melting point diagram of the binary system $C_6H_{13}COC_{11}H_{23} + C_{17}H_{36}$ (see Fig. 1).

The dielectric constant of the mixture of 25 per cent ketone and 75 per cent paraffin was measured at two frequencies, 3 × 10^6 and 1 × 10^3 cycles/sec. A capacitor was used which allowed rapid quenching of the specimen. Fig. 2 shows a typical curve, obtained, in the case shown, on a quenched specimen at 3 × 10^6 cycles/sec. The results are independent of frequency, within the limits of error. It may be seen that within a considerable temperature interval below the melting point the dielectric constant behaves as in the liquid; the discontinuity at 22° C., the metastable melting point, appears to be due to volume changes and macroscopic orientation effects. The drop of the dielectric constant at about 4° C., which is independent of frequency, indicates a chan of structure from one with mobile dipoles to o with immobile dipoles, the changes being gradu over a temperature interval. The values measur for the annealed, two-phase form are not material different from those shown in Fig. 2 for the met stable form, since the main component of the mixtu is still a solid solution of the ketone in paraffin.

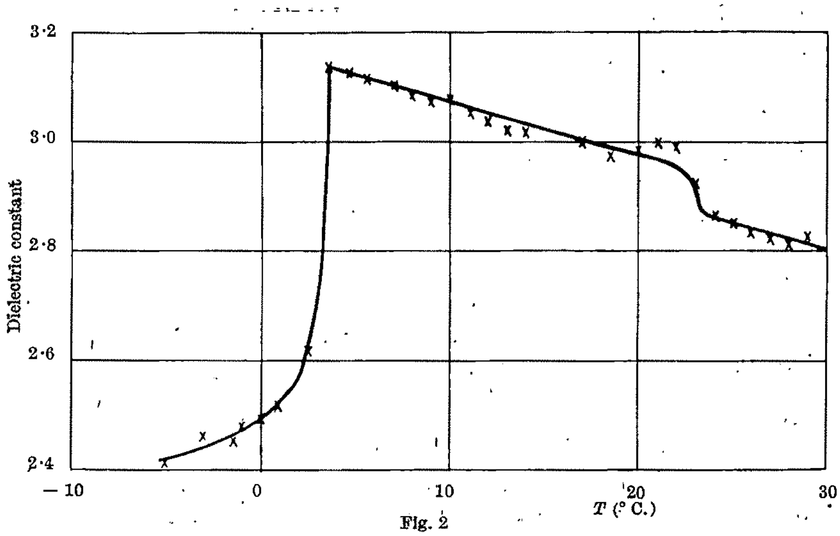


Fig. 2

The measurements in question are only preliminar The necessity of quenching the specimen involved reduction in the precision of measurement of bo the dielectric constant and temperature. It is hop to repeat them more exactly. However, they sho clearly the existence of a co-operative transiti analogous to that predicted by Fröhlich.

The existence of second-order transitions in paraffi is, of course, well known through the work of Mülle Ubbelohde[3] and others. The novelty of the prese result consists in the fact that the transition fou lies far below the melting point and that it can followed by means of the dielectric constant, so th a theoretical treatment on the lines suggested Fröhlich may be possible.

Water Layers in Vermiculite

GRUNER[1] has shown that vermiculite consists talc-like layers, 9·26 A. high, alternating with wat layers (4·95 A.), the total water content of t mineral being in the region of 20 per cent. Theories[2] as to the nature of the water layers have found dif culty in explaining the observation[1,2,3] that, wh vermiculite is heated at 110° C., about half the wat is removed without apparently affecting the di fraction pattern. It can be shown, however, that change in the structure does, in fact, take place duri this treatment; but that the rapid rehydration whi occurs on contact with normal atmospheric conditio tends to obscure it. Thu while the diffraction patter of unheated and rehydrat samples are identical, a po der specimen heated at 110° and sealed in a thin gla tube before rehydration c occur does not give t usual 14·2 A. basal reflexi of vermiculite but one 11·8 A. corresponding to water-layer thickness of 2· A., which is about half t original value. A sing flake similarly treated sho the 11·8 A. reflexion to associated with a regul sequence of higher order that is to say, it represen a real spacing and is n a diffraction effect from i timately mixed layers of di ferent sizes[4]. It is clear, therefore, that removal of half the water is accompanied by replacement of an original double water-layer by a single layer.

The reason for the rapid and spontaneous rehydration which takes place on contact with atmospheric moisture is not so obvious, but appears to be bound up with the very high cation-exchange capacity of this mineral, which is comparable with that of montmorillonite. Tests made in this laboratory on several vermiculites have shown that the mineral has a maximum exchange capacity in the region of 130 m.equiv. per 100 gm., and that, in natural vermiculite, the exchange positions are always occupied by Mg^{2+} ions, the frequency of occurrence of these ions between the basal-plane surfaces being about 1·17 per unit cell.

In natural magnesium-saturated vermiculite, the height of a water layer is sufficient for each magnesium atom to be surrounded by a single hydration shell of six close-packed water molecules arranged octahedrally. Since the chemical formula[5] of vermiculite requires 16 water molecules per unit cell, there will be approximately 14 water molecules between the basic talc-like layers for each exchangeable magnesium ion and, for each octahedral group of magnesium-shell waters, approximately 8 'extra-shell' water molecules less tightly bound. According to the chemical formula of vermiculite, 30 per cent of the total water consists of hydroxyl groups, so that these 'extra-shell' water molecules would constitute almost half the total water content of the mineral, the half presumably which is released at 110° C.

The evidence suggests that, on removal of these 'extra-shell' molecules, the octahedral groups surrounding the exchangeable magnesium ions spread out over the basal-plane surfaces in a single layer; but that the strong tendency of the magnesium ions to become rehydrated causes reversion to the original structure as soon as extra moisture becomes available. Further, if the exchangeable magnesium ions occurring in natural vermiculite become hydrated in the manner suggested and their calculated frequency is of the right order, an inadequate amount of space would seem to be left for the development on any appreciable scale of Hendricks and Jefferson's[3] hexagonal groups of water molecules.

The theory outlined above requires that the configuration of the water layers in vermiculite should be largely determined by the type of exchangeable ion present, and this is, in fact, found to be so. Thus, replacement of the magnesium ions in exchange positions by monovalent and divalent ions causes changes in the c-dimension of the unit cell, as seen on an X-ray powder photograph; so that after leaching with a potassium salt, for example, the strong 14·2 A. basal reflexion of magnesium-saturated vermiculite is replaced by a diffuse line centred on 11·0 A., while ammonium-saturated material gives a broad line at about 10·6 A. and barium-saturated material a line at 12·3 A.

Sublimation in Outdoor Air and Seeded Sublimation

At intervals over the past twelve months, expansion chamber tests of the threshold temperature for the formation of ice crystals in supersaturated air have been carried out at this College. Of the various weather conditions experienced, it was found that with strong sea winds (N. and S., 5 or more on the Beaufort scale), the threshold value remains constant at − 41·2° C., which is the value found previously for nuclei-free air[1]. In other weather conditions the threshold is variable between − 41·2° C. and − 32·2° C. The latter is the value already found for the ground layer of air in England. Diurnal variations are sometimes as large as 4° C. It appears that there is a whole 'spectrum' of sublimation nuclei in polluted air.

In view of the recent discovery of the seeding properties of silver iodide[2], its tendency to initiate the sublimation of water vapour was tested in an expansion chamber and on the test plates of hoar-frost hygrometers.

(*A*) *Expansion chamber tests.* Samples of chemically pure silver iodide were evaporated from a platinum wire, and expansion chambers were ventilated with air rich in silver iodide micro-crystals. The threshold sublimation temperature was found to be − 2·9° C. (± 0·1° C.). A decrease in the final temperature of a few tenths of a degree centigrade below this critical value practically fills the chambers with ice dust.

(*B*) *Frost point hygrometer tests.* Seeding of the surfaces of frost-point hygrometers with silver iodide micro-crystals was performed by condensing silver iodide (evaporated from a platinum wire) on polished surfaces. In testing various sizes of the crystals, it was found that the most active surface is one which is only just 'sensitized' by silver iodide (in the terminology of molecular beam physicists), that is, when the crystals are invisible. On such a surface, when freshly prepared, sublimation begins at − 2·9° C. (± 0·05° C.). At this critical temperature only a few ice crystals start to grow, and when air, supersaturated in respect to the dew point, was admitted over the surface, supercooled water started to deposit between the crystals, leaving clear areas closely around each crystal. With thimble temperatures above − 2·9° C., only supercooled water deposits on the thimble. When the thimble temperature is only 0·2° C. lower than the critical value, the sublimation activity of the surface is so high that it is impossible to deposit supercooled water even if very moist air is admitted to the hygrometer. The surface is covered at once with a multiplicity of ice crystals, resembling fine emery. The ageing of surfaces seeded with silver iodide proceeds relatively slowly. Twenty-four hours after evaporation of silver iodide and after many ice and water depositions on the surface, its sublimation threshold dropped to − 5° C. After a week of use the threshold value was − 10° C. With larger silver iodide crystals the critical temperature is somewhat lower, and with a quite coarse, clearly visible silver iodide deposit is − 5·5° C. The ageing process of coarser surfaces is similar to the 'sensitized' surfaces.

Though the seeding ability of silver iodide is not as high as that of zinc or cadmium, evaporated *in vacuo*[3], the surfaces seeded with silver iodide have the great practical advantage of being relatively lasting and very easy to reproduce. Sublimation on the surfaces seeded with silver iodide commences at temperatures somewhat lower than the frost point of the air under investigation, that is, between the frost point and the dew point, though generally closer to the former. Even with a seeded surface, therefore, the frost point should be determined by observation of the temperature at which ice crystals *present* on the surface are in equilibrium with the air under test, and *not* by determining the temperature at which ice crystals first appear on the surface[4]. In spite of this, the process of humidity measurements at temperatures between 0° and − 60° C. by the use of surfaces seeded with silver iodide is much simplified. Hitherto, such measurements have required a rather skilled observer owing to the difficulty of distinguishing between ice and supercooled water, either of which may be deposited on an unseeded surface in this temperature range. On the seeded thimble, this uncertain region is restricted to only a few degrees below freezing, when the error due to confusion between saturated vapour pressure of ice and water would be relatively small.

I wish to thank Mr. H. D. C. Waters, lecturer in chemistry at this College, for preparing samples of silver iodide from reagents of analytical purity.

Radar Observation of Heavy Rain

IN view of the article on this subject which appeared in *Nature* of March 5, p. 372, it may be stated that the systematic exploration of clouds and rainfall by means of radar has been proceeding actively in Great Britain for some years past, though relatively little has been published, apart from official reports and memoranda. The photographs shown in the article referred to are characteristic of rainfall from a moving cold front.

Following upon successful experiments by the Telecommunications Research Establishment of the Ministry of Supply, a radar station at East Hill, near Dunstable, was taken over by the Meteorological Office for meteorological investigations. The station is equipped with A.M.E.S. Types 13 and 14 radar, operating on a wave-length of 10 cm. and using a pulse of 2-microsec. duration. The presentation on the display tube of the Type 13 gives range and height of the echo, while that of the Type 14 gives the bird's-eye view or PPI display. A simple switching device enables the Type 13 tube to be used to give the intensity of the echo, and in the cases under investigation the maximum intensity in the vertical column is usually examined particularly. Certain meteorological stations in the neighbourhood of East Hill are equipped for measuring rate of rainfall and drop-size, while the upper air data provided by the regular sequence of *radio sonde* ascents at the network in the British Isles are available to enable the phenomena to be related to the general meteorological situation.

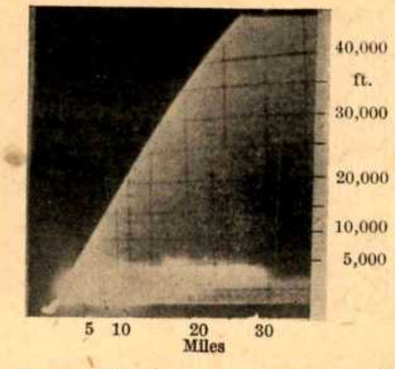

Fig. 1. January 29, 1948, at 1044 G.M.T.; bearing 246° T.

In addition, on selected occasions, the echo-producing clouds are simultaneously explored by an aircraft provided by the Royal Aircraft Establishment at Farnborough.

The object of the investigations is the study of the physical processes going on in clouds, including in particular the relation of the echoes to vertical currents and to icing which might constitute dangers to aircraft.

The results to date and earlier work which has been the subject of official reports cannot be described within the space available here; but two characteristic types of vertical sections are shown in the accompanying three photographs. Horizontal distance in miles is shown below the photographs and height in feet at the side.

Fig. 1, showing the 'bright band' effect, is found with layer-type clouds such as occur with weak and slow-moving or quasi-stationary fronts. Such bands are of limited vertical development, rarely giving responses down to ground-level and sometimes associated with a brighter band near the freezing-level. They are associated with relatively weak vertical air currents.

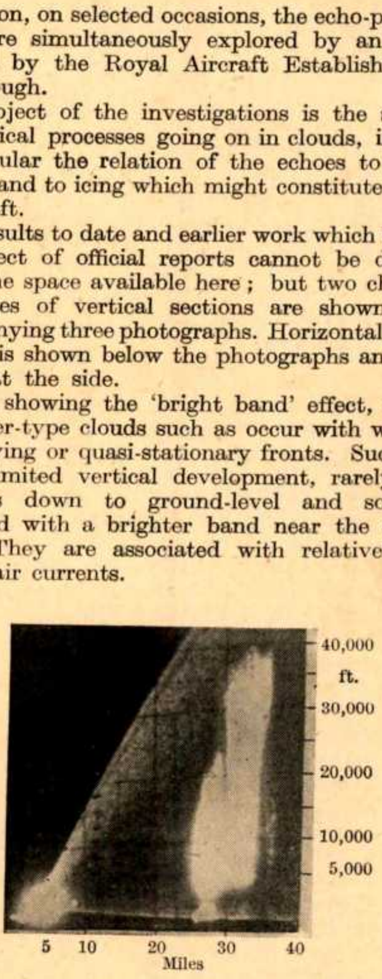

Fig. 2. July 30, 1948, at 1544 G.M.T.; bearing 194° T.

The outstanding feature of Fig. 2, on the other hand, is the appearance of strong vertical columns of echo, with clear-cut vertical edges and no indication of any 'bright band' phenomena. The more distant echo seen here comes from a thunderstorm extending to 40,000 ft., and the tendency to diverge near the top will be noted. The nearer echo was from a strongly developing new cumulo-nimbus. Such clouds have apparently liquid water drops at all heights, since they have been found to cause icing on the exploring aircraft.

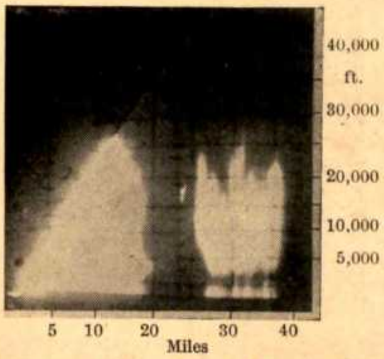

Fig. 3. June 10, 1948, at 0923 G.M.T.; bearing 176° T.

Fig. 3 relates to two extensive thunderstorms, one going on overhead and around the station, the other some 25–36 miles distant. The small isolated echo between at a height of about 17,000 ft. is from the observing aircraft, which is about to enter the second thunderstorm. In this case the accelerometer records from the aircraft appear to indicate that the peaks of the vertical columns were associated with strong upcurrents, the troughs with down-draughts.

This note is communicated by permission of the Director of the Meteorological Office.

Frictional Electrification of Dust and Pre-ignition in the Hydrogen Engine

THE experiments on the frictional electrification of sand described by E. W. B. Gill[1] are of interest in respect of the pre-ignition and combustion knock generally observed when hydrogen is used as the fuel for an Otto-cycle internal combustion engine. Pre-ignition in the hydrogen engine is defined as ignition occurring during the induction stroke, that is, before the inlet valve closes.

Engine experiments by R. O. King, W. A. Wallace and B. Mahapatra[2] demonstrated that the effects mentioned were not obtained in the absence of carbon dust derived from pyrolysis of the lubricating oil even at a compression ratio of 10 : 1 and when using hydrogen–air mixtures in any ignitable proportion.

The engine experiments were resumed in September last, when the laboratory atmosphere was heavily impregnated with dust arising from the breaking up of part of the concrete floor. Pre-ignition was so severe that they could not be continued.

An air cleaner from an 85-h.p. motor-car engine was then fitted to the air intake of the C.F.R. experimental engine, which aspirates about 1/15 as much air. There was then no pre-ignition, and combustion knock was reduced sufficiently to permit completion of the experiments. The cleaner was of the type in which, on change of direction of the air stream, the particles of dust are thrown on to a sticky surface. In view of the oversize of the cleaner, it may be assumed that the larger particles only were removed from the air stream.

The engine experimental results, if interpreted in the light of those described by E. W. B. Gill, indicate that pre-ignition in the hydrogen engine when aspirating dust-laden air is due to discharges of electricity as between larger particles carrying negative charges and small ones carrying positive charges, remembering that potential differences would be increased by the friction between particles due to the air–hydrogen mixture passing the restriction of the inlet valve at high velocity. The air cleaner removes the large particles and pre-ignition is prevented accordingly.

The 'Complex Indicatrix'

IN discussing the application of Drude's 'complex indicatrix' for reflected light, M. Berek[1,2] originally extended the use of this term to include the two sheets representing the separate values for n and k. Thus he says, "The [cubic] complex indicatrix consists of concentric spheres with radii n and k". Strictly, the cubic complex indicatrix is, as he states elsewhere, a sphere with the complex radius n-ik, and is not itself geometrically representable. The n and k surfaces are representable for the more symmetrical crystals though not for the general case, and in some ways these surfaces take the place of the indicatrix of a transparent crystal. Nevertheless, this use of the term 'complex indicatrix' seems too wide, and I think this is Berek's opinion, for on looking through his later summary (1937)[3], I have not been able to find the term so used, though there is no direct reference to the question. No special designation is used for the curves there plotted (pp. 59, 60) and I have recently cited these under Berek's former nomenclature[4]. A term such as 'representative surfaces' for n, k, R, etc. would, however, appear to be more satisfactory.

As often happens, differences in notation have arisen in the accounts given by different workers. Berek consistently employs k for absorption coefficient, $\varkappa$ for absorption index ($k = n\varkappa$). In the English translation of Drude[5] (p. 360) $\varkappa$ is termed the coefficient of absorption, but later (p. 371) it is called the index. L. Capdecomme and J. Orcel[6] use χ in place of Berek's k and term it the "indice d'extinction". R. Galopin[7] uses k in place of Berek's $\varkappa$ and terms nk the "coefficient d'absorption". I understand that a further discussion from the mathematical side may be available in the new edition of the "Lehrbuch der Erzmikroskopie", Bd. I.[1].

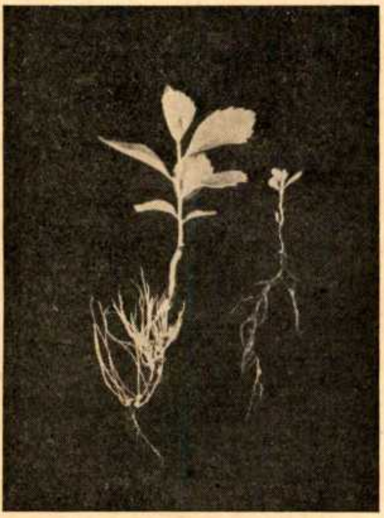
Root Nodules of Bog Myrtle or Sweet Gale (*Myrica Gale* L.)

PREVIOUS investigations[1] on the root nodules which commonly occur on *Myrica* spp. have referred chiefly to the structure and cytology of the nodules and to the identification of the endophyte. Little attention appears to have been paid to the possibility of fixation of nitrogen being associated with the nodules. Bottomley[2], after visual comparison of the growth made by plants (some with nodules, some without) transplanted from the natural habitat into a nitrogen-deficient soil, concluded that fixation of nitrogen had occurred. This finding deserves confirmation and amplification.

Satisfactory germination has been obtained with bog myrtle seed pre-treated by exposure in moist peat to a temperature of 2° C. for six weeks. Afterwards it was noted that this agreed with the experience of Barton[3] using seed of *M. carolinensis*. Seedlings were transplanted in May to water culture in Crone's solution (nitrogen-free formula, *p*H initially 5·0) and inoculated with a suspension of crushed nodules from field plants. Nodules appeared in three to four weeks. Seedlings not so inoculated did not develop nodules and showed very little growth, whereas all nodulated plants grew strongly (see photograph). Eight nodulated plants harvested after sixteen weeks growth in water culture showed a mean dry weight of 245 mgm. and a total nitrogen content of 7·3 mgm. per plant. Corresponding means for five non-nodulated plants were 6 mgm. and 0·1 mgm. respectively. These data strongly suggest that fixation of atmospheric nitrogen is associated with nodulated plants.

Young nodules developing under the above conditions show a red colour identical in hue with the pigmentation (presumably anthocyanin) which also appears in the hypocotyl of the seedling. A curious feature is that the roots which, in *Myrica* spp., develop from the tips of the nodules grow upwards (see photograph) and eventually project from the surface of the culture solution. The other roots display normal orientation. A parallel seems to be presented by the observations of McLuckie[4] on the tubercle roots of *Macrozamia*, which also exhibit upward growth.



Plants of bog myrtle (sweet gale) after twelve weeks growth in nitrogen-free water culture: left-hand plant with nodules, right-hand plant without nodules. × ½

This investigation, to be continued, is associated with work on leguminous root nodules which is receiving support from the Agricultural Research Council.

Preparing for the Occurrence of New Races of Rust

IN Australia within the last eight years there have been two important cases of the breakdown of resistance to rust in wheat. The first was in 1942 when Eureka 2, a variety which, up to that time, had been highly resistant, suddenly became susceptible. This new stem rust has, on account of its close relationship with race 126, been designated as race 126*B* (unpublished data). The second case was in 1945, when Gabo was attacked by leaf rust (*P. triticina*) for the first time in Australia. This is also a rust unlike those previously present.

Eureka 2 and Gabo have proved particularly popular with growers, for under rust-free conditions in northern New South Wales, both are capable of high yields, they have a good straw and give a flour of satisfactory quality. The incorporation of leaf-rust resistance into Gabo is receiving immediate attention, and despite the big reduction in acreage sown to Eureka, we are endeavouring to add stem-rust resistance to it. These programmes will not be completed for some years yet and serious losses from rust may occur in the interim. Moreover, changes in the rust flora may render Gabo susceptible at any time.

It seems that when such satisfactory varieties have been bred, steps should be taken to prepare them for the possible occurrence of new races of rust. Although it is impossible to breed for resistance to specific races until they appear, we are working to a programme which it is hoped will give reasonable assurance of having, in a few years, a series of varieties equal to Gabo and Eureka 2 in yielding ability, and comprising certain ones resistant to new races of rust when they arise.

The problem of adding stem-rust resistance to Eureka 2 is a simple one, and already we have obtained from a back-cross of Gabo × Eureka 2 three resistant lines that seem the equal of the recurrent parent. However, it is considered unwise to concentrate solely on the one source of resistance, as there is no certainty that Gabo will continue to be resistant in the event of another rust culture greater in its parasitic capabilities than race 126*B*. To prepare for such an eventuality, we are using, in addition to Gabo, a diverse collection of varieties for crossing with Eureka 2. Varieties in this collection are known to have a fairly comprehensive stem-rust resistance under Australian conditions and include the following: Hofed, Fedweb, Celebration, Charter, *T. Timopheevi* × Steinwedel, Kenya 117*A*, wheat × rye, Khapli Emmer × Steinwedel and *Triticum* × *Agropyron*. These and others are being crossed individually ith Eureka 2, and in each case the resistant progeny ill be back-crossed to Eureka 2 until sufficient of s genotype has been recovered. These recovered lines iould all be morphologically similar, but during the iurse of the selection it may be possible to include marker gene so that at a glance one can tell from hich source the resistance has been added. At :esent, it is not known whether all the resistant arieties given above have different genes for rust sistance. In at least certain of them, the genes opear to be allelic. Despite the absence of this iformation the programme will not be affected, for iould a new rust arise, then all those recovered nes that prove susceptible will be discarded. It most unlikely that all resistant progenies obtained om such a diverse collection of parents will succumb t one time to the same rust. One or more of the irviving ones will, of course, be released for cultivaon.

Preparing Gabo for the occurrence of a new strain f stem rust has not proved so simple, as this variety already resistant to the Australian races. Connuous back-crossing to Gabo, using, say, Kenya 17*A* as the non-recurrent parent, would probably nly recover the present Gabo resistance, unless there as available for test a specific race to which Gabo as susceptible. As such is not present here, and it eems unwise to introduce it, the programme is being arried out in two steps. The progeny of the Gabo × ureka 2 cross mentioned above has been back-rossed twice to Gabo and selection has been for tem-rust susceptibility. After one more back-rossing, probably sufficient of the Gabo genotype ill have been recovered. To this susceptible strain f Gabo will be added in turn the resistance of those arieties of the above collection. These recovered, esistant strains of Gabo, together with the resistant abo now being cultivated, should give some hope hat even if a new race of rust does arise, one or nore varieties will be immediately available capable f resisting it.

This programme is not being complicated by leaf-ust resistance at present, as this latter is a separate roject. It is proposed to combine leaf- and stem-ust resistance as soon as practicable. A method losely resembling the one outlined for Gabo and ureka 2 is being followed in breeding for rust resistnce in linseed. Punjab is taken as the standard usceptible high-yielding variety. The resistance of everal carefully selected parents is being added by he usual method of back-crossing.

Effect of Crude Benzene Hexachloride on Wheat Seedlings

There are numerous published references to the mfortunate effects of benzene hexachloride on the levelopment of plants, both from seed[1-3] and from he tuber[4]. In only one of these reports, however, s any reference made to the question of the exact dentity of the constituent of the crude material vhich is responsible for these effects[3]. Of the many somers and impurities present in the crude material, mly the gamma isomer is recognized as important is an insecticide. If the effects of benzene hexahloride on plants are due to some other constituent, the potentialities of the material as an agricultural insecticide may be greatly extended. To settle this question, experiments were begun in March 1948 by treating seed wheat with various preparations and constituents of benzene hexachloride, and observing the effects on germination and development.

The evidence indicates that plant deformation is not due to the gamma isomer. A mixture of trichlorobenzenes prepared by alkaline breakdown of alpha benzene hexachloride possesses this activity in far higher degree, relatively small doses causing the ultimate symptom, inhibition of germination. The material is active in the vapour phase. Possibly this active material is 1,3,5-trichlorobenzene, which has been shown to have this property[5], possibly another trichlorobenzene or some other volatile breakdown product of benzene hexachloride. Under natural conditions it is produced most rapidly by the breakdown of the gamma isomer, more slowly by the alpha isomer and at a quite unimportant rate, if at all, by the beta isomer. The material is effective in such low concentration that it may well have applications in the field of selective weed-killers. The exact nature of the material is still under investigation and detailed results will be published shortly.

Benzene hexachloride preparations for wheat-seed treatment against wireworms should be materials of high gamma content, applied at the minimum practical rate for control. The hazards accompanying their use are likely to be increased by storage after treatment, especially if ventilation is inadequate, by exposure to sunlight and by deficient moisture or high *p*H of the soil.

I am indebted to Dr. J. H. Whyte, of the Department of Botany, University of Alberta, for his help on botanical aspects of this work; also to Prof. D. L. Garmaise, of the Department of Chemistry, University of New Brunswick, and to Messrs. Canadian Industries, Ltd., who kindly provided many of the chemicals used.

Persistence of Pyrethrins and Gamma Isomer of Benzene Hexachloride

In view of Beckley's advocacy of pyrethrum dust for weevil control in bagged grain[1], the following comparison with the gamma isomer of benzene hexachloride is of interest.

Laboratory tests were made against *Sitophilus granarius* using wheat dusted with 0·5 and 1·0 p.p.m. gamma benzene hexachloride from a commercial benzene hexachloride dust diluted with kaolin, and with 5, 10, 20 and 27 p.p.m. pyrethrins from powdered pyrethrum flowers. The treated grain was kept in open jars for 2–16 weeks at 28° C. and 70 per cent relative humidity before introducing the insects, and the jars were then closed. Mortality counts were taken at intervals up to 28 days. The tests were run in quadruplicate and the usual precautions observed.

Period of airing before infestation. weeks	2		10		16	
Count made......days after infestation	10	28	10	28	10	28
Treatments and corresponding absolute mortalities, %						
Benzene hexachloride, gamma isomer, 1·0 p.p.m.	100	—	87	97	86	94
Benzene hexachloride, gamma isomer, 0·5 p.p.m.	95	97	43	61	10	17
Pyrethrins, 27 p.p.m.	76	81	28	38	3	1
Pyrethrins, 10 p.p.m.	8	12	9	8	—	0
Control, no dust	2	7	4	8	0	5

Results, detailed in the table, show not only that gamma benzene hexachloride at 0·5 p.p.m. is more toxic than 27 p.p.m. pyrethrins, but also that it is more persistent. The Agricultural Research Council finds that gamma benzene hexachloride at this dosage is free from health hazard.

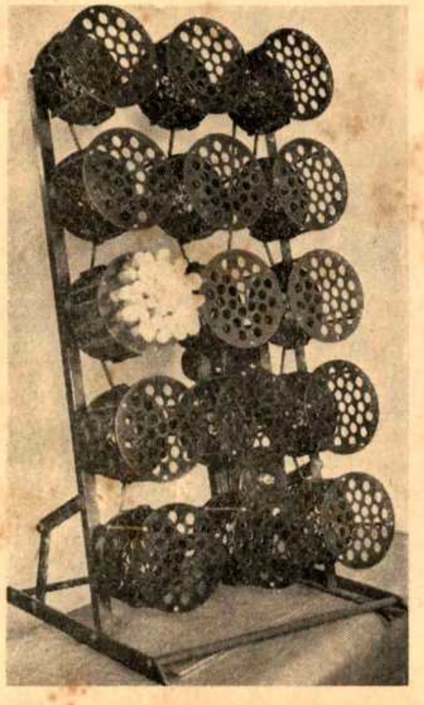
A Rotating Test-Tube Apparatus for Experimental Fermentations

THE examination of different species or mutants of moulds calls for a simple and compact apparatus in which fermentations can be conducted in large numbers. The 'shaken flask' technique[1] has proved of great value, but even this requires a good deal of space if many tests are to be carried out at the same time.

To meet this special need a simple apparatus has been devised by which a large number of test-tube cultures can be satisfactorily aerated by rotation.



Each unit consists of a rack composed of two 6-in. diameter disks separated by supporting rods 3½ in. long. Both disks are drilled with 31 oversize ⅝-in. holes to carry test-tubes of that size. The units are mounted on ball races to reduce friction and are driven from a pulley by a suitable drive. A convenient apparatus consists of fifteen such units mounted on a steel frame, as shown in the photograph. Such an apparatus will fit into a laboratory incubator and will permit 465 fermentations to be made simultaneously. The degree of aeration can be changed by altering the inclination of the tubes through 16°.

From numerous trials we found that, with 5-ml. media in each tube, an angle of inclination of 11·5° and a speed of rotation of 100–120 r.p.m. gave satisfactory conditions for growing *Streptomyces griseus*.

The growths and titres obtained in this way were comparable with those obtained by other methods of carrying out small-scale fermentation.

I wish to thank Dr. A. J. P. Martin for his suggestions, and Mr. L. C. Maltby for making the apparatus.

Another Little-known History of Botany

THE recent review by Prof. F. E. Fritsch[1] of "A Forgotten History of Botany" by Karl F. W. Jessen has reminded me of another little-known book on the same subject, published in 1871 in Paris, under the signature of "L. G.". It is entitled "Précis de l'Histoire de la Botanique", and is one of the seventeen volumes of the botanical encyclopædia "Le Règne Végétal" published by a group of botanists of that period. The author of the "Précis" is perhaps the editor of the encyclopædia, L. Guérin, whose name appears at the bottom of the title-page; but this is merely a guess based on the initials which are used. The book seems to have been inspired mainly by Pritzel's first edition of "Thesaurus literaturæ botanicæ" (1851), but the "Précis" is stated to contain the titles of numerous publications unknown to Pritzel, especially French publications.

The book contains 535 pages, and some supplementary maps on plant geography. Its subject-matter is chronologically arranged and covers the whole field of history, beginning with "Before the Greek Civilization" (Chapter 1) to the nineteenth century (Chapter 7). There is an index comprising the names of all the authors cited in the book.

This history of botany is probably not as readable as Jessen's, since long lists of names are rather frequent, especially lists of titles of publications. However, I feel that the book is useful for purposes of reference, and I have often made use of it. If some person could give me precise information about its author, I should be grateful.

THE OIL-DROP METHOD FOR THE DETERMINATION OF THE ELECTRONIC CHARGE

By Dr. V. D. HOPPER
Physics Department, University of Melbourne

It is generally accepted that the discrepancy between Millikan's[1] early value of the electronic charge, e ($4{\cdot}770 \times 10^{-10}$ E.S.U.), and the value derived by the X-ray method ($4{\cdot}8021 \times 10^{-10}$ E.S.U.[2]) can be accounted for by the uncertainty in the value of the viscosity of air at 23° C. (η_{23}). There exist, however, wide variations in the results obtained by different workers using the oil-drop method, even when the ratios $e^{2/3}/\eta_{23}$, which are independent of the absolute value of the viscosity, are compared. For example, the following values of $e^{2/3}/\eta_{23}$ have been derived from the results published by the authors: Millikan[1] $334{\cdot}96 \times 10^{-5}$; Bäcklin and Flemberg[3] $334{\cdot}12 \times 10^{-5}$; Ishida, Fukushima and Suetsugu[4] $336{\cdot}65 \times 10^{-5}$; Hopper and Laby[5] $335{\cdot}09 \times 10^{-5}$ (e E.S.U., η_{23} C.G.S.). In view of the large variation in these values, in spite of the internal consistencies of the separate experiments, it seemed desirable to make a systematic study of the oil-drop method itself, to find, if possible, the reasons for these differences and also an unexceptionable value of $e^{2/3}/\eta_{23}$.

In this study, the velocities of a drop were measured when acted on by the earth's gravitational field and by the combined action of the gravitational field and an almost vertical electrical field. The velocities were measured by photographing the drop with the aid of a spark which was triggered at intervals of 1/5 sec. The hole in the top plate of the condenser through which the oil drops entered the field of view was 0·368 mm. in diameter and displaced 2 mm. from the centre. Measurements of drop velocities were made in the centre of the condenser, a millimetre or so sideways from the hole, thus ensuring that the distortion produced by the hole on the electric field was negligible[6]. Care was taken to avoid an accumulation of oil on the lower plate of the condenser, as this also produces a field distortion. The condenser plates were slightly tilted in the direction of the optic axis of the camera, so that under the repeated action of the fields the drop was gradually brought into and finally out of focus. The plates were also tilted in a direction at right angles to the optic axis, so that the path of the drop took the form of a saw tooth across the field of view; and from a study of the photograph of the drop the position of best focus could be ascertained. It was also possible to repeat the process by displacing slightly the air in the apparatus, so that the drop was brought back to its original plane. The magnification of the camera was corrected for emulsion shift. Fig. 1 shows the path taken by an oil drop. The wavy sections of the path correspond to the small translation of the drop made to bring it back into focus.

In addition to the effect of the hole on the electric field between the plates, several other factors have been found to influence the experimental value of $e^{2/3}/\eta_{23}$ and are summarized here.

(1) *Purity of the air.* Measurements must be made soon after the admission of fresh air. With air which had been in the apparatus for several weeks, a value of $e^{2/3}/\eta_{23}$ was obtained which was consistently 0·3 per cent higher than that obtained with fresh air. This effect was attributed to impurities coming from the walls of the apparatus and contaminating the air.

(2) *Correction for the walls.* The correction to Stokes's equation due to the influence of the walls of the apparatus increases considerably the value of $e^{2/3}/\eta_{23}$ of some of the previous workers. An auxiliary experiment was carried out[7] which confirmed the Lorentz formula for the effect of a single wall on the motion of a falling oil drop.

(3) *Oxidation of the oil.* Results using Apiezon oil B and castor oil confirmed the conclusion of Ishida *et al.*[4] that oxidation or absorption occurs with oil in the form of very small drops. It was observed that using these oils the downward velocity of the drop when under the action of gravity increased gradually with time, whereas the upward velocity due to the combined action of the gravitational and electrical fields showed a decrease. Fortunately, the variations in these velocities tend to cancel each other in the determination of $e^{2/3}/\eta_{23}$, but a serious error might occur if a drop is studied for long periods after spraying. This effect could not be detected with butyl sebacate, and this oil was used for the determination. Fig. 2 shows the variation of velocities with time of two drops of Apiezon oil B (measurements for Fig. 2 B were taken from the drop photographed in Fig. 1), one drop of castor oil and one of butyl sebacate.

(4) *Impurities in the oil.* Erratic results occurred occasionally if the steel wire brush used for producing the oil drops was nearly dry. This was attributed to impurities in the oil. Some drops have been photographed which showed definite fluctuations in light intensity, due, it is believed, to small steel particles held in the drop. To reduce the possibility of impurities influencing the results, the brush was cleaned regularly and impregnated with fresh oil.

Fig. 1. Path of Apiezon B oil drop ($n = 22$ (electrons), $a = 3{\cdot}90\ \mu$) which had been refocused several times. The wavy sections correspond to the small translation of the drop made to bring it into focus

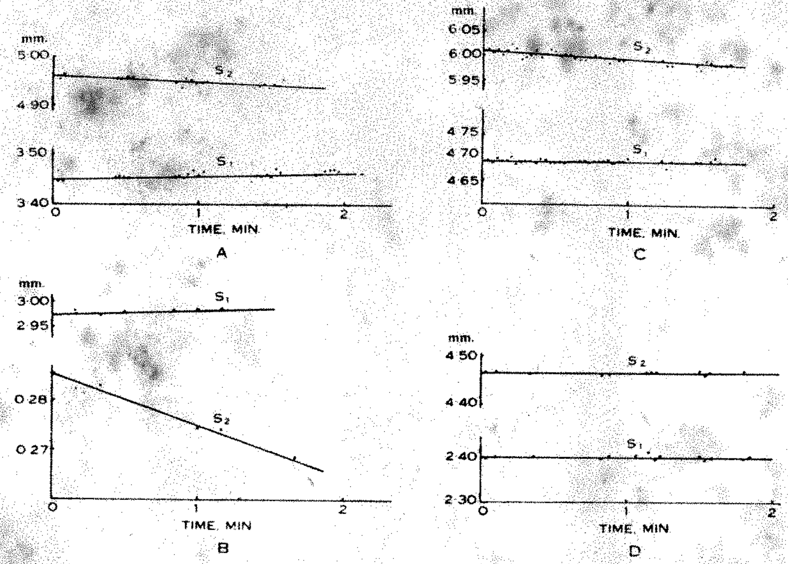

Fig. 2. Variation of drop velocity with time: (*A*) Apiezon oil *B*; (*B*) Apiezon oil *B*; (*C*) castor oil; (*D*) butyl sebacate. S_1 is proportional to the velocity of the drop when under the action of gravity; S_2 is proportional to the velocity of the drop when under the combined action of the gravitational and electric fields

Some of the above factors make marked changes in the values of $e^{2/3}/\eta_{23}$ previously quoted. The result of Bäcklin and Flemberg[3], namely, $334{\cdot}12 \times 10^{-5}$, which was the only one giving a value of $e^{2/3}/\eta_{23}$ agreeing with both the X-ray value of the electronic charge and Kellström's value ($1835{\cdot}0 \times 10^{-7}$ C.G.S.) for the viscosity of air at 23° C., is increased by the correction for the walls to $335{\cdot}03 \times 10^{-5}$. As no data were given regarding the size of the hole used in these experiments, the correction for this cannot be calculated; but it has been estimated that had a hole 0·6 mm. in diameter been used and measurements made below its centre, the above value of $e^{2/3}/\eta_{23}$ must be increased to $335{\cdot}9 \times 10^{-5}$. Following the criticism by Birge[2], the result of Hopper and Laby[5] has been recalculated. Using the same method of analysis for both the castor oil drops and the Apiezon oil *B* drops, the value of $e^{2/3}/\eta_{23} = 335{\cdot}13 \times 10^{-5}$ is obtained, whereas for the Apiezon oil *B* results alone the value is $335{\cdot}40 \times 10^{-5}$. The correction for the wall effect is uncertain, since in that experiment the plates were vertical, but it will increase these values by at least 3 parts in 1,000. (The actual correction may, however, be less than this as the purity of the air may be open to question.) Ishida *et al.*[4] were the only workers to make corrections for the change in density of the oil, and their value corrected for the effect of the walls becomes $336{\cdot}95 \times 10^{-5}$. A correction was necessary to this work owing to an error in voltage measurements[8]. From a recent private communication Prof. Ishida states that this correction, which was determined much later, was found to be as much as $-1{\cdot}1$ per cent. The experiment has been repeated by Ishida, Suetsugu and Matsui, giving, it is stated, $e = 4{\cdot}794 \times 10^{-10}$ E.S.U. ($\eta_{23} = 1{,}830 \times 10^{-7}$ C.G.S.), whence $e^{2/3}/\eta_{23} = 334{\cdot}72 \times 10^{-5}$. If the same correction for the walls is assumed for this as for the 1937 work, the value will be increased slightly to $335{\cdot}02 \times 10^{-5}$. Millikan's value will be increased slightly to $335{\cdot}10 \times 10^{-5}$ if the wall correction is applied. There is internal evidence in this work of a gradual variation in density of the oil, but a correction for this was not made.

In the present investigation, from measurements of forty-seven drops using voltages of 4,000 and 2,000, and for values of $1/pa$ ranging from 21·2 to 174·4, the value of $e^{2/3}/\eta_{23} = (335{\cdot}75 \pm 0{\cdot}11) \times 10^{-5}$ was obtained. Fifty-one values of $e_1^{2/3}/\eta_{23}$ (that is, values of $e^{2/3}/\eta_{23}$ uncorrected for the slip term[1]) from these forty-seven drops are plotted against $1/pa$ in Fig. 3. The value of $e^{2/3}/\eta_{23}$ corresponds to $1/pa = 0$ and will be increased slightly if Oseen's[9] modification to Stokes's analysis is applied, but the increase will be less than + 0·04 per cent.

A summary of the results of several careful determinations of the viscosity of air made since 1913 is given in the accompanying table. Derived values of η_{23} obtained from the corrected oil-drop values of $e^{2/3}/\eta_{23}$ (assuming $e = 4{\cdot}8024 \times 10^{-10}$ E.S.U.) are also tabulated. There is a wide variation between recently determined values of the viscosity, four of those tabulated being close to $1834{\cdot}2 \times 10^{-7}$ C.G.S. and the remaining two being close to $1829{\cdot}5 \times 10^{-7}$. The value adopted by Millikan for his 1917 work was $1822{\cdot}7 \times 10^{-7}$ C.G.S. The present investigation implies a value of $1826{\cdot}5 \times 10^{-7}$ C.G.S. if $e = 4{\cdot}8024 \times 10^{-10}$ E.S.U. is assumed for the electronic charge.

There is reason to believe that the electrical and mechanical measurements involved in the determination of the electronic charge by the falling drop method can be made with sufficient accuracy. The difficulties inherent in the measurement of the viscosity of air represent a greater limitation to the reliability of the method.

ACTION OF SURAMIN ON ENZYMES

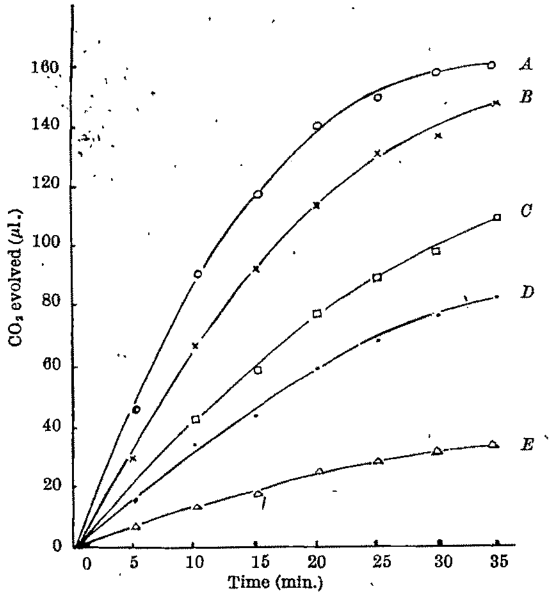
By Dr. B. W. TOWN, E. D. WILLS
AND
Prof. A. WORMALL
Dept. of Biochemistry and Chemistry, Medical College of St. Bartholomew's Hospital, London

WHEN injected intravenously, suramin (synonyms: 'Antrypol': Bayer 205; 'Germanin': Fourneau 309) quickly effects the removal of trypanosomes from the blood and tissues of man and other animals suffering from sleeping sickness due to *Trypanosoma gambiense* or *T. rhodesiense* infections, if the infection is not too far advanced. The precise way in which suramin exerts its specific action on the trypanosome or on the defence mechanisms of the host or on both is still unknown, although several theories have been advanced[1].

One possible explanation is that the drug combines with or otherwise inhibits enzymes in the trypanosome which are necessary for the normal metabolic changes in that organism. Trypanosomes consume considerable quantities of carbohydrates; it was found, for example, that trypanosomes can be kept alive *in vitro* much longer if glucose is added to the medium[2]. The rapid utilization of oxygen by the trypanosomes can easily be demonstrated by manometric methods, or more simply by keeping small samples of citrated blood from infected sleeping sickness patients and suitable controls out of contact with oxygen for a short time; the trypanosome-containing blood often becomes noticeably darker than the controls, owing to deoxygenation of the oxyhæmoglobin by the trypanosomes.

Any inhibition of this comparatively vigorous oxidative metabolism in the trypanosome might be expected to reduce its reproductive capacity and/or its resistance to the attack of the body defence mechanisms, and a knowledge of the action of trypanocidal drugs on enzymes might prove very useful. We are therefore studying the action of suramin on various enzyme systems, including those of the trypanosome, to determine whether concentrations of the drug similar to those reached in the blood of injected animals, or inside the trypanosome, are likely to prove toxic to any particular enzymes. So far we have largely confined our tests to the yeast enzymes concerned with carbohydrate metabolism and some other enzymes selected for particular reasons.

Previous investigators have studied the action of suramin on a few enzymes. In relatively high concentrations (0·007 *M*, that is, 1 per cent) the drug inhibits trypsin[3], and in $1·75 \times 10^{-4}$ *M* concentrations it was found to be toxic to the enzyme fumarase but not to urease[4]. Acceleration of post-mortem lactic acid production in muscle and liver has been reported[5], but retardation of blood glucolysis[6]. Hyaluronidase

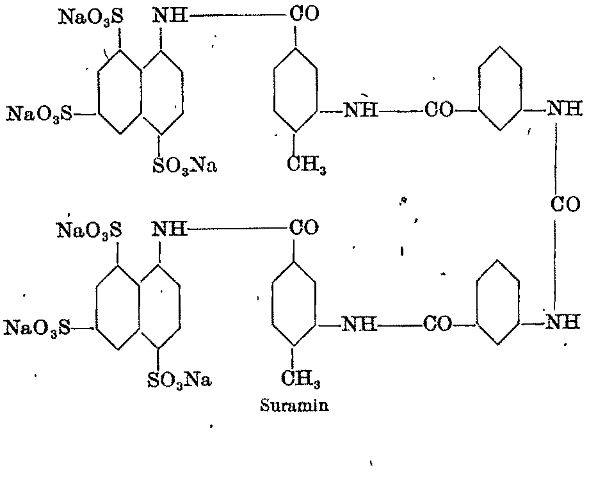


Inhibition of urease by suramin at pH 5·0. (Soya bean urease: 2·3 × 10^{-3} M urea; enzyme and drug in contact for 30 min. before suramin added)

A, no suramin; *D*, *M*/5,000 suramin
B, *M*/15,000 suramin *E*, *M*/3,000 „
C, *M*/7,500 „

has very recently[7] been found to be remarkably sensitive to the drug; 85 per cent inhibition of the enzyme is effected by 7 × 10^{-5} M suramin and 15 per cent by 7 × 10^{-7} M.

In our experiments we have found that although suramin has no inhibitory action on urease at pH 7·5 (thus confirming previous work[4]), marked inhibition occurs at pH 5; at this latter pH a final concentration of 3·3 × 10^{-4} M suramin gives 90 per cent inhibition, and 7 × 10^{-5} M suramin inhibits to the extent of 25–65 per cent (varying with the time of contact of drug and enzyme). A few typical results of these experiments are shown in the accompanying graph. The mechanism of this inhibition is still under investigation; but our results suggest that the suramin acts by competitive inhibition. This may be related to the presence of a urea structure in suramin, but it is also possible that the action of the drug on urease and other enzymes, like the combination with serum and other proteins[8], and the persistence of the drug in the animal body[9], is largely determined by the sulphonic acid groups of suramin.



Suramin

Very recently we learned that Dr. Madinaveiti of Imperial Chemical Industries, Ltd., has also bee carrying out investigations with suramin and ureas and that he has obtained results similar to our ow

Suramin combines with a variety of protein[1] particularly at pH 5 or in more acid solutions[8]. might be expected, therefore, that most enzym would be inhibited by suramin in acid solution, bu this is not so. The hydrolysis of plasma proteins b pepsin at pH 2 is not inhibited by 0·001 M suramin the fact that in precisely the same buffer solution pH 5 urease is strongly inhibited by suramin, wheres invertase is unaffected by the drug, is indicative the specificity of the inhibition. Furthermore, w have found that there are many enzymes which a not significantly inhibited by suramin.

In our experiments, trypsin (Harrington Bros Ltd.) has been found to be much more sensitive t the drug than was previously[3] reported; for exampl 0·001 M concentrations of suramin gave 30 per ce inhibition of the hydrolysis of casein, and 0·0005 M suramin gave 20 per cent inhibition at pH 8·9 and 30 Inhibition of this enzyme may be due to the similarit between the —NH—CO—NH— structure of surami and the peptide linkage of proteins, but further wor will be needed before this is fully established. Test are now being carried out to determine the effect, o urease, trypsin and other enzymes, of several surami analogues and similar compounds.

Since the metabolism of trypanosomes is largel concerned with carbohydrates, we decided to study by manometric methods, the action of suramin o the carbohydrate-metabolizing enzymes of yeast We have found that the drug strongly inhibits th fermentation of glucose by yeast juice, concentration greater than 2·0 × 10^{-5} M giving 100 per cen inhibition. This concentration is considerably les than that which is maintained in the plasma of rabbit for several hours or days after the injection o an amount of the drug equivalent to that use clinically; even after four days, for example, th level may still be 3·5 mgm. of suramin/100 ml. o plasma (equivalent to 2·5 × 10^{-6} M)[11]. Our stud of the effect of the drug on the individual enzyme of yeast is not yet complete, but it is hoped that i will provide a clue to the enzymes in the trypanosom which are likely to be affected by the drug.

We are grateful to the Medical Research Counci for a grant covering the expenses of these investigations. Thanks are also tendered to Dr. M. Dixo for samples of fructose diphosphate and adenosin triphosphate, to Dr. A. Spinks (of Imperial Chemica Industries, Ltd.) for samples of several suramin analogues, and to Miss Barbara Hume for help wit some of the manometric experiments.

DENSITY OF HEAVY WATER

By PROF. TSING-LIEN CHANG

AND

LÜ-HO TUNG

hemistry Department, National Tsing Hua University, Peiping

THE density of heavy water was accurately determined by Stokland, Ronaess and Tronstad[1] n the temperature range 10–27°. Measurements ere extended to 50° by Chang and Chien[2], and later y Wirtz[3]. Recently, we have further extended the measurement up to the boiling point of heavy water.

A 16-ml. quartz pycnometer consisting of a bulb ith a short stem of 0·5-mm. calibre and a ground-oint cap was used. A thermostat kept the temperature constant within 0·01°. Special precautions were aken regarding the pycnometry, thermometry, urification of water, avoidance of contact with tmospheric moisture, reduction of the weighings to acuum, and volume correction for the thermal xpansion of vitreous quartz. In order to make sure f the accuracy of our measurements, we have etermined the density of ordinary water between 0° and 100° and found that the results agree with hiessen's data[4] within three units in the fifth ecimal place.

Two ampoules of heavy water of different conentrations supplied by Norsk Hydro-Elektrisk vaelstof A/S were distilled under vacuum direct nto the pycnometer. The mole percentage of D_2O as calculated[5] from its density ratio d_{25}^{25} in comparon with ordinary water at 25°. The Norwegian eavy water is known[6] to contain 0·32 weight per ent D_2O^{18}. Three series of measurements were arried out on samples containing 99·71–99·77 mol. er cent D_2O at intervals of 5° between 25° and 00° with special attention to the temperature range bove 50°. The density ratio d_{25}^{25} of the sample was etermined before and after each series of measurements.

From the density values so obtained are subtracted hose of ordinary water at the corresponding temperatures. The difference of density between heavy ater and ordinary water is obtained by linear xtrapolation. In the extrapolation to 100 per cent H_2O with normal isotopic composition of oxygen, the xcess of the oxygen-18 water is included in the D_2O ontent. The possible error so introduced will not ffect the fifth decimal place of the density value.

The density differences at various temperatures ere smoothed by the graphical method. The mean eviation of the measured values from those of the moothed curve is 0·000 02 gm./ml. Using Swift's alue[5] for 5° and Tronstad's values[1] between 10° and 5°, we have prepared the accompanying table for he density of heavy water (d_{D_2O}) in the liquid state, overing the complete temperature range between its eezing and boiling point. Considering the errors om different sources, we believe that our density alues are accurate to 0·000 05 gm./ml. The density f ordinary water (d_{H_2O}) is also given for comparison, ogether with the density ratio of heavy and ordinary ater. This ratio has also a tendency to pass over a maximum as predicted by Chang and Chien. The emperature for such a maximum seems to lie not far bove the boiling point.

Temperature °C.	d_{H_2O} gm./ml.	d_{D_2O} gm./ml.	$d_{D_2O} - d_{H_2O}$ gm./ml.	$\frac{d_{D_2O}}{d_{H_2O}}$
3·8	1·00000	1·10538	0·10538	1·10538
5	0·99999	10555	556	556
10	9973	10595	622	625
11·2	9961	10596	635	639
15	9913	10583	670	678
20	9823	10530	707	726
25	9707	10440	733	764
30	9568	10319	751	798
35	9406	10169	763	827
40	9226	09992	767	851
45	9024	9790	766	871
50	8807	9565	758	888
55	8573	9319	746	902
60	8324	9054	730	913
65	8059	8771	712	924
70	7781	8471	690	933
75	7489	8154	665	940
80	7183	7821	638	946
85	6865	7472	607	950
90	6534	7109	575	954
95	6192	6732	540	957
100	5838	6342	504	960
101·4	5736	6229	493	960

The density values in the temperature range between 30° and 50° formerly determined in this laboratory[2] are slightly too high, and those of Wirtz too low, while Bridgman's approximate values[7] for 60° and 80°, which represent the only known data above 50° up to the present, are much too high.

Experimental details will appear elsewhere.

MATHEMATICAL ASSOCIATION

ANNUAL MEETING

FOR the first time, the annual meeting of the Mathematical Association was held outside London; at the invitation of the Association's Midland Branch, and with the generous co-operation of the University of Birmingham, which provided lecture theatres and hostel accommodation, the Association met at Birmingham during April 20–23.

Duties abroad prevented the president, Sir Harold Spencer Jones, Astronomer Royal, from attending the meetings. In his absence, Mr. A. W. Siddons presided over the business meeting on April 21, at which Mr. A. Robson, until recently senior mathematical master at Marlborough College, was elected president for the forthcoming year. Sir Harold Spencer Jones will give his presidential address next year, Mr. Robson having agreed to give his address this year to fill the gap. Under the title, "How they Learnt, 1600–1850", Mr. Robson traced the development in content and treatment of the mathematical curriculum in English schools during this period, based on a study of text-books and school records, particularly those relating to Christ's Hospital. Mr. Robson's investigations show that the common view that mathematics was taught entirely as an academic subject, with little relation to practical applications, is not wholly correct. Prof. S. Brodetsky, formerly of the University of Leeds, then gave a lecture on nomography, showing how the solution of equations and the performance of various types of calculation can be carried out rapidly and with reasonable accuracy by means of the alignment of points on scale-carrying lines. For the remainder of April 21, a programme of excursions and entertainment was provided.

The morning of April 22 was occupied with two lectures: Dr. W. M. Hampton outlined the mathematical investigations which have been made into certain practical problems in glass-working, showing a very fair correspondence between theory and practice. Prof. R. Peierls, of the University of Birmingham, spoke on "Mathematics—Dead or Alive ?", and emphasized a principle which has always been fundamental in the Association's policy, that mathematics cannot successfully be taught as a dead subject, but only as a living organism in contact with present-day developments, whether these be in the applications of mathematics to problems of importance in other sciences or in the extension of mathematical knowledge itself by current research.

Two valuable discussions filled the afternoon session. In opening the discussion on "A Realistic View of Main School Geometry", Mr. C. V. Durell proclaimed that geometry is a physical science, not a pattern of logical relations between mathematical abstractions ; but Mr. Robson, following Mr. Durell, maintained that a logical system of some kind must be developed in the later years of the school geometry course. In the following open discussion, there appeared to be some feeling among the younger teachers that the reaction against Euclid in the schools may be in danger of going too far. The other discussion, on "Alternatives to School Certificate Mathematics, with reference to Secondary Modern Schools", opened by Mrs. E. M. Williams (City of Leicester Training College) and Mr. R. C. Lyness, a Ministry of Education inspector, reflected the Association's close attention to the problem of mathematical teaching in the new Modern School, where there is a danger that content and method may be too closely a copy of content and method in the Grammar School, instead of being firmly based and developed on the functional needs of the Modern School.

In the evening, Mr. J. A. Petch, secretary of the Joint Matriculation Board, spoke on a subject of vital interest to teachers, "Statistical Treatment of Examination Marks". Mr. Petch described the mathematical methods used in dealing with large-scale external examinations in order to minimize variations, to standardize the markings of a panel of examiners who share the assessment of scripts in one subject, and to set up a standard of comparison between markings in different subjects. His audience welcomed his demonstration of the skill, care and patience devoted to the assessment of the merits of the School Certificate candidate.

On the morning of April 23, a first step was made on a programme which the Association hopes to follow up in later meetings, by getting speakers from outside Great Britain to deal with aspects of mathematical education in their countries. On this occasion, Mr. B. T. Gilroy, of New South Wales, and Mr. R. G. Keats, of South Australia, outlined the system of mathematical teaching in the secondary schools and universities of Australia. Dr. H. C. Christofferson, of Oxford, Ohio, described the ideals which inspire the teachers of mathematics in the high schools of the United States ; members of the Association supported his plea for a complete fusion of theory with practice, appreciated his illustrations of detail, and relished his fund of American anecdote.

A NEW FOSSIL GYMNOSPERMOU 'OVARY'

THE discovery of a new type of many-seede fruit body from the Lower Carboniferous Scotland is a matter of more than local palæobotanic interest. The publication by Prof. John Walton the full description of *Calathospermum scoticu* (*Trans. Roy. Soc. Edin.*, 61, 719 ; 1949), which h been awaited since the preliminary account in 1940 is therefore most welcome, although it is difficult withhold a protest that any learned society, so lo after the end of the War, should subject importa scientific work to the treatment recorded in t superscription "MS. received May 10th, 1947. Re May 3rd, 1948. Issued separately Feb. 11th, 1949

Calathospermum scoticum consists of isolated fru bodies of large size (up to 24 mm. × 45 mm.), shap like a tulip and each consisting of a cupule divid into six segments which surround either a centr mass of stalks or an equivalent number of stalk ovules. Compared with other known many-seed cupules (*Gnetopsis* and *Calathiops*), *Calathospermu* is the first to be discovered of Palæozoic age in whi the mode of arrangement of the ovules inside t cupule can be studied, thereby contributing son very interesting comparative facts to place beside t better known but much more recent *Caytonia*. T stalks in *Calathospermum* are partly borne on t margins of the cupule segments but also on a quad partite central column to which some twenty-four them may be attached. Each stalk has a centr vascular strand which is continued into the integ ment of the ovule and out into its appendages. T latter consist of nine terete apical projections considerable length which terminate the orthotropo ovules. In the form of these appendages and in oth characters the ovules themselves resemble ve closely those of *Salpingostoma dasi* described b Gordon in 1941[2], although they are thought to b specifically distinct. *Salpingostoma*, interesting enough, is itself the oldest structurally preserv seed which can be assigned with certainty to t Pteridosperms.

In attempting to interpret the presence of tw states of the fruit bodies, those containing ovules o badly preserved (and therefore perhaps immatur stalks and those containing well-preserved stalks b no ovules, the suggestion is made that the latter a probably in the more advanced developmental stat It is thought that, as the seeds ripened, their stal may have elongated and extruded them from t cupule, after which they became detached. Fro details observed in the histology of the cupule se ments it is thought that these may have opened o in a perianth-like manner during extrusion of t seeds, although in the water-logged condition pr ceding fossilization they had again closed.

The fruit body appears to have been borne on t end of a stalk containing a single crescentic vascul strand. It is therefore concluded that they we foliar and not axial appendages.

For the non-specialist reader a valuable com mentary on these facts will be found in the recent published Symposium on the Evolution and Class fication of the Gymnosperms held in Chicago i December 1947. Prof. H. N. Andrews's paper[3] i particular supplies a very valuable background i his survey of existing knowledge of Pteridosperms i general, while Prof. B. Sahni[4], by giving details another new Gymnospermous group, the Jurassic Pentoxyleæ, in which naked seeds with fleshy integuments are clustered directly on to a cauline cone axis totally devoid of any trace of leaf-like appendages, provides a wholesome corrective against the hasty generalizations which *Calathospermum* by itself might arouse in the unwary. Both *Calathospermum* and the Pentoxyleæ are, however, of first-rate theoretical importance in the phylogeny of the Gymnosperms, and both, therefore, merit the attention of a general botanist.

EUROPEAN CORN BORER IN NORTH AMERICA

THE European corn borer (*Pyrausta nubilalis*) was first found in the United States in 1917, among sweet corn near Boston, Mass., where it was infesting an area of at least 100 square miles. It was later found that the insect was also present at the same time near St. Thomas, Ontario. The actual date or year of entry of this dangerous pest into North America is uncertain, but circumstantial evidence points to its occurrence among broom-corn imported from Hungary or Italy between 1909 and 1914.

The insect is among the most threatening of all pests of Indian corn (or maize); accumulated knowledge shows that its eradication is not possible, but various cultural practices can be adopted so that there results a reduction in the losses caused by the insect. According to W. A. Baker and W. G. Bradley, entomologists of the U.S. Bureau of Entomology and Plant Quarantine, the damage caused by the borer in the United States in 1945 was estimated at 36,700,000 dollars. In a recent publication by these two entomologists* they state that infested areas extend all down the east coast and across the continent to districts west of the Great Lakes. The favourite plant host in America, as in Europe, is Indian corn (maize), but the insect also attacks beans, soybean, millet, oats, potatoes and some other cultivated crops. Garden flowers are also infested, notably dahlias, gladioli, zinnias, chrysanthemums and various weeds that grow among or bordering the maize crop. Among the Lakes States the corn borer is single-brooded and feeds almost entirely on maize, whereas in the southern and eastern parts of the infested region two or even three broods prevail, and the insects affect a wide range of different plants. The injuries it causes are effected during the larval stages when it tunnels into the stalk, main stem or mid-rib of its host-plant, as the case may be. As a result of the damage thus caused, much of the nutriment is cut off from the ear or flowering part, which weakens or flags and breaks.

As regards methods of controlling the borer, the indigenous insect parasites have proved of no avail. They number twenty-four different species, yet their combined activities have resulted in the destruction of only a fraction of 1 per cent of the borer. Large numbers of foreign parasites have been introduced from Europe and have established themselves, but it is premature to state whether they will prove to be effective controlling agents. At the present time the corn borer can be best controlled by utilizing or destroying all parts of infested plants before any of the insects they may contain are able to change into the adult or moth stage. Feeding affected crops to livestock either directly from the field or as silage is a valuable method. In other cases deep ploughing beneath the soil or complete burning of all infested vegetation before the spring when the moths appear is recommended. Any method that leaves behind living borer caterpillars among the plant residues merely provides for the infestation to go on during the following year. The use of insecticidal sprays containing D.D.T. or other toxic agents has been recommended for use during the period when the eggs are hatching, in order to destroy the young caterpillars.

---

* U.S. Department of Agriculture. Farmers' Bulletin No. 1548: The European Corn Borer; its Present Status and Methods of Control. Revised edition, by W. A. Baker and W. G. Bradley. Pp. 46. (Washington, D.C.: Government Printing Office, 1948.) 15 cents.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, May 9

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Prof. S. W. Wooldridge and Mr. S. H. Beaver: "Land Use and Surface Mineral Working in Britain".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. F. J. Cole: "Aspects of Biological Discovery, 2, Circulation of the Blood".*

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "Graphical Methods in Teaching Electrical Engineering (including Radio)" (to be opened by Mr. S. N. Ray).

Tuesday, May 10

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Mr. Tom Harrisson: "Human Studies in Central Borneo, 1945–49".

University of London (at the London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. D. V. Glass: "The Application of Social Research" (Inaugural Lecture).*

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. Barr and Mr. J. Erskine: "The Manufacture and Use of Stainless-Clad Steel".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. Jacques Tréfouël (Paris): "Some Advances in Chemotherapeutic Research at the Pasteur Institute".*

Illuminating Engineering Society (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Annual General Meeting; at 6.30 p.m.—An Address by Monsieur L. Gaymard.

Wednesday, May 11

Institute of Fuel, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 11 a.m.—Conference on "Combined Heat and Power Supplies".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Robert Broom, F.R.S.: "South Africa's Contribution to our Knowledge of Man's Evolution".

Universities Federation for Animal Welfare (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. Jean-Paul Harroy: "Nature Protection".*

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. F. Morton: "Examination of Crude Oils in relation to Geological Formations".

Physical Society, Low Temperature Group (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Discussion on "The Use of Thermodynamic Diagrams in Industry" (to be opened by Prof. D. M. Newitt, F.R.S.).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. E. K. Rideal, F.R.S.: "How Crystals Grow".

Thursday, May 12

Council for the Preservation of Rural England (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 2.30 p.m.—Annual General Meeting.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. H. Raistrick, F.R.S.: "A Region of Biosynthesis" (Bakerian Lecture).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

University of London (in the Great Hall, King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. V. Gordon Childe: "Social Worlds of Knowledge" (Hobhouse Memorial Lecture).*

Chemical Society, Hull Branch (joint meeting with the University College Scientific Society, in the Science Lecture Theatre, University College, Hull), at 6 p.m.—Prof. A. R. Todd, F.R.S.: "The Mechanism of Drug Action".

Chemical Society (at the Royal Institution, Albemarle Street, London, W.1), at 7.15 p.m.—Dr. E. Lederer: "The Chemistry and Biochemistry of some Mammalian Secretions and Excretions".

Friday, May 13

Physical Society, Optical Group (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 3 p.m.—Eighth Annual General Meeting; at 3.15 p.m.—Mr. C. E. Coulman and Mr. G. R. Petrie: "Notes on the Designing of Aspherical Magnifiers for Binocular Vision"; Lecture by Monsieur André Maréchal.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

University of London (at the Senate House, London, W.C.1), at 5.30 p.m.—Prof. A. C. Pigou: "Wage Statistics and Wage Policy" (Stamp Memorial Lecture).*

Saturday, May 14

British Psychological Society, Social Psychology Section (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 3 p.m.—Mr. M. D. Vernon: "The Significance of the Individual in the Social Group".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Experimental Officers at the Atomic Energy Research Establishment, Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2529 (May 13).

Physicist—The Secretary, Romford Group Hospital Management Committee, Oldchurch Hospital, Romford, Essex (May 14).

Senior Assistant in the Department of Civil and Mechanical Engineering, a Senior Assistant in the Electrical Engineering Department, and a Senior Assistant in the Department of Applied Chemistry—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1 (May 14).

Teacher of Electrical Engineering, a Teacher of Physics, and a Teacher of Building and Structural Design—The Principal, College of Technology, Belfast (May 14).

Senior Assistant to teach Civil and Mechanical Engineering subjects to Honours Degree standard—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (May 14).

Lecturer in Physics and Physical Chemistry at Birkenhead Technical College—The Director of Education, Education Offices, 63 Hamilton Square, Birkenhead (May 14).

Lecturer in the Department of Chemistry, and a Lecturer in the Department of Physics and Mathematics, Liverpool College of Technology—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (May 14).

Regional Director in the County Extension and Advisory Service of the College, an Assistant County Organiser, an Assistant Lecturer in Agricultural Engineering and Surveying, and a Lecturer in Horticulture—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (May 15).

Scientific Officer (Chemist) in the Food Infestation Control Section in Glasgow of the Department of Agriculture for Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.271/49A (May 16).

Electrical Engineer (Third Assistant grade), an Electrical Engineer (General Assistant grade), a Mechanical Engineer (Second Assistant grade), a Physicist (Second Assistant grade), a Physicist (General Assistant grade), and a Chemist (Second Assistant grade), in the Laboratory at Leatherhead—The Director of Establishments, British Electricity House, Great Portland Street, London, W.1 (May 16).

Principal Scientific Officer to control research and development of radio and radar navigation devices and aircraft approach and landing aids, a Principal Scientific Officer to control research and development of radio communication systems, etc., and a Senior Scientific Officer for the development of components for new radio equipments, in the Ministry of Supply, London—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2520 (May 18).

Research Assistant (Grade II) in the Library—The Director and Secretary, Science Museum, South Kensington, London, S.W.7 (May 21).

Lecturer and an Assistant Lecturer in Geology—The Registrar, University College, Singleton Park, Swansea (May 28).

Entomologist to the West Indies Cacao Research Scheme, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (May 28).

Research Officer—Heat Laboratory (Ref. No. 1918), and a Research Officer—Wool Research Laboratory (Ref. No. 1919), in the Division of Physics, Council for Scientific and Industrial Research, Sydney—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (May 28).

Lecturer in Zoology, and an Assistant Naturalist in the Dove Marine Laboratory—The Registrar, King's College, Newcastle-upon-Tyne (May 28).

Lecturer in Electronics—The Head of the Electrical Engineering Department, City and Guilds College, Exhibition Road, London, S.W.7 (May 30).

Graduates (preferably those who have taken Mathematics or Physics to an advanced stage) for Junior and Senior positions in the New Zealand Meteorological Service—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (May 30).

Lewis Cameron Fellow and Lecturer in the Department of Bacteriology—The Secretary, The University, South Bridge, Edinburgh 8 (May 31).

Research Assistants (with good honours degree in Physical Chemistry) for work on the physical and chemical aspects of selective flotation, a Lecturer in Mining, and a Lecturer in the Extra-Mural and Social Studies Department—The Registrar, The University, Leeds 2 (May 31).

Chair of Industrial Metallurgy, and the Second Chair of Chemical Engineering—The Secretary, The University, Birmingham 3 (May 31).

Readership in Physical and Inorganic Chemistry at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 1).

Reader or Senior Lecturer in Economic Geography—The Registrar, The University, Manchester 13 (June 3).

Superintending Anthropologist, Department of Anthropology, Calcutta—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, quoting No. 446.E (June 11).

Lecturer (Grade II) in Tool Engineering and Metrology, and a Lecturer (Grade II) in Industrial Statistics—The Secretary, The University, Birmingham 3 (June 15).

Tube Investments Research Fellowship in the Department of Engineering Production—The Secretary, The University, Birmingham 3 (June 15).

English Electric Company Bursaries in Hydro-Power Engineering—The Deputy Registrar, City and Guilds College, Exhibition Road, London, S.W.7 (June 30).

Assistant Professor of Pharmacology in Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (June 30).

Lecturer in Chemistry—The Warden and Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London, W.C.1.

Departmental or University Demonstrator for Research in Agricultural Production and Farm Organisation, and a Departmental or University Demonstrator for Market Research and Analysis—The Secretary, Agricultural Economics Research Institute, Parks Road, Oxford.

Education Lecturer in the Department of Hygiene and Public Health—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Histological Technician for cancer research work in the Laboratory of the Department of Anatomy—The Secretary and Registrar, The University, Bristol 8.

Lecturer in the Department of Mathematics, and a Senior Assistant Lecturer in the Department of Electrical Engineering and Physics—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Bursaries (3) for research in Physical Chemistry, tenable at the Imperial College of Science and Technology—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Laboratory Technician to assist with a fundamental research programme on the physics of rubber—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

Director of the West African Building Research Organisation—The Under-Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1.

FUNCTIONS OF A UNIVERSITY

THE efforts of the United Nations Educational, Scientific and Cultural Organisation during the last two years to promote educational reconstruction in Europe have in recent months assumed fresh importance, and indeed they have been strengthened. As the European recovery programme progresses and the project for Western Union takes shape, the key position of Germany in both becomes more manifest, from the point of view of defence and of economic affairs. Moreover, the place which Germany takes in the new Europe depends not only on the structure of Europe itself but also on the character of the new Germany.

In the shaping of that new Germany, the German universities have a decisive part to play. A new Germany responsive to the tradition of Western Europe, and able to take her place in a partnership of democratic peoples, can only follow from a fuller understanding of that tradition and of the nature of democracy, and the efforts of leaders inspired by a respect for intellectual freedom and for individual personality which was so conspicuously absent under the Nazi regime. If the universities of Germany are to provide such leaders and to make their essential contribution to the re-education of Germany, they have to purge themselves from the debased standards introduced under the Nazi regime and to restore the old tradition of scholarship and respect for truth and freedom of inquiry.

The shock which the academic world as a whole received through the surrender by the German universities of their *Lehrfreiheit* under a totalitarian regime and their failure to defend with any vigour their right to independence of thought, investigation and utterance—all the more remarkable because of the German idea of a university as a place devoted primarily to the pursuit of knowledge—led directly to the formation of the Society for the Protection of Science and Learning. The activities of this body, with the war-time conferences of the Association of University Professors and Lecturers of the Allied Countries in Great Britain and the Conference of Allied Ministers of Education, had an important influence in the formation of the United Nations Educational, Scientific and Cultural Organisation itself. These movements have stimulated much wider general concern with another function of a university, to which the Germans paid little attention, namely, that of instilling the culture of a society into its future leaders.

Great Britain, through its responsibility for one of the Zones of Occupation in Germany, has a special interest in the extent to which the German universities can contribute to the democratic development of the German nation. At the beginning of the Allied occupation, the British hoped that the universities would be one of the architects in shaping the new German society. It was early recognized, moreover, that that contribution could only be made after a drastic reform of the universities, and not merely after they had been purged of the Nazi elements which had debased their standards. Something much more than mere repair or physical reconstruction was required.

The task of reform is essentially a matter for the German people themselves: it cannot be imposed from without. The Occupation Authorities must, however, bear some large measure of responsibility for providing the conditions in which reform and reconstruction are possible. That was essentially the purpose of the Commission set up by the British Military Governor in the spring of 1948, although it was concerned directly only with the universities and technical colleges in the British Zone. It was not to be concerned with the present plight of German universities, their ruined buildings, their destroyed libraries, their lost endowments and the poverty of their students. It was solely concerned with the shape which the Commission hoped the universities might assume in the future. The recommendations of the Commission are thus primarily a matter for the German people. Reform must come from within, and it is the way in which the Commission's report is received in Germany that is of the first importance. Nevertheless, for the reasons already indicated, the report is one well worthy of study by the British universities, as the summary recently published in these columns (*Nature*, April 9, p. 552) shows, while passages in the recent book by Sir Walter Moberly, "The Crisis in the University", further emphasize its relevance to the supernational character which to some extent every true university must possess. As Sir Walter says rightly, university people recognize ties and obligations which transcend national frontiers and are not to be dissolved or suspended by the fiat of any national government: "For the due performance of its function the university must be recognized as an independent spiritual organ of the community".

For that reason alone, any reform of the German universities which might enable them in future to offer effective spiritual resistance to doctrines threatening the roots of their independence and functions of teaching and research cannot but be a matter of close concern to free universities everywhere. They will examine the Commission's recommendations with interest and be ready to help at any point where the German universities may seek aid. As Lord Lindsay of Birker, one of the two non-German members of the Commission, has already indicated, the insight into German universities which the report of the Commission gives may well bring fresh inspiration to British universities as they consider anew what should be the ideal and functions of a university in a modern community.

The German universities were at one time justly famous for their freedom and the individuality in research, which, under the influence of von Humboldt, they have encouraged since the early years of the last century. The Commission was rightly concerned whether this ideal of the university as the home of free research was capable of re-adaptation to modern times. If the German universities can regain their tradition of *Lehrfreiheit* and *Lernfreiheit*, it must also be considered whether the isolation of the universities from a great part of the population and of public opinion can be remedied, and whether a finer conception of the relations of teaching and research can be extended to inspire the leaders in social life. These are questions independent of national frontiers, and they are shown as clearly by Sir Walter Moberly as in the Commission's report.

Nor is this all. The Commission not only desires to see the universities brought again into the main currents of German social life; it also visualizes greatly increased facilities for study for students of limited means, in line with the increasing opening of the universities of Great Britain, through the extension of scholarships and awards. Its recommendations for experiment with a 'studium generale' to teach the unity of culture and counteract the dangers of specialization and the divorce of technology from social awareness have much in common with Sir Walter Moberly's observations; and the suggestion for a university council to promote closer relations between the university and all sections of the population is an interesting German adaptation of the constitution of the universities of the British Isles. If this proposal is adopted, its development will be watched with interest, not least in respect of its bearing on the contribution of the universities to the cultural and intellectual life of the surrounding community.

The proposal in the Commission's report for a wider conception of the function of the university teaching staff, which places the teacher alongside the research worker as his fellow, is the biggest departure from the von Humboldt ideal. The suggested new teaching posts, carrying the status and privileges of the traditional scholarly 'Dozent' and 'Professor', give the most emphatic expression to the conception of the function of a university which the Commission enunciates at the start: "to serve mankind by the teaching of that truth which comes from scientific research into reality".

The whole trend of the report is thus in line with the trend of opinion elsewhere regarding the place of the university in the modern world. This report is unanimous, and its proposals well designed to enable the German universities to recover their prestige. Its interest for British readers may cause some to regret that the Commission did not go further into the earlier history of the German universities and trace the reasons for the difference in development of German and British universities, in spite of their similarity of pattern in the Middle Ages. Nevertheless, the report is a real contribution to the studies of universities in the modern world to which Sir Walter Moberly has just made so valuable a contribution in Britain. Although, like Sir Walter, the report says little on the question of numbers in relation to the maintenance or even raising of standards, it shows that the Commission is keenly aware of the grave problem presented by the prevailing current of cynicism among the student population, and not in Germany alone. The new note of wide emphasis on the service of mankind may help to dispel such cynicism and fill that mental and spiritual vacuum. The labours of the Commission should bring new hope and fresh purpose, too, to all those bodies like

German Educational Reconstruction which are experimenting with academic relations between Germany and Britain; there is room for more experiments like the recent Oxford conference of economists and economic administrators from both countries arranged by that body. The free circulation of professional learning is a great safeguard against the atrophy of academic institutions, and a powerful stimulant of those supernational relations which nurture the noblest ideals of university life and work.

INDIAN INDUSTRIAL DEVELOPMENT

The Wealth of India

A Dictionary of Indian Raw Materials and Industrial Products. Raw Materials, Vol. 1. Pp. xxvii+254+39 plates. 15 rupees; 24*s*. Industrial Products, Part 1. Pp. xii+182+8 plates. 8 rupees; 12*s*. (New Delhi: Council of Scientific and Industrial Research, 1948.)

IT may occasion some surprise to those men of science who are ill-acquainted with India, and who so frequently express the view that Governments are unappreciative of the importance of science, to learn that as far back as 1886 the Government of India arranged for Dr. George (later Sir George) Watt, professor of botany in the Presidency College, Calcutta, to prepare a "Dictionary of the Economic Products of India". The six volumes of this standard work were published during the years 1889–99. In 1908 Sir George Watt published a condensed version, "The Commercial Products of India". Whatever the defects of these 'dictionaries', they have been of inestimable value to all interested in Indian natural products.

At the time of their publication, agriculture was the main Indian industry, and there were few others of any substantial size. In fact, prior to the First World War, there were only the textile industries, cotton and jute, since the great Tata Iron and Steel Works, which owed so much to the enthusiasm of the late Sir Thomas Holland, were still in process of erection. The partial isolation of India during the First World War and the demands of the Services, more especially for the Mesopotamia campaign, caused considerable expansion which should have been stimulated by the admirable report of the Indian Industrial Commission. Unfortunately, political dissension and economic difficulties led to the pigeon-holing of its major recommendations. It remained for the repercussions of the Second World War to make India realize once again the urgent necessity of setting up within her own boundaries the basic industries. Of much importance was the realization that this could only be achieved if her scientific man-power was fully mobilized.

For this purpose a Council of Scientific and Industrial Research was constituted with Sir Shanti Bhatnagar as the director of research. Later, this was reconstituted as the Department of Scientific and Industrial Research. In meeting the immediate war-time problems the need for a new edition of Watt's "Dictionary" was naturally felt, and in 1942 an advisory board and editorial staff, with Dr. B. L. Manjunath as the chief editor, was appointed to undertake its preparation.

We have now before us in vol. 1 not merely a new edition of Watt but a completely new work entitled "The Wealth of India: a Dictionary of Indian Raw Materials". The first volume covers subjects *A–B*, and it is anticipated that five further volumes will be published. As is not unnatural, the majority of the 220 articles deal with botanical subjects; but the field which has been covered is remarkably wide. As would be anticipated, the various articles are not of equal merit; but a high standard is maintained throughout, and the articles contain adequate literature references. As an indication of their value, mention may be made of the lengthy account (fifteen pages) on groundnuts, to which so much attention has recently been given. It is somewhat startling to read that on some of the Government research stations in India yields of 1,744 lb. per acre from the rain-fed crop and 3,328 lb. from the irrigated crop have been recorded, while in Madras the average annual yield is 990 lb. per acre. This article is worthy of careful study by those responsible for the growing of groundnuts in British Colonies.

Of interest also, in view of the increasing shortage of pulp suitable for the manufacture of paper, is the article on bamboo. Owing largely to the work of Raitt at the Forest Research Institute, Dehra Dun, where a pilot plant was erected in 1924, the difficulties encountered in using this material were overcome. In 1944–45, 62,300 lb. of bamboo pulp were manufactured in India; but unfortunately the pulp is costly, and it is therefore used in admixture with rag, grass or chemical pulp.

The wide field which is covered by vol. 1 may be indicated by mentioning that even the ornithologist will find much of interest in the article on "Birds".

The book is fully illustrated with many coloured plates, and it is printed on excellent paper, while the price is very reasonable. It reflects the highest credit on the chief editor and his staff. We look forward with pleasure to the appearance of further volumes, which will be indispensable to all who are interested in natural products.

It is somewhat more difficult to understand exactly to whom the volume "Industrial Products" will appeal. According to the introduction, "the primary purpose of the new work should be to secure fuller utilisation of Indian materials by Indian industrial and commercial interests and therefore it should also include Indian industrial products. . . . In the articles on these subjects an attempt is made to trace the development of various industries in India and to describe their present position."

We have, therefore, in this volume articles on such diverse subjects as acetylene, alcohol, alkalis, aluminium, boots and shoes, brass and bronze ware. The accounts are excellent, giving in suitable cases a full description of the chemistry or metallurgy, together with statistics of the present production in India. The articles are accompanied by illustrations of the factories recently erected in India. Apart from their references to Indian conditions, better accounts of many of the industries are to be found elsewhere. Useful as these volumes may prove to be for Indians, we feel that they are likely to have little appeal elsewhere, more especially since much of the information which they contain must very soon be out of date. Like the "Dictionary of Indian Raw Materials", the book is excellently produced.

In conclusion, we should mention that, although these dictionaries are published by the Government of the Dominion of India, we have, for convenience, used the term India in its old connotation, since in general their contents will appeal equally to the two Dominions, India and Pakistan.

A CAREFUL STUDENT OF HISTORY

The Meaning of Human History

By Morris R. Cohen. (Paul Carus Lectures, Sixth Series, 1944.) Pp. ix+304. (La Salle, Ill.: Open Court Publishing Company, 1947.) 4 dollars.

"It is not well to give an affirmative answer without examining the meaning of the question and making some necessary distinctions." Such prudence in dealing with vague concepts of the meaning of human history, with the numerous alleged 'laws' and explanations of the growth of human society, was very much in the character of the late Morris Cohen's writing. Lucid, careful in distinguishing, ready to postpone acceptance of a solution of a problem if it had no more to commend itself than that it solved part of the problem, these were the intellectual merits manifested in all his writing; and they are manifested in these posthumously published Carus Lectures.

Morris Cohen was not totally unimpressed by the claims of some of these systems of historical prediction or explanation. "Various theodicies, systems of evolution, and physical, political, economic, or other interpretations of history have all tried to make the endlessly complicated web of history conform to a pattern based on some happy guess." Morris Cohen did not deny importance to happy guesses; what he did deny was that a guess was more than a guess or that any of these systems answered all the questions which an intelligent observer of human society is forced to put to himself. Biological and physical conditions are of great importance, but they cannot explain all that puzzles us in the growth of human society. Religious beliefs, economic organisation, even that much despised category 'great men', all play their part. But they do not play the whole part. Few writers were less affected by mere fashion, or by the prestige or the lack of it attaching to any particular doctrine.

Morris Cohen was not easily impressed, and among the great names that in this connexion fail to impress him greatly, or at all, are Hume, Bacon, Marx, Freud, Karl Pearson, Croce. Nor are doctrines more reverently handled. Crude forms of determinism which, if examined, turn out not to be deterministic; what passes for the history of science (a theme he returns to again and again); simple-minded views of progress; all are examined and their weaknesses made plain. But his disregard for fashion works the other way, too, in the defence of the social contract theory, in the almost lyrical praise of the scientific pioneers of the University of Padua, in the affirmation of ethical claims with which the lectures end. No reader of these lectures will end them without having been forced to think a little more clearly on the question of historical causation, on the necessary conditions of certain types of intellectual progress, on social institutions like the city.

It is human to note that Morris Cohen did no always observe his own rigorous canons of historica proof. It is difficult to see how (on his principles) we can even guess that "there is probably less happiness in Europe to-day than in the eighteenth century, or even in the nineteenth". Nor is the statement that "Germans have changed their character in historic times, e.g. since Kant" invulnerable to the kind of criticism Cohen directed against rash generalizations based on the selection of arbitrary examples and too confident use of correlations. The population of Prussia, when it was still almost entirely agricultural cannot have been as dense as is stated on p. 183. It would (if these figures are right) have been as densely populated as modern Belgium or modern Saxony. If square miles are replaced by square leagues, it is intelligible. Then, Chamisso and La Motte Fouqué do not make the point against naïve race doctrines of nationality nearly as well as do other Germans of French origin, Savigny, von Verdy du Vernois, von Arnaud de la Perière, or Du Bois Reymond. It is the printers, presumably, who mis-spell Schrödinger and Lecky. Morris Cohen gave no comfort to the enthusiasts who thought and think that the growth of human society can be studied in the manner, and with the presumption of results, that we are accustomed to in the physical sciences. But he was convinced that it could be studied with profit, to the enlargement of our social imagination, to the understanding of our problems and to the reinforcement of our belief that there is ethical progress and that its chief enemy is not brute force but "negligence in the pursuit of the right".

PRACTICAL AND DESCRIPTIVE ASTRONOMY

Practical Astronomy

By Prof. Jason John Nassau. (McGraw-Hill Astronomical Series.) Second edition. Pp. xii+311. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 30*s*.

New Handbook of the Heavens

By Hubert J. Bernhard, Dorothy A. Bennett and Hugh S. Rice. (Whittlesey House Publication.) Revised edition. Pp. xi+360. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 18*s*.

Astronomy

By William T. Skilling and Robert S. Richardson. Revised edition. Pp. xi+692. (New York: Henry Holt and Co.; London: Chapman and Hall, Ltd., 1948.) 28*s*. net.

Worlds Without End

By Sir H. Spencer Jones. Revised edition. Pp. xv+262+32 plates. (London: English Universities Press, Ltd., 1948.) 10*s*. 6*d*. net.

PROF. J. J. NASSAU'S book is intended for students in civil engineering who have had no other course in astronomy, and for other students who wish to do some observational work to supplement the theoretical side of their study. This second edition incorporates revisions and additions, which have resulted in a fifty per cent increase as compared with the first, published in 1931. Part 1 deals with fundamental principles and ordinary determinations of time, latitude and longitude, as well as with the instruments used for these purposes. Part 2 presents all the advanced material necessary for field-work in geodetic astronomy, and includes a description of the modern astrolabe and its use in determining the geographical position of the observer. The book is adequately illustrated and is a most useful handbook that should satisfy all the needs of those for whom it is intended. The fact that it is designed for use with the "American Ephemeris" need not deter readers in other countries, as the tables required are similar to those published in other national ephemerides. Moreover, the ones needed for working out the examples given in the book are reprinted at the end of the volume.

The three remaining books are popular descriptive expositions of general astronomy. The first, "New Handbook of the Heavens", is apparently intended for the layman with no previous knowledge of the subject. The style of writing varies from one part of the book to another, the result presumably of multiple authorship. Certain of the chapters could be read with pleasure and profit by any keen amateur astronomer; but the treatment of others is so elementary and the terminology so over-simplified as to provoke the suspicion that use has been made of material originally intended for purposes of nursery instruction. Any reader who can stand up to this will find the book interesting enough, especially as, in addition to giving a simple general survey of the universe, it justifies its title by the inclusion of maps of the stars, lists of objects worthy of observation and hints on the use of a small telescope. A list of future eclipses and a short glossary of technical terms are useful features. Here and there are some misleading statements, as, for example, where the reader is told that a 9 to 12-in. telescope with a power between 400 and 500 is needed to reveal the disk of Uranus, and that Pluto is a difficult object in a 15-in. refractor. But these are small blemishes in a book that is likely to prove attractive and useful to the beginner in observational astronomy, and in any case it cannot do less than whet his appetite for something more advanced.

In Messrs. Skilling and Richardson's "Astronomy" we have something much more in the nature of a general text-book, albeit of an elementary and non-mathematical kind. It is, in fact, one of the best of its type and deserves the success which it has enjoyed since the first edition was published in 1939. As often happens in such books, the treatment of the various subjects is rather uneven; but probably there has never yet been produced a general astronomy on which a specialist will not have some criticism to make of the presentation of his own particular branch of the science. In this book, for example, the chapters on the sun and on solar and stellar spectroscopy seem to be particularly good, whereas other parts of the subject are less satisfactorily treated. Among minor errors is the incorrect statement of the modern meteoric theory of the formation of the lunar craters; and, in spite of several good and authoritative accounts of Herschel's life that have been published, the reader is given to understand that the astronomer was knighted by George III on the occasion of the discovery of Uranus, whereas, in fact, the honour was conferred on him by the Prince Regent some thirty-five years later, when he was quite an old man. A drawing and some photographs of Mars, made presumably from lantern slides, have been reversed east–west and are thus scarcely recognizable. But in spite of all defects the book remains an excellent general astronomy. Some of the illustrations are particularly good.

Of the Astronomer Royal's book, "Worlds Without End", which, like the three already mentioned, is a revised edition, it will be sufficient to say that it is the ideal popular sketch to put into the hands of any person, young or old, who is in need of a simple introduction to a profound subject. Though it is free from mathematics, it is packed with interesting facts, and the information contained in it has been brought right up to date. The treatment of the subject is remarkably lucid; and the illustrations are adequate, though one or two of them have not been very well reproduced.

W. H. Steavenson

SPIRITUAL HEALING

George Fox's "Book of Miracles"

Edited with an Introduction and Notes by Henry J. Cadbury. Pp. xvi + 162 + 8 plates. (Cambridge: At the University Press, 1948.) 21*s.* net.

It was over a quarter of a century ago that *Nature*, in discussing the report of the committee on spiritual healing set up in accordance with Resolution 63 of the 1920 Lambeth Conference, said that the committee had set aside or failed to solve "problems of the greatest magnitude and importance from the scientific point of view". Ten years previously, another clerical and medical committee had issued a report on which precisely the same judgment could legitimately have been pronounced, while to-day we are still in the same state of ignorance in spite of the activity among us of at least two 'spiritual healers' claiming remarkable powers.

In view of these facts it is interesting to cast the mind back to the work of the Quaker leader, George Fox (1624–91), whose manuscript "Book of Miracles", now lost, has been partially reconstructed through the labour of Dr. George Cadbury, who, in the present volume, has given us the result of his work. In "The Annual Catalogue of George Fox's Papers", which was made in 1694–98, an index was appended, and in this are included notes of the entries incorporated in the "Book of Miracles" which provide clues to the nature of the fuller accounts in the lost manuscript. By collecting these entries and supplementing the meagre information they supply from other sources, Dr. Cadbury has succeeded in presenting a tolerably clear account of the book and the nature of the miracles with which it dealt. In addition, he has printed an admirable summary of the situation as regards Quaker miracles, especially those relating to healing and kindred remedial measures.

Perhaps one of the most striking features of Fox's account is the absence of any flamboyant or spectacular claims to cure clearly organic diseases. Just as was the case with the committee of 1924, so here we are led to the provisional conclusion that little evidence is to be found that the alleged miracles cannot be paralleled in ordinary modern psychotherapeutics or in cases of spontaneous healing recognized by medical science. The kernel of the controversy is easy to discern. In the report of the committee of 1924 the theological section was naturally inclined to the view that the source of the healing power was *external* to the patient, while the medical and scientific members looked rather to an activity *within* the patient although manifestly put into motion through external stimuli. In the case of George Fox and the Quaker healers, this belief in Divine intervention was clearly implied in the "Book of Miracles", and the same may be said of many modern healers who believe their success is due to the operation of 'spirit doctors', with whom they are in some mysterious manner connected but whose powers they in no wise control.

For those who want a clear summary of the state of spiritual healing in George Fox's day, Dr. Cadbury's volume is essential, and he is to be congratulated on the care with which he has prepared his scattered material and the fascinating manner in which he has presented it.

E. J. DINGWALL

STUDY OF MOLECULAR STRUCTURE

Contribution à l'étude de la structure moléculaire

Dédiée à la mémoire de Victor Henri par R. Audubert, R. F. Barrow, A. Burawoy, C. A. Coulson, L. Couture, M. de Hemptinne, M. L. Delwaulle, J. Duchesne, J. Franck, F. François, P. Goldfinger, H. v. Halban, M. B. Hall, A. Kastler, V. Lasareff, J. Lecomte, M. Letort, M. Magat, C. Manneback, J. P. Mathieu, A. Mertens, H. Moureu, M. Niclause, L. Pauling, M. H. Pirenne, I. Prigogine, B. Rosen, H. Sponer, M. J. Stallcup, P. Sue, H. W. Thompson, E. E. Vago, A. D. Walsh, E. Warhurst, K. Wieland, R. Wurmser. Préfacé par L. Brillouin et par J. Duchesne. Pp. xiii+314. (Liège: Maison Desoer, 1948.) N.p.

THIS volume has been prepared in commemoration of Victor Henri, who died in 1940. V. Henri occupied the chair of physical chemistry at the University of Liège for almost ten years, and he developed there a remarkable school of molecular spectroscopy, kinetic chemistry and photochemistry. The twenty-seven papers in this book elaborate topics in which he was interested. The concept of predissociation was introduced by V. Henri following his discovery of a diffuse appearance in the discontinuous structure of certain spectra, and so it is particularly pleasing to record that two of the papers in this collection are devoted to this subject.

No attempt will be made here to discuss the papers in detail, but some trends may be noted. A large proportion of the papers are concerned with spectroscopy, and the majority of these discuss work on the infra-red and Raman spectra, while a few are devoted to the ultra-violet and visible régions. There are two papers on reaction kinetics. The equilibrium postulate which occurs in the theory of absolute reaction-rates is examined in one paper, while the other is concerned with the possibility of systematizing the treatment of certain chain reactions. The editorial committee has not attempted to present a balanced review of molecular structure, and, as a result, an examination of subjects such as X-ray diffraction, electron diffraction and dipole moments is not made in this volume. Theoretical papers on the atomic radius of carbon, cross-terms in the potential functions of polyatomic molecules and the calculation of bond-lengths are included. These contributions illustrate recent advances which have resulted from the extension of the work of Mulliken, Pauling and others. The paper presented by Burawoy, entitled "The Supposed Existence of Non-localised Electrons, Resonance and Stereomerism", is in sharp contrast with this series. Burawoy argues that the theory of resonance is in disagreement with numerous facts, and he supports the view that all constitutive changes are accounted for by inductive electronic displacements.

Inspection of the list of names of contributors should be sufficient to recommend this work, but it must be admitted that much of the substance of some of these papers has appeared elsewhere.

THE BRITISH PHARMACOPŒIA

The British Pharmacopœia 1948

Published under the direction of the General Council of Medical Education and Registration of the United Kingdom. (Published for the General Medical Council.) Pp. xl+914. (London: Constable and Co., Ltd., 1948.) 45s. net.

"THE British Pharmacopœia" was first published in 1864, and revisions appeared in 1874, 1885 1898, 1914 and 1932. The seventh edition, which was issued in 1948, is a great advance on its predecessors. The world is much indebted to the Pharmacopœia Commission and particularly to its chairman, Prof. J. A. Gunn, and to its secretary Dr. C. H. Hampshire, both of whom have served the Commission for many years. They helped to produce the edition of 1932 and have been primarily responsible for the issue of six addenda during the difficult days of the War and for the fine book now before us. A large number of other people have made lesser contributions, and more than fifty papers have been published in scientific journals to record the results of investigations undertaken at the request of the Commission.

This Pharmacopœia represents more work than any of its predecessors; it is good to know that most of this work was undertaken from a sense of public duty without hope of personal gain. The book has grown from 713 to 914 pages. One innovation is the admission of a number of substances still protected by patent rights; another is the inclusion of the structural formulæ of many organic substances The list of tablets was greatly extended in the addenda and has now been still further increased, so that there are about fifty different preparations of this sensible type. The 1932 edition contained only six 'injections', and the number has now grown to seventy-five. This reflects a change in therapeutics; but the increase is not as large as appears at first sight, since some preparations (such as pituitary extract) have joined this group by changing their names, and others (such as neoarsphenamine) have for long been given by injection without the dignity of a separate monograph.

Doses are still given both in the metric and Imperial systems. It is to be hoped that the Commission will soon decide that the time has at last come to drop the older system altogether, as other pharmacopœias have done; the present state of affairs is confusing and absurd. New drugs are generally described in grams or mgm., older drugs in drachms or grains. The older physicians have always been reluctant to learn metric doses and have taught the older system to their juniors. If the Commission took a strong line, there would no doubt be a bitter outcry at first; but the final result would be good.

J. H. GADDUM

James Clerk Maxwell, F.R.S., 1831–1879

By Dr. R. L. Smith-Rose. (Science in Britain Series: Published for the British Council.) Pp. vi+34+7 plates.

Lord Kelvin

By A. P. Young. (Science in Britain Series: Published for the British Council.) Pp. vi+42+7 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1948.) 1*s.* 6*d.* net each.

THESE are two welcome additions to the "Science in Britain" series, published by the British Council; for no survey of British science would be complete without some account of James Clerk Maxwell and Lord Kelvin, two of the great figures of the nineteenth century, and of the work which is associated with their names.

Maxwell's name is inseparably connected with his great achievement, the electro-magnetic theory of light, and many are familiar with the story of how, starting from the earlier, non-mathematical speculations of Faraday on the mechanism of propagation of magnetic disturbances, he reached the conclusion that the velocity of the impulses is the same as that of light. The prediction was afterwards verified experimentally by Hertz; and the practical consequences which have flowed from the application of Maxwell's theory of wave propagation are now widely appreciated. Dr. R. L. Smith-Rose has written an excellent short survey of the life and work of this great theoretical physicist, including also some account of his contributions to molecular physics and the kinetic theory of gases.

Kelvin was a man of a different stamp. Although he made theoretical advances in the field of thermodynamics, the importance of his work lay rather in the application of his wide knowledge of physical principles to invention. Besides his work on the fundamental electrical units and on the construction of precise electrical measuring instruments, which has proved to be of outstanding importance, he made valuable contributions in the field of instrument design to the art of navigation, among them the improvement of the mariner's compass; and he was one of the pioneers in the laying of the Atlantic cable. In his later years Kelvin as a physicist found difficulty in accepting the modern developments in physical theory; and Mr. A. P. Young's essay shows how his prejudices and limitations in this respect contrast with his outstanding achievements in the field of engineering in which he was supreme.

T. M.

Whitehead's Philosophy of Time

By William W. Hammerschmidt. Pp. ix+108. (New York: King's Crown Press; London: Oxford University Press, 1947.) 11*s.* 6*d.* net.

ONCE again, the King's Crown Press has done good service to scholarship in producing this monograph. Of all the great thinkers, Whitehead is one of the most difficult to read: this is not wholly because his thought is so profound, but partly it is on account of his use of a very special vocabulary. In addition, his views on Nature were undergoing continuous transformation, which resulted in some of his terms connoting different things at different periods of his life. Nowhere is this tendency more marked than in his philosophy of time, and for that reason alone Dr. W. W. Hammerschmidt's monograph would be welcome. As it is, on many other scores it should prove its worth, not least because we have here an attempt to bring some logical order into Whitehead's prodigious output. One would not desire, or indeed expect, regimentation to be characteristic of so sublime a creative artist; but his commentator has done well to stop short of organising the master's work more thoroughly than he seemed to intend.

So far as time is concerned, Whitehead throughout maintains something of an empirical basis, or, at least, he does for the fundamental properties of space-time. What undergoes progressive change is the place accorded to the nature of immediate experience. The present author keeps this dynamic aspect in true perspective as he unfolds the scene leading up to and through the Theory of Process.

Books *about* great men and their lives are apt to be disappointing; this one avoids that sensation, largely because it is impersonal and self-forgetful. It will help those who wish to study "experience dominated by emotion and experience under self-restraint" as time rolls onwards.

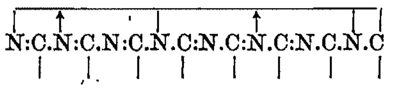
F. I. G. RAWLINS

The Chemistry of Organic Cyanogen Compounds

By Vartkes Migrdichian. (American Chemical Society, Monograph Series, No. 105.) Pp. ix+460. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1947.) 72*s.* net.

THE American Chemical Society was wise in devoting No. 105 in its monograph series to organic cyanogen compounds, for they find ever-increasing application, both in research and in technology. Indeed, the review may even be overdue, for Dr. V. Migrdichian has found it necessary to restrict himself rigidly to the *reactions* of organic cyanides. Thus, the physico-chemical attributes of the group find no mention, and preparative methods for even the most important nitriles are summarily dismissed, sometimes, unfortunately, with obsolete methods.

Within these limits the book is well conceived. Each typical reaction of the cyanogen group is selected and surveyed in turn to produce a condensed and comprehensive whole. Indeed, the amount of work reported is quite astonishing, and to some extent the review is correspondingly valuable. While the scope is satisfactory, the review, however, lacks an adequate critical approach to its material. This has resulted in errors, a certain irrationality within the chapters and at least one complete contradiction within the space of a few lines. The adoption, in part, of the *Chemical Abstracts* system of reproducing graphic formulæ has produced some surprising results without saving much space. Will many readers recognize the beautiful symmetry of the phthalocyanine molecule in the following guise:



$$\mathrm{N{:}C.N{:}C.N{:}C.N.C{:}N.C{:}N.C{:}N.C.N.C}$$

Indexing is extensive and complete, but the irrationalities of the book are reflected and form a trap for the unwary. For example, there are a number of references to acrylonitrile and others quite separate and unco-ordinated to vinyl cyanide. The numerous errors of reproduction are more appropriate to a galley proof than to an expensive work of this nature.

STANLEY L. THOMAS

A Scheme of Qualitative Organic Analysis

By Dr. Frederick J. Smith and Emlyn Jones. Pp. vii+320. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1948.) 17*s.* 6*d.* net.

THE student of organic chemistry will find in this book an excellent presentation of qualitative organic analysis along familiar lines. After application of the tests for elements and the usual preliminary examination, classification tests enable the experimenter to assign the substance under investigation to its class. Confirmatory tests are then made, and crystalline derivatives prepared by means of which the substance is finally identified. Many valuable tables are provided listing individual members of the various classes, with their physical constants, and suitable derivatives for their identification. The range of these tables is more comprehensive than is usual in a book of this standard. Numerous up-to-date tests have been included, and the reviewer has noticed very few errors apart from a confusion between m.p. and b.p. in the headings of several tables.

It is not to be expected that full details of microtechnique should be given, yet it would have been worth while to include a description of a micro-filter, which is so easy and cheap to assemble and so useful in dealing with the small amounts of material often isolated in preparing derivatives. The book is admirably produced and well indexed, and it will be found useful in many laboratories. G. M. B.

Fatty Acids and their Derivatives

By A. W. Ralston. Pp. ix + 986. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1948.) 60*s.* net.

DR. A. W. RALSTON must be congratulated on the production of this excellent volume, for there are few features in the long and tangled history of the fatty acids which have escaped his notice or defied his logic.

In his first five chapters he has regimented the one-time ruck of fatty acids to orderly array and paraded them for our benefit. Group by group those acids containing more than six carbon atoms are described—saturated, ethylenic, acetylenic, hydroxylic, ketonic, cyclic and dicarboxylic, all are there, with occurrence, isolation, synthesis and physical properties carefully portrayed. The naturally occurring fats, oils and waxes are considered only incidentally as sources of the acids. In the second section of his book Dr. Ralston describes the preparation, physical and chemical properties, and certain uses of the fatty-acid derivatives. Successive chapters describe, first, those derivatives not involving modification of the carboxyl group, then the esters, the nitrogen-containing derivatives, the alcohols, ethers, mercaptans, sulphides and sulphonates, the anhydrides, acid chlorides, aldehydes and ketones, the hydrocarbons and the metallic soaps. Then, since the ordering of so much material cannot be instantaneous, Dr. Ralston has provided an appendix to bring his survey up to date.

In the face of so much excellent material it is ungracious to criticize, and if, occasionally, Dr. Ralston may be thought to over-simplify a little, he has provided a more than adequate bibliography through which one may pursue any chosen line. This carefully written and well-indexed volume will come to be a trusted friend to all workers in the field.

How Greek Science Passed to the Arabs

By the Rev. De Lacy O'Leary. Pp. vi+196. (London Routledge and Kegan Paul, Ltd., 1948.) 15*s.* net.

THE title of this book is perhaps somewhat mi leading, for much the greater part of it occupied by a clear and scholarly account of th general history of the Near East during the perio between the conquests of Alexander and the tent century A.D. The book thus presents valuab material for the student of the science of this period but the emphasis is on the background rather tha on the science. A work intended for the gener reader should give some account of the nature an extent of the scientific knowledge that passed fro the Hellenistic world to Islam; but, in fact, he do not find much beyond the names of works, with man of which he may be unfamiliar. The reviewer note with some astonishment that the author does not much as mention alchemy or chemistry, the transf of which presents interesting and important problem on which a good deal of work has been done. Th proof-correction of the book is much at fault; suc errors as Antonius for Antoninus, Ultianus f Ulpianus, may mislead the reader and must sha his confidence in the correctness of the many nam he will meet for the first time in these pages. Th author cites a few formulæ in illustration of India and Arab mathematics; these appear in forms erroneous as to be scarcely recognizable. In spite these defects, which might easily be removed in second edition, the book satisfies a real need giving a compact account of a period which, while is little studied except by specialists, is of the fir importance to the historian of science.

The New Pictorial Encyclopædia. (*Daily Ma* School-Aid Publication.) Pp. 112. (London Associated Newspapers, Ltd., n.d.) 7*s.* 6*d.* net.

Look and Learn

The New Pictorial Encyclopædia. Series 2. (*Dai Mail* School-Aid Publication.) Pp. 112. (London Associated Newspapers, Ltd., 1948.) 7*s.* 6*d.*

INCREASING emphasis on visual methods learning have prompted the School-Aid Pu lications Department of the *Daily Mail* to issue series of books in which the role of the text an illustrations in the usual text-book are reverse Here the 'story' is told by means of photographs an diagrams, the text being introduced incidentally supplement the interest built up by the illustration This novel approach is undoubtedly one which h much to commend it and one which will be pa ticularly well received by teachers of more backwa pupils in primary, secondary modern and day co tinuation schools. But the publishers should bewa lest the interest they create through their pictur leads quickly to a state of mental confusion in t readers. In one book alone they include thirty-o topics, each of which is packed with informati which needs time to consider. The impression gain is that topic succeeds topic without any clear d marcation, so that some not-so-bright student mig easily include the Tower of London as a bra instrument of the orchestra. The books would ha greater effect if fewer topics were included and dea with at greater length. The pattern for these mig be based on the stories of America and Austral which are included in these books and which ha been excellently devised and elaborated. T. H. H.

SOLAR FLARES AND THEIR TERRESTRIAL EFFECTS[*]

By Dr. M. A. ELLISON
Royal Observatory, Edinburgh

THERE is no more fascinating problem in astrophysics at the present time than that of the rigin of solar flares and of the remarkable train of vents to which they give rise.

It is less than twenty years since Hale (1931)[1] lirected attention to chromospheric eruptions as a haracteristic type of solar activity. In recognizing heir influence upon terrestrial magnetism he called or priority to be given to their study in the co-perative programme of spectrohelioscope observaions of the sun's disk in hydrogen light then being rganised under the auspices of the International stronomical Union. The term 'flare', later proposed y Richardson, has gained general acceptance, though éruption chromosphérique' is still employed on the ontinent to denote the same phenomenon.

A 'flare' may be described as a sudden, short-lived ncrease in monochromatic radiation occurring in a imited region of the chromosphere and in the vicinity f an active sunspot group. Flares are classified on a isual scale of importance, 1 (smallest) to 3 (largest), higher 3+ category being reserved for those of reatest area and intensity and which are accomanied by marked geophysical disturbances. They ccur within a radius of 100,000 km. of a visible unspot and most frequently between the leading and ollowing components of a bi-polar group. The atches of bright emission have a life-time varying rom five minutes to one hour or more; in appearance hey range from the smallest points of light visible n the spectrohelioscope, covering only a few nillionths of the sun's visible hemisphere, to great white-hot' ropes and filaments (Fig. 1) which may tretch right across and obscure the largest of sunpots (area $\sim$ 5,000 millionths, or 5,860 million quare miles). The rise to peak intensity for a flare nay be extremely rapid, sometimes occurring as a lash' of radiation followed by a slow decay. Photonetric measures of the intensity in $H\alpha$ light, or neasures of the effective width of the $H\alpha$ emission ne, provide suitable means of following quantiatively the characteristic sequence of light variation. evelopment curves, such as that shown in Fig. 2 ower), reveal the very brief duration of the flash hase which occurs in the early stages of an intense are; the existence of this had previously not been etected by visual observations alone. These curves lso form a valuable standard of comparison when e seek to correlate flares with their ionospheric and eomagnetic effects. Moreover, any working hypohesis of flare generation should have, as one of its rimary aims, to account for this peculiar type of ght-curve.

Flare Spectra

The rarity of intense flares, their sudden and nexpected onset and their short duration all conpire to defeat the most patient spectroscopist. The w records which have been secured[2-5] indicate that ares of comparable $H\alpha$ intensity produce similar, hough by no means identical, spectra. The chief atures in the visible region are the bright reversals in the Balmer absorption lines of hydrogen, in neutral helium and in the lines of ionized calcium, iron, silicon and a few other metallic atoms. The hydrogen emission lines are often of great width, like that photographed at Sherborne (Fig. 3*a*) near the time of peak intensity of the 3+ flare on July 25, 1946. In contrast to this, however, the reversals of the *H* and *K* lines of ionized calcium and of the other metallic lines are much narrower. This circumstance points to the Stark effect[6] rather than the Zeeman effect as a possible cause of the wide wings seen in the hydrogen lines during the 'flash' phase. If this proves to be the correct explanation, we may infer that there exists for a short time in the flare region a high concentration of electrons, such as might accompany a large-scale discharge or 'lightning flash', taking place in the complex electric and magnetic fields known to exist in the vicinity of a sunspot.

Towards shorter wave-lengths, less than 3000 A., the solar spectrum is completely blotted out by the ozone and other absorptions occurring in the lower layers of our atmosphere. We have, therefore, as yet no means of recording directly the spectral characteristics of flares in the ultra-violet region. The recent extension of the Fraunhofer spectrum down to 2100 A., by means of spectrographs borne aloft in *V2* rockets[7], though a remarkable technical achievement, is of little value to the flare spectroscopist. His heavy apparatus would need to be raised at least 200 km. above the earth's surface and to be held in accurate alignment on a small and uncertain point of the sun's disk until the moment of opportunity arrived. However, the lines of hydrogen and helium in the visible region, coupled with the ionospheric effects of flares, enable us to infer the presence in emission of the Lyman series of hydrogen ($L\alpha$ 1215 A., $L\beta$ 1026 A., etc.) and of the

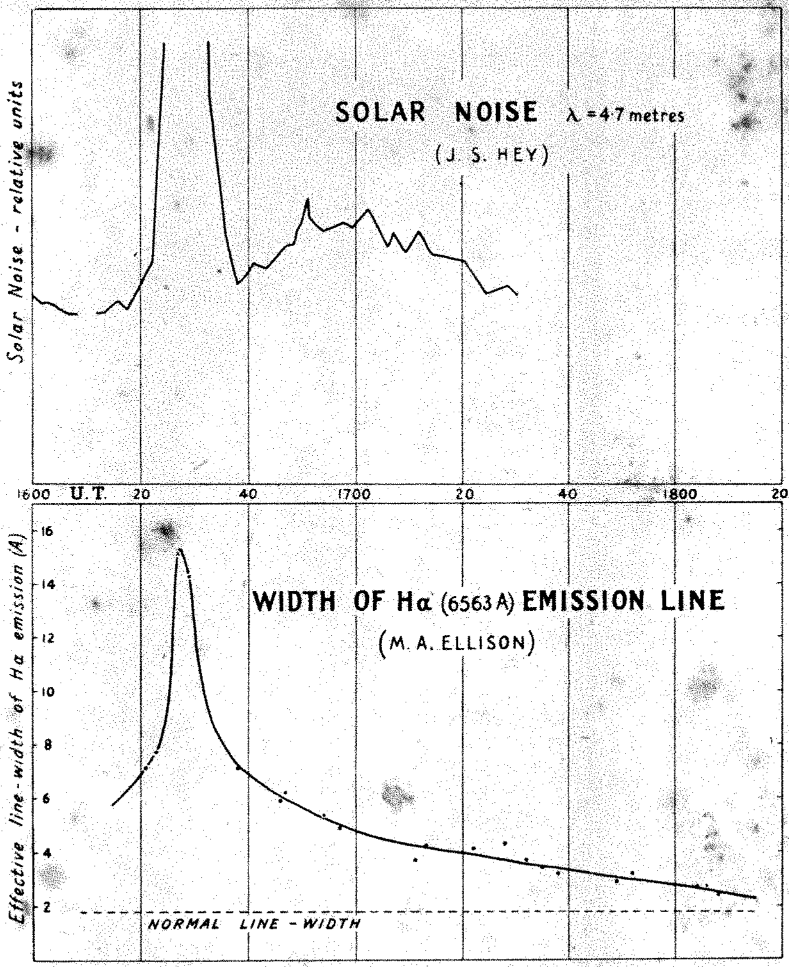

Fig. 2

resonance line of neutral helium at 584 A., though it is still a moot point to what extent these radiations may suffer re-absorption in the chromosphere before emergence. Certainly in the visible range the $H\alpha$ emission line at times shows strong chromospheric absorption superimposed upon the line centre; but it is significant that in this case the wings of the line, which are thought to be broadened by the Stark effect, emerge undiminished in brightness. The degree of this central absorption seems to be indicative of the very variable height at which flares may occur within the solar atmosphere[5].

In addition to monochromatic emissions in discrete wave-lengths, enhancements of the continuous spectrum of flares are to be expected in the ultra-violet. Such a brightening of the continuum in the region of 1000 A. would possibly have its greatest effect in the oxygen ionization of the terrestrial E-layer. A similar brightening of the continuous spectrum has been photographed in the visible region during an intense flare[4], and on other occasions flares have also been rendered visible for a short time in integrated (white) light by this cause.

The absence of Doppler shifts in the spectral lines is an indication that flares are nearly stationary in height, nor have any large horizontal motions been observed relative to other chromospheric features. In this respect they stand in striking contrast to the sunspot prominences (seen as small dark filaments on the disk) the velocities of which are frequently greater than 10 km./sec.

In the radio spectrum, intens emissions in association with flare have been reported by Hey, Parsons and Phillips[8] and by othe workers. These radio bursts, a they have been called, are superimposed upon the more continuous 'radio noise' emissio which is characteristic of th presence on the sun's disk o specially active sunspots exceeding in area about 1,000 millionth of the visible hemisphere: th bursts exceed the level of the continuous emission by a factor o 10–100 times. Both the continuous emission from the spot and the bursts associated wit flares can be detected over band of wave-lengths from 1 t 20 metres, with a maximum intensity usually in the region o 5 metres. It is not clear a present whether this limited rang and 5-metre peak are both determined by the varying transparency of the ionosphere t different wave-lengths, or to wha extent they represent a rea change in spectral intensity wit wave-length. Hey[8] has show that on occasions the nois burst at 4·1 metres wave-lengt lags several minutes behin the observed peak of the H emission.

Ultra-violet Effects

The geophysical effects of flare are derived from two different causes: (A) the wav radiations (mainly ultra-violet) which we have bee discussing, and (B) certain corpuscular emissions to b referred to later. The former give rise to the *simul* *aneous* effects, the latter to *delayed* effects after a interval depending upon the travel-time from sun t earth of the particles concerned. Let us conside first the ultra-violet effects.

(i) *Geomagnetic 'Crochets'*. These characterist perturbations of the magnetic needles have bee known to be associated with specific solar outburs since the classic observation of Carrington an Hodgson of an intense solar flare in white light o September 1, 1859. This was accompanied by synchronous disturbance of the Greenwich magnet traces, having a duration of about one hour and range of +16′ in declination and −110 γ in horizont force. In a recent summary of the Greenwich record Newton[9] has assembled an impressive amount evidence for the synchronous occurrence of 'crochet and intense (3 or 3+) flares. While the 'crochet are confined to the daylight hemisphere of the eart their occurrence is further restricted, for reasons n yet clearly understood, to regions within about 7 of the sub-polar point. The comparisons made wit visual observations show that the 'crochet' distur ance follows very closely in amplitude and duratio the course of the flare development as recorded i $H\alpha$ light. The mechanism of 'crochet' formation

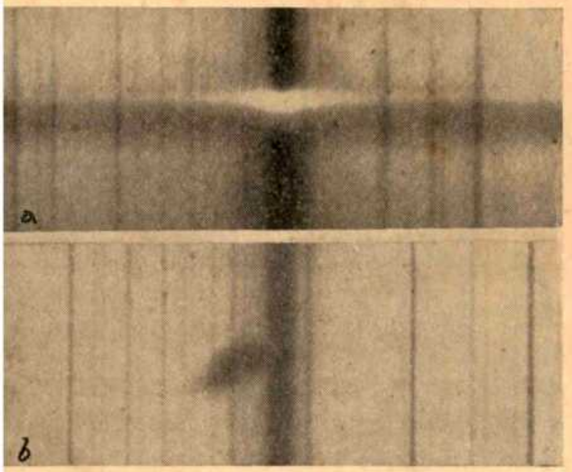

Fig. 3 (*a*). Flare emission line (*Hα*), July 25, 1946 (Sherborne); (*b*) Doppler displacement (140 km./sec.) of surge ejected by a flare (Edinburgh)

not known with certainty; the most favoured hypothesis is that which assumes the sudden movement of a conductor in the earth's magnetic field, such as, for example, the convective motion by heating of an existing or newly formed ionized layer n the ionosphere. In other words, according to McNish[10], the crochet phenomenon is to be regarded as a sudden intensification of the normal diurnal variation of the magnetic elements.

(ii) *Short-wave Radio Fade-out.* Next, in order of discovery, is the so-called Dellinger[11] effect (1935). Suddenly, within the space of a minute or so, short-wave (10–50 metres) channels of communication suffer a partial or complete interruption, at least if any part of them happens to lie in the sunlit hemisphere of the earth, from which we deduce that the cause is a wave- and not a particle-effect. The fade-out is found to be synchronous with the flare and comparable in duration with its visibility in $H\alpha$ light. The immediate cause of the fade-out is the formation of a newly ionized non-reflecting layer at a height of 70–90 km., the cause of which is usually ascribed to he resonance line of hydrogen, Lyman α. This emission line (1215·7 A.) in a flare must have an intensity and a line-width far exceeding those we have recorded in the visible spectrum for $H\alpha$. This in itself would not give rise to atmospheric ionization; but it so happens, as was first noted by Chapman and Price[12], that the resonance line of atomic oxygen has a wave-length of 1217·6 A. The wide wings of $L\alpha$ will certainly overlap this oxygen line for the greater part of the life-time of a flare. Terrestrial oxygen atoms will thus be excited, and if left to hemselves will immediately return to the ground-tate. In the denser atmospheric layers at 70–90 km., however, collisions with other particles will be sufficiently frequent and will supply sufficient energy o bring about ionization of the excited oxygen atoms before they have time to re-radiate.

(iii) *The Long-wave Phase Anomaly.* A new and very sensitive means of measuring the changes in D-layer ionization has recently been perfected by Bracewell and Straker[13], of the Cavendish Laboratory, Cambridge. In these investigations the transmitter *GBR* at Rugby, emitting waves of frequency 16,000 cycles per second (about 19-km. wave-length), is usually employed. Two waves from Rugby are eceived at Cambridge, the ground wave and the sky wave by reflexion from the ionosphere. There is a phase difference between the waves arriving by the two different routes, the value of which shows a characteristic diurnal variation depending upon the changes in effective height of the reflecting layer between day and night. When a solar flare occurs a sudden change of phase is recorded, representing a fall in the effective height of the reflecting layer. An intense flare, for example, may cause a phase change as great as 500°, corresponding to a lowering of the reflecting ceiling by 15 km. The sudden onset is followed by a slower recovery to normal. In Fig. 4 is shown a detailed comparison between such a phase anomaly and an $H\alpha$ line-width curve for a flare (June 7, 1948) measured with the spectrohelioscope at Edinburgh.

Flares of the lowest intensity (1) on the visual scale are found to produce measurable anomalies, and solar physicists welcome this development as a more powerful and reliable means of recording flares during prolonged periods of cloudy weather when spectrohelioscope observations are impossible. In clear weather, also, it may be employed as a warning device to enable workers to train their spectrographs on active solar regions and so to pick up flares which would otherwise pass unobserved. Moreover, it seems very probable that a detailed study of the shapes of the anomalies, by comparison with the line-width observations of $H\alpha$ emission, will decide whether or not it is the $L\alpha$ radiation from hydrogen atoms which is the active agent in disturbing the ionosphere at such times.

Particle Effects

(i) *Geomagnetic Storms.* Maunder (1904) was the first to demonstrate that great magnetic storms (range in $D \geqslant 1°$, H or $V \geqslant 300\,\gamma$) on the earth coincided approximately in time with the passage of large sunspots across the sun's central meridian. More precisely, he found that the storm began, on the average, about 26 hours after the central meridian passage of the sunspot, corresponding to a position of the spot in long. 14° W. The converse of this was not true, that the central meridian passage of every large spot was followed a day later by a magnetic storm. The connexion with sunspot regions was thus established; but the cause of the connexion as well as its delayed action remained obscure. Lindemann (1919) suggested that the agency responsible for the storms consisted of clouds of ionized gas ejected by radiation pressure from the sun. Later, Chapman and Ferraro[14] showed how such storms could be produced and even their detailed characteristics

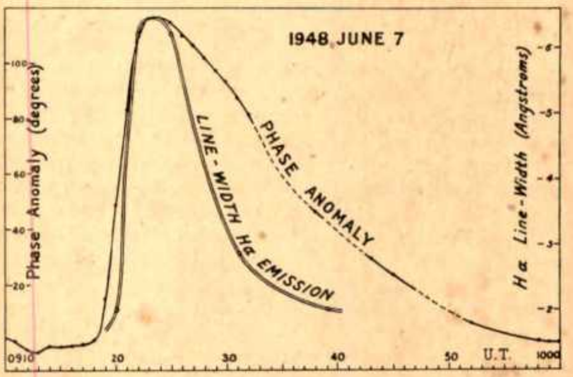

Fig. 4

explained on their theory of neutral ionized streams of corpuscles emitted from limited regions of the solar surface. What were the source points of these corpuscular streams? Were they continuous or intermittent? And why did some large sunspots appear to generate them, others not?

In 1944, Newton[15] completed his comprehensive analysis of the data of association between intense flares and great magnetic storms occurring about one day later. This paper produced an almost overwhelming case in favour of a direct causal connexion between the two phenomena. The time interval (storm begins *minus* flare first observed) given by the data was 25·7 ± 1·5 h.; but the largest of five great storms gave 20·3 ± 0·9 h., and this difference of particle travel-time was considered to be a real effect in view of the probable errors. An examination of the angular distances from the centre of the sun's disk of the flares preceding great storms led to the conclusion that the storm-generating agency failed to reach the earth if the flare was located farther than about 40° from the central meridian.

These facts are consistent with the formation at the time and place of the flare of a single, short-lived blast of corpuscles confined within a cone-shaped beam the vertical angle of which is about 90°. If the earth at the time is suitably placed in its orbit, it will make a 'head-on' collision with the base of this cone as it expands outwards at a speed of about 1,600 km./sec. The Chapman and Ferraro mechanism then comes into play, and the characteristic 'sudden commencement' of the storm traces represents the arrival of the first particles in the polar ionosphere. The aurora borealis and australis are the well-known visible accompaniments of these particle streams. Indeed, the aurora is Nature's great 'advertising sign', announcing that ions and electrons, transporting solar energy, are reaching their destination. What is less commonly realized is that during a spectacular auroral display the major fluctuations of luminous intensity can be closely correlated with the more violent oscillations of magnetic traces.

There still awaits discovery the cause of a class of minor magnetic storms, showing (unlike the great storms) a well-marked 27-day recurrence tendency, corresponding to one synodic solar rotation period. Their magnetic trace characteristics are also different from those of the great storms. A continuously emitted stream of particles radiating from a limited solar region might give rise to such effects as it periodically sweeps across the earth. Wulf and Nicholson[16] have recently produced evidence suggesting that ultra-violet light, emitted from patches of quiescent bright hydrogen on the sun, rather than a corpuscular beam, may be the active agent generating this type of storm. Since the matter is undecided, it focuses attention on the need for much fuller investigation than hitherto of chromospheric and ionospheric phenomena at times of sunspot minimum activity, when these recurrent storms are more easily studied than at other periods in the solar 11-year cycle.

What is the nature of the storm-generating particles and why have they not been detected before arrival on their one-day journey from the sun? Some years ago, Chapman suggested that the streams should be detectable spectroscopically, since they would cause anomalous absorptions in the Fraunhofer spectrum displaced to the violet by Doppler effect. Such absorption in the region of the *H* and *K* lines of calcium has been reported during magnetic storms by Richardson[17] from Mount Wilson and by Brück and Ruttlant[18] from Cambridge. In both instances, however, the magnitude of the observed result is so little greater than the errors inherent in the photometry that further confirmation is needed. At Sherborne and Edinburgh[5] the absorption effect has been sought for close to the $H\alpha$ emission during and shortly after the occurrence of the flare, when, according to Kahn's[19] recent theoretical investigation, the chances of detection are more favourable than later on. A small but definite asymmetry in the emission line has been established as a result of more than five hundred measures relating to ninety-nine different flares. It is found that near the time of peak intensity the blue wing of the emission is less extended than the red wing, suggesting absorption by hydrogen atoms in the 2-quantum state which at this time are in process of accelerating away from the flare region. Hydrogen is, of course, the most abundant element in the chromosphere. Moreover, the action of the Lyman α radiation from the flare will be to increase greatly the population of the 2-quantum state of hydrogen in the vicinity of the flare while it is in operation.

In the search to detect the storm-generating particles another characteristic flare phenomenon has been photographed at Edinburgh[5]. About 80 per cent of intense flares are known to give rise to thin jets of prominence material, consisting in the main of hydrogen and calcium atoms. These filaments are ejected with an initial velocity of about 200 km./sec. at the time of greatest intensity of the $H\alpha$ emission from a point in the chromosphere near the flare but not directly over it. They rise to a maximum height of the order of 100,000 km. before coming to rest and returning along the same (sometimes curved) trajectory. In Fig. 3*b* is shown the spectrum of the $H\alpha$ absorption line of one of these flare surges taken during its ascent near the centre of the sun's disk and exhibiting a Doppler displacement to the violet of 3 A., corresponding to a velocity component of 140 km./sec. in the line of sight. So far, in the many cases observed visually by Newton[20] and the author[21], there has been no evidence that any part of this *surge* material actually leaves the sun.

(ii) *Cosmic Radiation.* Variations in measured cosmic ray intensity associated with intense flares have been reported by Forbush[22], Ehmert[23] and others. In the great flare of July 25, 1946, for example, an increase of 15 per cent in cosmic ray intensity was recorded about *one hour* after the main burst of $H\alpha$ emission. The present rather meagre data do not allow any certain conclusions to be drawn as to whether these observed increases represent genuine emissions of cosmic ray particles from the flare regions, or merely arise from secondary flare effects of terrestrial origin.

Theoretical Approaches

The facts as we now see them present a tremendous challenge to the theoretical astrophysicists. For it is clear that we must study the flare problem no longer in its restricted solar sense, but in its wider application to the stars in general. The sun is a very average star—average in mass, luminosity and spectral type—and it is long odds, therefore, that any phenomenon of this nature which we find occurring to pattern in the solar chromosphere will also be reproduced in the atmospheres of many millions of other stars, appearing with much greater intensity in some and with lesser intensity in others.

Giovanelli, in a valuable theoretical discussion of flare formation[24], bases his electromagnetic ideas upon the development of induced electric fields in the vicinity of sunspots during the periods of most rapid growth and decay of the spot magnetic fields. At critical values of the electric field which he has calculated, he shows that electrons may gain energy from the field more rapidly than it can be dissipated in atomic collisions. Under such conditions, something analogous to a gigantic lightning flash takes place in the sunspot region. It may be said that there is a great deal of observational evidence in support of the mechanism which he proposes, though there are still many detailed aspects which await explanation.

Discussing the origin of the radio-frequency radiation from the galaxy, Unsöld[25] deduces that this must originate in stars of late type which show flare activity like the sun, only on a scale 10^{11} times as great. Assuming that such stars exist—and there are many features of the emission lines of M-type variables which are similar to solar flare spectra—he develops the hypothesis that cosmic radiation as a whole is the smoothed result of high-energy particle emissions from the flare mechanisms which are continuously and extensively active in the atmospheres of these stellar sources.

SCIENTIFIC INSTRUMENTS AND APPARATUS

PHYSICAL SOCIETY'S ANNUAL EXHIBITION

IN his presidential address to the British Association at Brighton in September last, Sir Henry Tizard said, ". . . it is not the general expansion of research n this country that is of first importance for the restoration of its industrial health, and certainly not the expansion of government research, remote from the everyday problems of industry. . . . What is of first importance is to apply what is already known." In general, knowledge in the physical sciences, he remarked, now accumulates much faster than it can possibly be applied to industry. No new discovery, in any field, is likely to have so quick and beneficial an effect on British industry as the application of what is already known.

This point of view finds support in the Annual Exhibition of Scientific Instruments organised by the Physical Society. The thirty-third exhibition of this character was held at the Imperial College of Science and Technology, South Kensington, during April 5–8. It was formally opened by Prof. G. I. Finch, president of the Physical Society and chairman of the Exhibition Committee. On this occasion more than a hundred and fifty firms, research sections of government departments and trade associations were showing examples of recent developments in the design and production of scientific instruments and new techniques applying physical principles. As the president of the Physical Society pointed out, "The object of the Physical Society is to promote the growth and diffusion of a knowledge of Physics, and the Annual Exhibition, with its accompanying discourses and films, is one of the Society's activities directed towards this end".

Unfortunately, owing to structural alterations now proceeding at the Imperial College, it was necessary this year to reduce the space available for the Exhibition by about 30 per cent, which necessitated reducing the number of exhibits by roughly that proportion. An interesting departure from previous exhibition arrangements was to abolish the line of demarcation between "Trade" and "Research" exhibits. The number of visitors attending the Exhibition this year was about the same as last year, reaching a total of about 13,000. As before, the issue of tickets was restricted to avoid overcrowding.

On three occasions during the Exhibition, the film of the "Teleidoscope" or "Liquid Eidophor" was shown. The film demonstrates a recent development in cinema television equipment. The teleidoscope, developed under the direction of the late Prof. F. Fischer at the Federal Technical Highschool, Zurich, employs a novel means of picture production depending on the effects of electro-capillarity. A modulated cathode ray beam scans a raster upon a uniform liquid layer, the so-called 'eidophor', spread upon a revolving glass disk. Each point of the raster takes the form of a minute lens the curvature of which depends on the instantaneous charge impressed by the scanning beam upon the corresponding area of the eidophor liquid. The raster is resolved into a visible image using a Töpler schlieren system. The potential advantage of this system over the conventional cathode ray tube depends on the fact that it constitutes a true light valve, the light output of which is independent of the energy of the cathode ray scanning beam, an advantage which possesses great flexibility. The degree of picture 'storage' achieved by this system can be varied by appropriately adjusting the rate of leakage of the charges on the eidophor in such a way that the raster remains sensibly unchanged for the duration of each frame and is then electrically wiped out by the conductivity of the eidophor.

Three discourses were given during the Exhibition. The first of these, by Dr. J. A. Radcliffe, of the Cavendish Laboratory, Cambridge, was concerned with "Some Problems of Wave Diffraction in the Ionosphere". Simultaneous observations of radio 'fading' at two points indicate that radio waves are returned from the ionosphere by a process of diffractive reflexion as if from a rough surface. The diffraction effects produced by a simple model of this kind can be related to well-known phenomena of optical diffraction. Dr. Radcliffe showed that the methods of calculation are similar to those employed in the analysis of random fluctuations such as occur with radio 'noise'. The fading was shown to be produced by movements of the random irregularities in the ionosphere and is related to their turbulent or regular motions. It was shown how winds in the ionosphere can be measured, and how some of the observed radio effects are similar to well-known optical phenomena.

In the second discourse, Mr. A. J. Philpot, of the British Scientific Instrument Research Association, dealt with "Some Modern Aspects of Scientific Instruments". He directed attention to the fact that three factors have markedly affected the design of scientific instruments in recent years. In the first place, the field of use of instruments has greatly increased and extends to almost every sphere of human activity. The environment of the scientific instrument is no longer exclusively in the laboratory, and instruments of great precision are now to be found in everyday use in workshop and factory. In the second place, the users of instruments are no longer a specialist class, and only a small proportion are scientific workers. In these days of instrumentation, lay users of instruments probably outnumber the scientific users. Lastly, advances in science and the emergence of new branches of science, notably that of electronics, have given to the instrument designer new aids in the achievement of his purposes. Modern scientific instruments incorporate features which reflect these changing circumstances and take advantage of new techniques.

The third discourse, given by Prof. O. R. Frisch, of the Cavendish Laboratory, Cambridge, gave "A Review of the Methods and Instruments used in Energy Measurements on Particles emitted from Atomic Nuclei". A short discussion of the general phenomena of ionization and excitation of atoms, on which the detection of nuclear fragments is based, was followed by a description of ionization chambers, proportional and Geiger–Müller counters, liquid and crystal counters, and scintillation counters, together with a discussion of their respective merits, and of their suitability for energy measurement. Magnetic and electric deflector methods were considered also, in conjunction both with counters and with cloud chambers. Auxiliary equipment such as coincidence circuits, scalers, kick-sorters, etc., were briefly described.

The wide diversity of the exhibits is indicated in the "Handbook of Scientific Instruments and Apparatus 1949", containing more than 270 pages of descriptive matter and some sixty pages of trade advertisements. This handbook, which is well printed and illustrated on high-quality paper, forms not only a guide to the exhibits but also serves, as its title indicates, as a handbook of reference to present British achievements in scientific instrument design and manufacture. A visitor to the Exhibition was impressed not only by the wide diversity and novelty of many exhibits in electronics and atomic physics, for example, but also by the excellence and high quality in the design and construction of the more ordinary, or more familiar, types of scientific instruments. The latter are exemplified by a wide range of electrical measuring instruments, galvanometers, electrical bridges and test sets, resistors, voltage stabilizers, valve oscillators, recorders, colorimeters, densitometers, microscopes, photometers, photocells, spectrometers, ultrasonic oscillators, X-ray equipment and so on. While most of these are based on well-known physical principles, almost all of them embody up-to-date improvements in important details which make them more serviceable and reliable in the laboratory and workshop. In an age of electronics and atom physics, one is apt to overlook, for example, the importance of such an old friend as the laboratory balance; but the aperiodic balance of to-day is remarkable evidence of progress and is proof of the beauty and excellence of British instrument design and craftsmanship. A micro-chemical balance with a load capacity of 20 gm., a sensitivity of 0·001 mgm. (0·1 mgm. swings the pointer 100 scale divisions), and a short period of oscillation is a very fine achievement. The weight-changing mechanism of modern balances is a great improvement on the old method employing tweezers and a box of weights. Other interesting exhibits of a mechanical nature include an apparatus for producing and measuring accelerations of the order of 10^4–10^5 g; the measurement of the mechanical properties (hardness, work-hardening, elasticity and crumbliness) of cheese, these properties being related to the subjective judgment of cheese 'body' by experts; the 'sine' spring, a new mechanical device having a blade spring shaped like a sine curve, the stiffness of which can be varied continuously from positive through zero to negative values.

On the optical side, an interesting exhibit showed a low-power stereoscopic binocular microscope for use by aural surgeons while performing the fenestration operation. The illuminating system is duplicated so there is no risk of a breakdown during an operation. An optical device for metering the size of particles dispersed in a liquid uses a flat beam of light which, after passing through a layer of the dispersion, falls on a photo-cell and deflects a galvanometer. This gives a continuous indication of the extinction coefficient of the suspension at the sampling depth from which the particle-size distribution can be calculated. Two very good types of double-beam infra-red spectrometer were demonstrated, giving a direct record of percentage transmission as a function of wave-length. The Physical Society Optical Group provided a popular exhibit of curiosities in colour vision, demonstrating Benham's top, Bidwell's ghost and other phenomena associated with colour and the eye. Some very fine examples of electron microscopes were demonstrated, giving magnifications of the order 10,000–100,000 times. These beautiful instruments are now robust and simple to manipulate. Lead selenide cells were shown, capable of covering a range up to 5 μ at liquid-air temperature. A very impressive demonstration was staged by the National Physical Laboratory, using the isotopic mercury lamp, presented to the N.P.L. by the National Bureau of Standards, Washington. The lamp is an electrodeless tube containing pure argon at 3-mm. pressure and 3 mgm. of the isotope mercury-198, produced by neutron irradiation of pure gold. The little globules of this mercury isotope could be seen clearly in the tube. The extremely monochromatic quality of the radiation from the tube made it suitable for the direct measurement of end standards up to 40 cm. length. In acoustics, a low-frequency analyser, developed to the requirements of the Royal Aircraft

Establishment, Farnborough, indicated the sound spectrum of engine vibrations over a range 6–4,000 c./sec., covered in six octave bands. The scan for the six-channel bands is arranged to take place in 1/25 sec. A pulsed ultrasonic gauge was also shown which measures the velocity and attenuation of ultrasonic waves in liquids and gases. Ultrasonic cavitation and emulsification phenomena were demonstrated by means of magnetostriction-type oscillators. An interesting feature of the Exhibition was the increasing use of magnetic amplifiers. A number of these were shown in the amplification of D.C. signals, for example, in recording slowly varying temperatures indicated by a thermocouple. In another example the magnetic amplifier was used to operate at audio-frequencies. The germanium triode oscillator and amplifier, or transistor as it is called by the Bell Telephone Laboratories of the United States, was exhibited. It consists of a small block of germanium with two fine rectifier points placed close together on the surface, so that there is a transfer resistance between them. The input impedance is about 200–400 ohms, the output impedance being about 20,000 ohms, and power gains of the order of 20 d.b. can be obtained.

Owing to supply and other difficulties in the use of natural quartz for oscillator and resonator plates in telecommunications, synthetic quartz crystals are being developed. These are grown by a hydrothermal process using a natural quartz plate as a 'seed' crystal. In the atomic and nuclear field, electronic counters for use with Geiger–Müller tubes were shown to be capable of counting-speeds of the order of 10,000 per minute. A very interesting display of nuclear track photomicrographs was on view, the work having been done by Messrs. Kodak, Ltd., for the Atomic Energy Research Establishment at Harwell. Such a high sensitivity has been reached that the plates will record charged particles of very low ionizing power. Prof. O. R. Frisch demonstrated the application of a pulse sorter to the study of the energy distribution of particles resulting from nuclear disintegration. Each pulse causes a small steel ball to be propelled along an inclined plane with an initial speed depending on the size of the pulse. Each ball described a curved path and lands in one of thirty parallel grooves depending on the pulse height. The balls accumulating in the grooves form a histogram of the energy distribution.

These are but a few items selected almost at random from a most impressive display of modern scientific instruments. The Exhibition as a whole reflected a very healthy state of the industry. As in previous years, an exhibitors' meeting was held during the Exhibition to consider possible improvements in the organisation of future exhibitions. An important feature of the Exhibition which must be mentioned was the revival of the craftsmanship competition, arranged for youths in workshops and drawing offices in universities, research laboratories and in industry to submit specimens of their work. Some very fine examples of instrument construction and design were shown. It is to be hoped that the Physical Society will continue to encourage this feature of the Exhibition, as the future of the scientific instrument industry depends on high-quality craftsmanship.

The industry and the world at large owes a debt of gratitude to the Physical Society for the organisation of this valuable exhibition.

A. B. WOOD

OBITUARIES

Dr. Vladimir Tchernavin

DR. VLADIMIR TCHERNAVIN, born in Tsarskoe Selo in 1887, had lived in Great Britain pursuing his researches on fishes since 1934. He was a man willing to sacrifice more for his ideals of liberty and truth than most of us. At the age of twelve, on account of ill-health, he was sent from St. Petersburg to his grandmother at Omsk; all ailments vanished at Omsk, and the boy and his cousin spent long days with the nomadic tribes of the Siberian plains. The freedom and gaiety of the simple lives of these people made a permanent impression on young Tchernavin, which must have been reinforced as he grew to manhood by the liberal ideas that inspired the revolution of 1905. No wonder that after twelve years of service to the Soviet State he was accused in 1930 of "unproletarian psychology". His arrest was one of many that followed the failure of the first five-year plan, and he spent the next two years in a G.P.U. concentration camp.

Tchernavin's training in biology began informally, and at the age of eighteen he accompanied an expedition to western Mongolia as zoological collector. He travelled later as zoologist or fishery investigator in Mongolia, the Caspian region, Tian Shan, Bessarabia and the Far East. His early interest in fishes was centred upon the life-history of salmon, and he obtained his doctorate in ichthyology for work on structural changes in the salmon during its breeding migration.

Under the Soviets, Tchernavin lectured at the Agronomical Institute in Leningrad, and was later employed in administering the great fishery organisations of the Caspian and Murmansk. He spent long periods working under the rigorous conditions of the northern port. During his imprisonment, he was again employed in fishery work, in the organisations run by the G.P.U. His behaviour at this time was designed to gain the confidence of his gaolers, who gradually allowed him more liberty of movement. At last he was able to arrange to be sent on a fishery project to a place where he had arranged to meet his wife and little boy, and with them he escaped over the mountains into Finland. During this journey the experience gained in expeditions to wild places stood him in good stead. In Finland he wrote an account of his arrest and imprisonment, and Mrs. Tchernavin described the escape. These books, entitled "I Speak for the Silent" and "Escape from the Soviets", were translated into several languages.

At the outbreak of war in 1914, Tchernavin had been on holiday in London. He had hurried to Russia for mobilization, but retained such a favourable impression of London that after his escape it was here that he determined to settle. This he was enabled to do by the Academic Assistance Board (later the Society for the Protection of Science and Learning). With a grant from this organisation he returned to his beloved salmon work, perforce neglected for so many years, and published a series of papers on the life-history of salmon, demonstrating the nature of the changes in the skull during the breeding migration and the connexion between the magnitude of the changes and the size of the fish. Some of this had already been published in Russian during 1918–23, in journals unobtainable in Britain; but the whole was done again, with additional material and a more mature approach, and established Tchernavin as a research worker of high standard.

After this, Tchernavin worked for the British Museum (Natural History), and his first assignment was the collection of fishes made by the Titicaca Expedition of 1937. The taxonomic analysis of this rather uninteresting collection was given almost more than its share of meticulous labour by Tchernavin, who had, like all taxonomists, to cope with the shortcomings of his predecessors as well as with the limitations of his material. A museum analysis could scarcely go further, and this work will form a reliable basis for the study of ecological and genetic differentiation of these little fishes whenever someone finds it worth while. Tchernavin did not enjoy this work—nor the failure of the then editor of the Titicaca reports to appreciate it—and he accepted with great enthusiasm a suggestion that he should report on the oceanic fishes brought back by the "Discovery" expeditions. He took first the Stomiatoids, with the intention of studying the inter-relationships of the genera and families; but he became fascinated by the functional morphology of the head of *Chaulodius* and the movements involved in catching and swallowing prey. He soon found that current conceptions of the movements of the parts of the head and the fore part of the trunk in fishes were false or blurred, and he wrote the first account of these movements, both in the large-mouthed ocean predators and in familiar fishes like the salmon and cod, carried as far as morphological analysis may go. The largest of these works, beautifully illustrated by Tchernavin himself, is now in the press for publication as a separate monograph by the Museum.

In October last he learned that his best friend during recent years was fatally ill. He abandoned his work at the Museum the better to care for her, and although his devoted nursing prolonged her life five months beyond medical expectation, he took his own life on March 31, the day following her death. Many weeks previously he had left the notes for this obituary among his papers where some colleague would eventually find them.

ETHELWYNN TREWAVAS

Prof. H. B. Kirk

Two or three years before his retirement, when a bronze plaque and tablet were erected in honour of Harry Borrer Kirk, emeritus professor of biology, Victoria University College, Wellington, New Zealand, the tributes paid by different generations of his colleagues and students showed the profound affection harboured everywhere for that kindly and companionable soul. He was an inspiring friend, of an old-world cultured courtesy, quietly spoken, gently satirical on occasion, subtly humorous, but possessed of a strength of character which could make itself felt to some purpose—respecting his neighbours as he respected himself. He devoted his life to his students, and the effectiveness of his technique was mirrored by the high proportion of biology scholarships and honours won by his students year after year without intermission.

Prof. Kirk was born in England in 1859, and went to Auckland, New Zealand, in 1863. His father, Thomas Kirk, the New Zealand botanist, was born in Warwick and educated at Coventry, where, in 1850, he married Sarah Mattocks of that city. Prof. Kirk's elder brother, Thomas William Kirk, became prominent in New Zealand as the founder of the Government biological and horticultural departments; thus those two brothers had a far-reaching influence in pioneering the biological services of the Dominion, the elder in the applied and the younger in the academic field.

As a pupil at the Auckland Grammar School and at Wellington College, Prof. Kirk stood high in classics, modern languages, mathematics and science. There being no university college yet established in Wellington, he graduated as an extra-mural student of the University of New Zealand, and in 1883 secured M.A. with honours in zoology and botany. At that time he was employed in the Education Department, where he rose to be assistant inspector of native schools; during the twenty-four years so occupied, he made full use of his travels to study the biology of the country and to understand humanity in all walks of life. In 1903, when he was appointed to the chair of biology at Victoria College, Wellington, as the first professor, he was well equipped for the magnificent work he was to carry on for forty years. There were no laboratories at the outset, and he commenced work in a single room of a kindergarten school at Thorndon, which was available only at night; but by his efforts there arose from that modest beginning the extensive and modern biology block of Victoria College; he lived to see this erected and to occupy it for some years until failing eyesight but not spirit, put a period to his active career. He retired in 1944, and died at Hamilton on July 15 1948, aged eighty-nine years.

DAVID MILLER

Mr. R. A. Todd

THE death of Mr. R. A. Todd, coming so soon after that of Prof. Walter Garstang, has broken yet another link with those pioneer marine biologists at work at the opening of the present century. He was the eldest son of Mr. and Mrs. H. S. Todd, of Norwich where he was born in 1877; educated at Paston Grammar School, North Walsham, he graduated at the University of Leeds. It was in 1898 that Todd joined the staff of the Plymouth Laboratory of the Marine Biological Association as the director's assistant. The director was E. J. Allen, and the only other member of the scientific staff was Garstang who was naturalist in charge of fishery investigations

In those early days one of the first needs was to build up a knowledge of the marine fauna in the Plymouth neighbourhood, and Todd was well fitted for the purpose. He was an able and enthusiastic naturalist, and his name will always be linked with that of Allen in the reports of their well-known surveys of the Exe and Salcombe estuaries. Independently, Todd published an account of the invertebrate fauna of the bays between the Start and Exmouth, and to this day the "Plymouth Marine Fauna" is liberally sprinkled with his initials recording observations on many invertebrates.

In 1902 Todd was transferred to the laboratory at Lowestoft to assist in the international investigations in the North Sea which the Association was undertaking on behalf of the British Government. Here his faunistic knowledge proved invaluable and enabled him to produce his reports on the food of fishes which form the basis of our present knowledge. In 1910 the Lowestoft laboratory was transferred under the Board of Agriculture and Fisheries, and Todd remained there until 1912, when he joined the Fisheries Department as an inspector. In 1920 he was appointed a district fishery officer and returned to Plymouth and the south-west. In this work his scientific experience of the fishing industry and its methods, and his knowledge of the habits of fishes, made him a valuable adviser. He retired from service in 1937, but was temporarily re-employed from the outbreak of war until the beginning of 1944.

Todd had great charm, and will be especially remembered as a kind friend by members of a younger generation on the staff of the Plymouth Laboratory whom he and his wife made so welcome at their home in Elburton, outside Plymouth. Here he was always most anxious to discuss problems of natural history, and to the end he took a lively interest in the work of the Laboratory at which he started his scientific career. He passed away without suffering after a long illness patiently borne, and the sympathy of his many friends will be extended to Mrs. Todd in her bereavement. F. S. RUSSELL

WE regret to announce the following deaths:

Dr. F. S. Locke, formerly reader in physiology at King's College, University of London, on May 5, aged eighty-three.

Count Maurice Maeterlinck, philosopher and naturalist, on May 6, aged eighty-six.

NEWS and VIEWS

University of Nottingham: Installation of the Chancellor

FULL university status was conferred on University College, Nottingham, by the King in Council on July 9, 1948 (see *Nature*, August 14, p. 240); Lord Trent was installed as chancellor of the new University on May 4, 1949. It was a day of magnificent pageantry, and the occasion was described by the great historian, Dr. G. M. Trevelyan, as truly historic. The long procession included representatives of seventeen foreign universities and of eighteen British and Commonwealth universities and university colleges, members of the University Grants Committee, students and staff of the University of Nottingham, the Lord Mayor of Nottingham, and the mayors of neighbouring towns. The vice-chancellor (Mr. B. L. Hallward) opened the meeting and called upon the senior pro-chancellor (the Duke of Portland) and the registrar to lead in the Chancellor. As the Chancellor's procession entered the hall, preceded by the mace-bearer in colourful costume, it was greeted by a fanfare of trumpets. On reaching the platform, the Chancellor was installed by the Duke of Portland, who delivered an address of welcome; he was followed by representatives of other universities. Then Lord Trent received the University's first honorary degree, that of doctor of laws. In returning thanks, Lord Trent described a university "as a seat of learning at which the habit of exact thinking is inculcated and the quest for truth is pursued for its own sake. It is in this sense that our University must be judged as a training ground for future leaders, at every level, of science, and of the arts and professions. The most important factor in industry to-day is the human one. Technical ability is not enough without leadership and vision, and to my mind the best training for these qualities is a course in the humanities."

The remainder of the ceremony consisted in the conferment of honorary degrees on Lord Macmillan, Lord of Appeal, Dr. G. M. Trevelyan, Sir Walter Moberly, chairman of the University Grants Committee, and Mr. E. W. Hives, the eminent engineer who is managing director of Rolls-Royce. The public orator, Prof. W. J. Sprott, introduced the graduands, mixing well-deserved praise with occasional gentle thrusts of humorous raillery. Lord Macmillan, in reply, emphasized the relation of a modern university to commerce and industry. He also referred to the long and fruitful association of Nottingham University College with the University of London, of the Court of which he was for many years chairman. Dr. Trevelyan pointed out that Oxford and Cambridge are nearly at saturation point in numbers. If university expansion on a large scale is to take place, it should take place chiefly in the newer universities. "It must be an inspiring thing to belong to the newest University, so splendidly situated and equipped, in these days when the tide is with you and the future of things academic is so full of value and promise." At a luncheon held at the University before the installation, Sir Walter Moberly, toasting the University, said the auguries for its future were good. It had the support of the authorities and the people not only of the city but of the whole region; it had a home and setting which must be the envy of most universities in Britain and the beauty and dignity of which must be an inspiration to all who entered it; it had already given evidence that it could produce men who had made distinguished contributions to scholarship and who had a high, austere ideal of knowledge.

University of Malaya

THE University of Malaya, created by local legislation enacted in March and April, is the youngest university in the British Commonwealth. Its basis is the fusion of the King Edward VII College of Medicine (1905) and Raffles College (1928), in accordance with the recommendations of the Commission on University Education which, under Sir Alexander Carr-Saunders, visited Malaya in 1947. For some years the University will use the buildings and grounds in Singapore of the two constituent colleges, but hopes soon to begin to erect completely new accommodation on an as yet undeveloped site on the mainland. His Majesty's Government has promised £1,000,000 towards the building fund. The chancellor, Mr. Malcolm Macdonald, has launched an appeal for contributions to an endowment fund. The first vice-chancellor is Dr. G. V. Allen, formerly principal of the College of Medicine. The Faculties of Arts (including social studies), Science and Medicine (including dentistry) will continue the teaching work of the two colleges and will shortly be developed to include departments of Chinese, Malay and Tamil studies. Among the research activities connected with the University are an Ionospheric Research Station, staffed and financed by the United Kingdom National Physical Laboratory, and a Tropical Research Unit, investigating the physiological and psychological effects of a tropical climate, staffed and financed by the Medical Department of the Royal Navy and the Medical Research Council.

Sir George Beilby Memorial Fund: Award to Dr. A. S. C. Lawrence

The administrators of the Sir George Beilby Memorial Fund, representing the Institute of Metals, the Royal Institute of Chemistry and the Society of Chemical Industry, have made an award from the Fund for 1948 of one hundred and fifty guineas to Dr. A. S. C. Lawrence, in recognition of his research work in colloid science with special reference to lubrication and fuel oils. Dr. Lawrence was born in London and educated at Christ's Hospital; in 1920 he became junior lecturer and research assistant at the Royal Institution, first to Sir James Dewar and in 1924 to Sir William Bragg. Later he worked at Cambridge in the Department of Physical Chemistry and also in Prof. E. K. Rideal's newly formed Laboratory of Colloid Science, where he remained until 1942 investigating various aspects of anomalous viscosity, including joint work with Dr. J. Needham on myosin, and on solubilization and related topics. A long investigation was made of soap–oil systems during this period for the Fuel Research Division of the Department of Scientific and Industrial Research. In 1939, researches on coal-in-oil suspensions and on coal tar were carried out for the Fuel Research Station. In 1942, Dr. Lawrence went to the Imperial College of Science and Technology, London, as head of the research team of the joint Admiralty and Ministry of Supply advisory service on lubrication. In 1943 he worked on de-icing ships; later he carried out researches on emulsions of sea water in fuel oil and related problems, including investigations in port areas and in H.M. ships, and eventually became advisor on fuel oil to the Engineer-in-Chief, Admiralty. In 1947 he was appointed senior lecturer in chemistry in the University of Sheffield, a post which he now holds. Dr. Lawrence is the author of numerous papers, mainly dealing with colloids, published in the *Proceedings of the Royal Society* and other journals.

Archæological Discoveries in Moravia

Excavations at Věstonice in South Moravia were resumed in 1948, and Czechoslovak archæologists have already made noteworthy progress in revealing what has been described as a "diluvial Pompeii, preserved not by a downpour of volcanic ash but by the slow accumulation of a blanket of loess". About 30,000 years ago, hunters of mammoths dwelt in settlements along the route of animal migration through the Moravian Gap. These people not only attained skill in the chase, but also possessed considerable artistic talent. There is also evidence that they could count. More objects have recently been added to the collections of worked bones, skulls, utensils and plastic figures that had accumulated from pre-war excavations. The first discovery was that of the remains of four mammoths, each of which is estimated to have weighed eight or ten tons. In what was a human settlement, a plastic model, two inches long, of a woman's head has just been unearthed. It is not so striking as the model, five inches high, known as the Věstonice Venus (*Nature*, **131**, 607; 1933), though it is of great interest on account of its age. A well-preserved baked clay model of a bear has also been discovered as well as a curious whistle, which still functions, made from a mammoth's bone. Photographs of these objects, and an account of them by Dr. Edvard Cenek, was given in a recent issue of the Prague illustrated weekly *Svět v Obrazech*.

Research in Travancore during 1939–46

The University of Travancore Department of Research Report for the Septennium 1939–1946 (pp. ix+594; Trivandrum, 1948) is an admirable illustrated record, as non-technical as possible, of the activities of the Department during the period. It is intended also as a basis of review on which future developments may be planned. The first part briefly reviews the history and organisation of the Department since its institution in 1937. The second part describes the organisation and activities of the Central Research Institute and of its several divisions of applied biology, applied chemistry, marine biology and fisheries, preventive medicine and statistics, and the observatory. The third part deals with the work of the University College, the Institute of Textile Technology and the College of Engineering, while among the appendixes is a list of research publications of the Department for 1939–46. Most of the research in this report deals with the application of science towards the study and utilization of the local crops, industries and resources of Travancore, and the work of the Department covers a very wide field.

The Flamingo

A recent issue of *British Birds* (41, No. 12; December 1948) contains a selection of a remarkable series of photographs of flamingos (*Phœnicopterus ruber*), taken by G. K. Yeates, W. E. Higham, T. W. B. Jeans and H. A. Patrick in the Camargue (Rhone delta) in May 1948. Until recently it has been doubtful whether the Camargue could be regarded as a breeding-place of flamingos; but in June 1948 a large breeding-colony in a remote locality was 'discovered' by Yeates, Higham and Patrick. The locality appears to be the one in which flamingos most frequently breed, or attempt to breed, in the Camargue. When the photographs were taken, a large number of birds, estimated at approximately three thousand pairs, were breeding. In remarkable contrast to their sensitivity in the earlier stages of breeding, when they desert with great readiness, the birds are surprisingly approachable when the young are hatched. The nests are formed of mud scraped up by the birds to form a mound. They are usually made in shallow water and are raised until they are a few inches above water-level, although frequently the water afterwards drops, leaving them high and dry.

Fauna of Australia

An article by A. S. Le Souef in the *Journal of the Society for the Preservation of the Fauna of the Empire* shows how the impact of civilization has altered the fauna of Australia. Over the last 150 years, introduced mammals like the fox, rabbit, hare, cat, pig, black rat and common mouse have spread through the bushlands and are rapidly ousting the native marsupials and terrestrial birds. Already several species of wallabies, rat kangaroos, bandicoots and the marsupial wolf either are, or are on the verge of becoming, extinct. This is particularly so in the open districts of the southern half of the continent, and the Commonwealth Government is now considering the establishment of a fauna park in the vicinity of Canberra. The unique lyre-bird is reported to be holding its own against the fox and the cat; but the striped marsupial wolf may already be extinct. The article also contains an account of the effect of disturbances of the native fauna on general biological relationships.

Two Indian Plant Diseases

THE issue for June 1948 of the *Proceedings of the Indian Academy of Sciences* (**27**, B, No. 6) contains two contributions to the phytopathology of southern India. M. S. Balakrishnan (pp. 161–173) describes a new species of *Pythium* (*P. indicum*), causing a fruit rot of *Hibiscus esculentus*. The fungus has filamentous sporangia, the typical sexual reproduction of *Pythium*, and has a wide host-range, including maize and *Petunia*. K. V. Ramakrishnan (pp. 174–193) has studied isolations of *Piricularia* from four host species —*Oryza sativa*, *Eleusine coracana*, *Setaria italica* and *Digitaria marginata*. No difference in morphology has been found between the four isolates; but their physiology varies somewhat, particularly in the width of host-range, the most favoured sources of carbon and nitrogen, the optimum temperature, and the enzyme status.

Earthquakes during February 1949

SIXTEEN strong earthquakes occurred in the world during February. The strongest and deepest was probably that which occurred on February 2 from a focus some 200 km. deep beneath the Aleutian Islands. This had strength 7½ on the instrumental scale. The next most intense was probably that on February 13 (strength 7) from the Kermedec Islands region. The shock, however, which gave the greatest amplitudes at Durham (500 μ) occurred on February 23, from an epicentre, according to E. Peterschmitt and P. Baltenberger, of Strasbourg, in the Tien-Sehan highlands (latitude 42½° N., longitude 84° E.) and had strength 6¾. The earthquake on February 5 with epicentre near latitude 40° N., longitude 30° E. in Anatolia was felt at Eskishir, Kütahya, Bozüyük and Bursa, and destroyed property in the epicentral region. European earthquakes occurred on February 3, 17 and 19 in the Karnische Alps (felt in Frioul, Italy), in the Basses Alps (Barcelonnette) and south-west of Winterthur, respectively. The earthquake of February 28 occurred in the region of the Sandwich Islands in the South Atlantic Ocean. Movement during the month appears to have been confined to the well-established seismic zones on the earth. Instrumental reports have been received from the central stations of the United States Coast and Geodetic Survey (in co-operation with Science Service and the Jesuit Seismological Association), Strasbourg and Zurich, and from individual stations at De Bilt (Netherlands), Durham, Stuttgart, Toledo and Uccle (Belgium).

New Zealand State Scholarships for Science Graduates

SIX national research scholarships given annually to science graduates by the Government of New Zealand on the recommendation of the Council of Scientific and Industrial Research have been awarded to the following: Mr. J. H. Brown, of Auckland University College, for research in biochemistry with a medical and endocrinological bias, the award being tenable at the Courtauld Institute of Biochemistry, Middlesex Hospital, London; Mr. R. H. Thornton, of the Canterbury Agricultural College, for research in soil microbiological techniques, the award being tenable at Rothamsted Experimental Station, or the Macaulay Institute for Soil Research, Aberdeen, or Department of Agriculture, Canada, whichever is available; Mr. R. N. Brothers, of Auckland University College, for research in sedimentary petrology; Mr. P. G. Harris, of Victoria University College, Wellington, for research in geochemistry; Mr. W. B. Taylor, of Auckland University College, for research in statistics and statistical methods; Mr. C. B. Speedy, of Canterbury College, Christchurch, for research in light-engineering electronics. Each scholarship has a tenure of two years and a value of £250 a year with additional grants for books and university fees. They may be used at approved university colleges in New Zealand and elsewhere; but where facilities are available in New Zealand, every encouragement is given for the courses to be undertaken in the Dominion.

British Scientific Instrument Research Association

ON March 25 the British Scientific Instrument Research Association moved from 26 Russell Square, London, W.C.1 (now required by the owners, the University of London), to new headquarters at 17 Princes Gate, London, S.W.7. The March issue of the *Bulletin* of the Association records that the Russell Square premises were first occupied in November 1918, and that, from that date until October 1946, when the new laboratories at 'Sira', Chislehurst, Kent, were opened, the laboratories and all the activities of the Association were housed at Russell Square. Since the occupation of the new laboratories, the Russell Square premises have been the headquarters of the Association, the home of the Information Department and of the Optical Computing Department, and more recently also the offices of the Scientific Instrument Manufacturers' Association.

Conference on Electron Microscopy at Delft

DURING and since the War, a very active school of electron microscopy has grown up in the Technical University of Delft, under the direction of Dr. J. B. Le Poole. In addition to furthering the applications of the instrument, his work on its technical improvement has been of great importance, and has led to the development of a commercial model by the Philips concern. In view of Dutch interest in this field, the Applied Physics Section of the Netherlands Physical Society is arranging a Conference in Electron Microscopy, which will be held at Delft during July 4–9. Its intention is to bring together specialists from other European countries and from America, to which end an international sponsoring committee has been set up. Both this and the working committee are under the presidency of Prof. H. B. Dorgelo, Technical University, Delft. A programme has been arranged, covering all the main technical aspects and applications of the electron microscope. In each session the opening paper is to be given by an invited speaker, followed by short contributions from others. The chief topics are: image formation and contrast (E. G. Ramberg, Radio Corporation of America), preparation techniques (D. G. Drummond, Shirley Institute, Manchester), resolving power and apparatus (M. E. Haine, A.E.I. Research Laboratories, Aldermaston). The general lecture on microscopes will be given by Dr. Le Poole, and that on applications by Prof. W. T. Astbury. Accommodation is being found in Delft and The Hague by the working committee, and party travel at reduced rates is being arranged from Great Britain. Application forms for accommodation and travel can be obtained from Dr. V. E. Cosslett, Cavendish Laboratory, Cambridge, to whom offers of contributed papers from Britain should also be sent, as early as possible.

Royal Society of South Africa: Officers for 1949

The following have been elected to the Council of the Royal Society of South Africa for 1949: *President*, Dr. J. Jackson; *Honorary General Secretary*, A. J. H. Goodwin; *Honorary Treasurer*, J. G. Rose; *Honorary Editor of Transactions*, Prof. F. Walker; *Honorary Librarian*, Prof. E. Newbery; *Other Members of Council*, Prof. R. S. Adamson, Prof. E. Batson, Prof. B. L. Goodlet, J. J. Hewitt, M. R. Levyns, Dr. B. F. J. Schonland, Prof. C. J. van der Horst, B. de St. J. van der Riet and C. L. Wicht.

Society for General Microbiology: Officers for 1949

At the annual general meeting during April 20–21 of the Society for General Microbiology, the following were elected officers for the coming year: *President*, Prof. J. W. McLeod; *Honorary Treasurer*, Mr. H. J. Bunker; *Honorary Secretaries*, Dr. J. G. Davis (General), 35 Villiers Road, Southall, Middlesex; Dr. W. E. van Heyningen (Meetings), Sir William Dunn School of Pathology, University, Oxford; *Members of Committee*, Dr. L. A. Allen, Dr. C. H. Andrewes, Mr. F. C. Bawden, Dr. S. T. Cowan, Prof. A. W. Downie, Mr. L. D. Galloway, Dr. D. W. Henderson, Dr. R. Lovell, Prof. H. B. Maitland, Dr. P. M. Frances Shattock, Prof. Wilson Smith and Dr. D. D. Woods, with Sir Alexander Fleming, representing the International Association of Microbiologists; *Editorial Board*, Dr. B. C. J. G. Knight and Dr. A. A. Miles (hon. editors), Dr. G. C. Ainsworth, Prof. W. B. Brierley, Dr. T. Gibson, Dr. A. T. R. Mattick, Dr. K. M. Smith, Dr. A. W. Stableforth and Dr. D. D. Woods (associate editors).

Colonial Services Appointments

The following appointments in the Colonial Service have been announced: W. H. Edwards, agricultural officer, Nyasaland; P. Bannister, veterinary officer, Northern Rhodesia; J. L. N. McCulloch, veterinary officer, Gold Coast; M. R. Woulfe, veterinary officer, Tanganyika; C. Ginsberg, veterinary officer, Kenya; J. R. Curry (agricultural officer, Federation of Malaya), senior agricultural officer, Federation of Malaya; A. P. McWilliam (agricultural officer, Trinidad), agricultural officer, Sierra Leone; A. D. Combe (senior geologist, Uganda), assistant director of geological surveys, Uganda; W. Pulfrey (senior geologist, Kenya), chief geologist, Kenya; F. W. Aston (senior veterinary officer, Kenya), deputy director of veterinary services, Gold Coast; P. D. L. Guilbride (veterinary officer, Jamaica), senior veterinary officer, Jamaica; R. A. Hutchinson (veterinary officer, Gold Coast), senior veterinary officer, Gold Coast; J. B. Randall (veterinary officer, Uganda), deputy director of veterinary services, Uganda; G. H. Swynnerton (game ranger, Tanganyika), senior game ranger, Tanganyika.

"Maintenance of Nocturnal Ionization"

Referring to the communication under this title published in *Nature* of March 26, p. 491, N. C. Gerson writes: The material immediately after equation (8) should be replaced by:

The above equation on simple quadrature becomes for the F_2-ionospheric layer, assuming the latter to be an isobaric surface,

$$1/n = (\alpha_0/f) \exp(-ft) + k_1 \exp(-2ft). \qquad (9)$$

This equation is quite distinct from that describing the electron disappearance at the geometric surface of 300 km., namely,

$$1/n = -\{\alpha_0/2f(g + 1/2)\} \exp(-ft) + k_2 \exp(2fgt). \qquad (10)$$

The diagram as printed is correct, and was taken from equation (9) as given above. The legend should be corrected accordingly.

Announcements

The Makdougall–Brisbane Prize for the period 1946–48 has been awarded by the Council of the Royal Society of Edinburgh to Dr. Mowbray Ritchie, Department of Chemistry, University of Edinburgh, for his papers on thermal diffusion published in the Society's *Proceedings* during the period of the award.

Honorary associateships of the Birmingham Central Technical College have been conferred on the following: Sir Arthur Smout, director of Imperial Chemical Industries, Ltd.; Mr. J. J. Gracie, general manager of the General Electric Co., Ltd., Engineering Works, Witton; Mr. J. A. Hunt, general manager of the Hymatic Engineering Co., Ltd.; Mr. F. W. Lawton, Midlands divisional controller, British Electricity Authority; Dr. W. Wilson, manager of the Development Laboratories of the General Electric Co., Ltd., Witton; Dr. H. B. Keene, sometime head of the Department of Mathematics and Physics of the Birmingham Central Technical College; and Mr. Thomas H. Essery, sometime head of the Engineering Design Section of the Birmingham Central Technical College.

On May 17, the bicentenary of the birth on that date in 1749 of Edward Jenner will be marked by the opening of a comprehensive exhibition of Jenner manuscripts and relics at the Wellcome Historical Medical Museum, 28 Portman Square, London, W.1, arranged by Dr. E. Ashworth Underwood, director of the Museum.

Mr. C. G. Conway, of the Mond Nickel Company, known for his work on the development of high-temperature materials, and particularly the Nimonic alloys, has been appointed to the technical staff of Power Jets (Research and Development), Ltd.

The University of California Medical School will be holding a postgraduate course on the medical aspects of nuclear energy at the Medical Center, San Francisco, during August 29–September 3. The chairman of the course will be Dr. Joseph G. Hamilton, director of the Crocker Laboratory, University of California. Full details of the programme, fees, etc., may be obtained from Dr. Stacy R. Mettier, Head of Postgraduate Instruction, Medical Extension, University of California Medical Center, San Francisco 22, California.

The Supplementary List of Titles 1947–1948, issued by the National Research Council of Canada, December 1948, contains only the titles of publications in the series N.R.C. Nos. 1413–1799. It replaces the bi-monthly "Additions to the Publications" that have been issued since the second edition, 1947, of "Publications of the National Research Council of Canada", N.R.C. No. 1638. The bi-monthly "Additions to the Publications" are being issued again from January 1949. Requests for copies of publications listed should be addressed to the National Research Council, Ottawa, Canada.

Concerning New Elementary Particles in Cosmic Rays

An analysis of the composition of cosmic rays at an altitude of 3,250 m. above sea-level (Alagez) which we carried out in 1946 revealed the existence of a noticeable number of particles with masses exceeding that of the meson. This result was obtained by applying a direct method of determining the mass of fast particles, according to their deflexion in a magnetic field and their range as found by absorption experiments. It was shown that almost 10 per cent of the particles of the cosmic rays have masses lying between 250 and 2,000 electron masses. These results were published in Russian in December 1946 [1] and in English in January 1947 [2]. We suggested calling this group of elementary particles 'varytrons', stressing in this way the diversity of masses of the new particles. A month later, in February 1947, in an article in English[3], we presented some evidence which proved that there exist in the cosmic rays positive and negative particles which are heavier than the proton, their masses being as high as 5,000 m_e. All these results were also published in Russian in the *C.R. (Doklady) of the Academy of Sciences of the U.S.S.R.*[4] and in more detail in June 1947 [5].

By using a completely different method, S. J. Nikitin of the same laboratory showed that at least three groups of particles with masses larger than that of those commonly observed could be detected in cosmic rays. By measuring the specific ionization of the particles in argon, Nikitin found that the masses of the new particles group around values of 300–500, 700–1,100, 2,000–3,400 m_e. This investigation was also published in February 1947 [6].

As far back as the summer of 1947, by using a large permanent magnet with field strength of 7,500 gauss, we were able to increase considerably the dispersion of our mass-spectrometer. As a result we were able to resolve in greater detail the mass spectrum of the varytrons, and lines with sufficiently distinct edges could be distinguished; these lines yielded mass values of 200, 250, 330, 500–600, 950, 2,200, 3,400, 8,000 and 20,000 electron masses. These results were published in November 1947 [7].

In *Nature* of October 4, 1947, that is, about ten months after the publication of our first papers, Lattes, Powell and Occhialini[8] announced that they had observed eleven meson tracks in a photographic plate with thick emulsion which, after coming to rest in the plate, disintegrated with the emission of a secondary meson. The ratio of the masses of the primary and secondary mesons was estimated to be 2 : 1. Since they were unable to determine the mass of the primary as well as that of the secondary mesons, this result showed that there are at least two types of mesons, one of which is heavier than the other. Proof of the existence of particles heavier than the meson, however, was presented by us at a considerably earlier date, though no reference was made to this by Lattes, Powell and Occhialini.

We wish to emphasize here that our method is a *direct* method of determination of mass based on the measurement of momentum and range of the particles; moreover, at present it is the only method capable of resolving the complex mass spectrum of the cosmic ray particles. The reliability of our method is seen from the fact that the results published by Lattes, Powell and Occhialini confirm our results.

Lattes, Powell and Occhialini determined the mass of the primary meson ('π-meson') on the assumption that the mass of the meson product equalled 200, which thus leads to the value 400. We should like to point out that in view of the large diversity of varytrons which we have observed, such estimations may lead to erroneous results. Up to the present we have detected mesons with the following masses: 110, 140, 200, 250, 300, 350, 450, 550, 680, 850, 1,000, 1,300, 2,500, 3,800, 8,000 and approximately 25,000 [9]. Since Lattes, Powell and Occhialini could not measure directly the mass of the secondary mesons, they could not distinguish between masses of 140 and 200, and therefore the determination of the mass of the primary meson could not be carried out with any degree of certainty.

A note by Rochester and Butler appeared in *Nature* of December 20, 1947 [10], in which two cloud-chamber photographs were reproduced. On the basis of these photographs the authors concluded that there exist particles which are heavier than the usual meson and which decay spontaneously. The two cases observed by Rochester and Butler are obviously insufficient to permit one to draw such fundamental conclusions. However, in view of our work and the work of Lattes, Powell and Occhialini, such a conclusion seems plausible. Rochester and Butler also do not mention our work, although they express their thanks to Prof. P. M. S. Blackett, who, we had thought, would know of our results.

Finally, in *Nature* of April 10, 1948 [11], Powell and Occhialini again discuss their results obtained with thick photographic emulsions, and again no mention was made of our work.

[11] Powell, C. F., and Occhialini, G. P. S., *Nature*, **161**, 551 (1948).

I first learned of the results of the experiments referred to by Prof. Alichanow and his colleagues in conversations with Dr. A. Rogozinski during a visit to Paris in May 1948. Although I had not, at that time, seen their original papers, I made reference to their work in a lecture which I gave to the French Physical Society during the course of this visit, and in the account of the lecture which appeared afterwards[1]. In later publications, my colleagues and I have referred to Prof. Alichanow's work in so far as this seemed to us to be appropriate[2]. I had hoped that Prof. Alichanow would be able to accept an invitation which we had extended to him to attend the Bristol Symposium on Cosmic Rays in September 1948, and thus to have the benefit of personal discussions with him. These anticipations were not realized, however, and I therefore hope that the explanation given above makes it clear that the failure of my colleagues and I to make any earlier comment on these experiments was not due to any ill-will on our part—or of any desire to ignore the results of our Soviet colleagues—but was a consequence of the difficulties of communication and intercourse between us which exist at the present time.

I believe that similar difficulties are likely to occur in the future unless steps are taken to remedy this situation, and for this purpose a series of fully representative international conferences on cosmic radiation and other subjects would be of great advantage. As a second step, it would be of considerable assistance to physicists in Britain if reliable translations of important papers in Russian could be made available, with a minimum of delay, to interested workers in different fields of study. The responsibility for such translations could, perhaps, be undertaken by one of the learned societies.

In the space of a short letter, I can only comment briefly on the conclusions to which Prof. Alichanow and his colleagues have been led as a result of their experiments. There is now a large body of evidence[3] which establishes the fact that there exist in cosmic radiation two types of mesons, referred to as π-mesons and μ-mesons, of mass 286 ± 3 m_e and 216 ± 4 m_e, and with life-times $\sim 10^{-8}$ sec. and $2{\cdot}2 \times 10^{-6}$ sec., respectively. A π-meson is produced in the collision of a fast nucleon with a nucleus, and a positive particle of this type decays spontaneously to produce a μ-meson and some form of neutral particle.

Apart from the work of Prof. Alichanow and his colleagues, the only evidence for the existence of other types of mesons is derived, so far as I know, from a number of individual photographs, each of which has been interpreted as corresponding to a mode of decay of a meson of greater mass than a π-particle, but no two of which represent the same process. Particles of these types are certainly very rare compared with the π-mesons. The question of the existence of many types of mesons, of sufficient stability to pass through an apparatus of the type employed by Prof. Alichanow and his colleagues without having a high probability of suffering spontaneous decay in flight, is of great importance. The results of their further experiments, made desirable in order that the statistical fluctuations associated with their observations may be substantially reduced, should furnish a decisive answer to this question and will be awaited with great interest.

Tendency Towards Symmetry in Fundamental Physical Structures

THE symmetry properties hitherto used in physics mainly relate to existing geometrical symmetry or formal mathematical equivalence. Less attention has been paid to the one-way *tendency* towards higher symmetry in three-dimensional space, which marks many isolated processes ending in a stable end state. The fact that equilibrium states often possess elements of spatial symmetry or regularity (for example, bubbles, crystals, some atoms, molecules, etc.) may at first sight appear trivial. Yet much is to be gained if geometrical relations such as three-dimensional symmetry and asymmetry can be substituted for physical quantities such as 'structural potential energy', since they are simpler, more general, and closer to what is observed.

No analysis appears to have been made of the systems with equilibrium states possessing special symmetry elements, though the association of stability with symmetry has long been noted. Mayer[1] regarded instability as due to differences, which he called 'forces'. Mallard[2] observed, in relation to crystallization: "Cette tendance vers la symétrie est une des grandes lois de la nature inorganique". Mach[3] said, "there is no reason to be astonished that forms of equilibrium are often symmetrical" (in mechanical and fluid systems). Koehler[4], following Curie[5], suggested more generally that "in an isolated process asymmetries disappear as a constant state is approached". But these ideas have not been clarified or related to recent theories.

The tendency towards three-dimensional symmetry (or minimum asymmetry) in fundamental micro-structures is obscured by the masking effect of thermal disorder, by mathematical methods which emphasize higher formal equivalence and tend to neglect three-dimensional spatial symmetry, and by the fact that when conservation principles and reversible laws are used, the one-way character of the actual phenomenon is ascribed either to initial conditions or to probability effects. Moreover, the mathematical concept of symmetry requires generalization before it can be applied to systems such as nuclei, atoms, and molecules, which display a tendency towards minimal asymmetry, but in general lack perfect symmetry.

Curie[5] formulated two basic principles bearing on the course of physical processes: (i) when certain causes produce certain effects, any elements of symmetry present in the causes must be preserved in the effects; and (ii) effects may nevertheless be more symmetrical than their causes (as in the vanishing of potential or temperature differences, or of structural distortions). Curie's classic paper needs revision to-day, but it contains valuable suggestions.

Two workers have sought to use Curie's second principle by applying it to phase and higher spaces, and showing that the increase of entropy can be regarded as the decrease of a certain type of formal asymmetry. Sellerio[6] showed that in thermal processes "the structural symmetry (suitably defined) of an isolated system tends to increase"; and Renaud[7] enunciated the "generalized Curie principle" that "if a system changes in such a manner that the causes of its evolution are contained in itself, the number of transformations with respect to which it is invariant can only increase".

But Curie can be followed more closely by applying his principle to fundamental structures in three-dimensional space and so developing a *general theory of one way processes*[8], based on the axiom that *in all isolated processes some three-dimensional structural asymmetry decreases.* (A '*one-way*' process is defined as a finite process which, when isolated, never completes a cycle but continually approaches a characteristic end-state.) The asymmetry may vanish and the end-state possess a symmetry element absent in earlier states, or a minimum residual asymmetry may remain, evidenced as a 'force'. One task is to define the three-dimensional symmetry elements, or residual asymmetries, which determine the equilibrium forms of nuclei, atoms, and molecules of various kinds, and here new methods may be required. This has only been done for the 230 crystal types, where group theory can be applied since there are no (mean) residual asymmetries.

This method implies a basic distinction between spatial and temporal relations, and involves a new approach to the theory of fundamental structures. Yet it appears promising for the following reasons.

(*A*) The limitations of the concept of the 'electrically charged point-particle' and of recent particle theories show the need for a more powerful co-ordinating principle, to be found through a closer analysis of the spatial and temporal relations which underlie, and determine the character of, particular physical measurements.

(*B*) The symmetrical (in logical sense) relations of equality, simultaneity, and spatial symmetry, can be defined in terms of the corresponding asymmetrical relations, while the reverse is not possible, the asymmetrical relations being more comprehensive. This suggests that a unified theory should be based on the asymmetrical relations of one-way processes, and that the theory of the symmetrical relations (conservation principles, reversible laws, etc.) will constitute a special branch dealing with limiting cases where the one-way aspect is negligible. The principle of the conservation of energy may have to be replaced by a more general principle of the conservation of asymmetry (for example, including conservation of spin), valid under certain limiting conditions. In any case, the principle of decreasing asymmetry uses only asymmetrical relations and, being therefore of the highest mathematical generality, is suited to serve as the main axiom of a comprehensive physical theory.

(*C*) Just as the mathematics of 'number' provided the basis of the theory of physical quantities, so the more comprehensive mathematics of 'order' (Russellian relation theory) may provide the basis for the more general theory of one-way processes. One branch of this theory is the thermodynamics of non-equilibrium states (rate of entropy production; Prigogine[9], Tolman and Fine[10], and others).

(*D*) As Curie[5] said, "what is necessary [for the presence of a given field] is that certain elements of symmetry should be absent. It is the asymmetry which creates the phenomenon." The absence of a particular three-dimensional symmetry element (in a given frame) is a *necessary*, but not a *sufficient*, condition for the presence of the corresponding physical field (electric, magnetic, etc.). A second task is therefore the formulation of the necessary and sufficient conditions for the presence of the different physical fields, in terms of purely geometrical relations in three-dimensional space, such as structural asymmetries. (Blackett's equation[11] connecting the magnetic field and angular momentum of massive rotating bodies satisfies one necessary condition for the presence of a magnetic field, the absence of 'axial' symmetry or presence of an axial vector; but it is uncertain whether it expresses sufficient conditions.)

Oxide Films Formed on Pure Iron in Concentrated Hydrochloric Acid

WORK is being done in this laboratory on various atmospheric corrosion problems. An apparatus has been set up which measures corrosion-rates by following the oxygen consumption. This apparatus will be described elsewhere. During early stages of this work, an investigation was carried out to find a suitable method for cleaning specimens so that repeated use could be made of them. It was found then that treatment of specimens of enamelling iron ($C = 0{\cdot}01$, $Ni = 0{\cdot}1$, $Cr = 0{\cdot}1$, $Si = 0{\cdot}005$, $Mn = 0{\cdot}14$, trace Cu, Sn, As, Al and Ca) in hot dilute hydrochloric acid gave fairly reproducible corrosion-rates using half-normal sodium chloride solutions in the apparatus. Treatment in cold concentrated hydrochloric acid reduced the corrosion-rate of the specimens to a value approximately one and a half times less than the rate after treatment in the dilute acid.

At the end of a test, specimens were originally cleaned with a bristle brush under running tap water, dried and kept in a desiccator. For any one set of specimens the rate of corrosion of the freshly polished specimens was slow but increased during the next two tests, presumably due to the breakdown of oxide film on the polished surface. During the next three or four tests, however, the rate was fairly constant, but decreased after that. If, however, before each test the specimens were cleaned in hot dilute hydrochloric acid (2 *N* at 75° C.) for 15 min., and washed in running tap water for 10 min., the steady rate was reproduced, and could be reproduced continuously. This steady rate will be referred to as the normal rate. Furthermore, freshly ground specimens treated initially in this manner gave the normal rate at once. If instead of dilute hydrochloric acid, cold concentrated hydrochloric acid was used for cleaning the specimens for periods of two or more minutes, with subsequent washing in cold water, the rate of corrosion was much slower than the normal rate. It was even slower than the rate for freshly ground specimens untreated in acid.

Specimens from several sheets of enamelling iron were treated in a similar manner with concentrated hydrochloric acid, and the same effect was noticed with all of them. However, no retardation of the rate occurred with this treatment in the case of two mild steels (0·7° C. and 0·11° C.) or with a spring steel (0·59° C.).

Enamelling iron specimens after cleaning with hot dilute hydrochloric acid were treated in cold hydrochloric acid solutions of varying concentration. The normal rate was observed after treatment in solutions up to a concentration of five normal. With more concentrated solutions the rate decreased suddenly, and in solutions of concentration greater than seven normal the rate again became steady at the lower value.

An investigation carried out to find the reason for this retardation of the corrosion-rate indicated the possible presence of a protective film. For this reason various specimens were examined by electron diffraction in the Industrial Chemistry Division of the Council for Scientific and Industrial Research, Melbourne (by kind permission of Dr. A. L. G. Rees).

The following results were obtained. Treatment in hot dilute hydrochloric acid: surface almost pure iron; slight indication of oxide forming. Surface freshly polished, untouched by acid: iron and films of Fe_2O_3, H_2O and Fe_3O_4 or γ-Fe_2O_3. Concentrated hydrochloric acid treatment: iron and film of Fe_3O_4 or γ-Fe_2O_3. (Patterns for Fe_3O_4 and γ-Fe_2O_3 are indistinguishable, as both have a cubic structure with lattice constant $a = 8{\cdot}4$ A.)

Oxide films have been found on specimens treated in nitric acid and concentrated sulphuric acid, but there seems to be no account of their formation in hydrochloric acid. Several workers have found effects which they have explained as due to other reasons, but in my opinion some of these may well be due to the formation of an oxide film. Thus the results of Guitton[1], Müller[2] and Yamamoto[3] indicate possibilities of oxide film formation.

Müller's theory of passivity may furnish an explanation of the formation of an oxide film. Considering this case to be analogous to the passivity effects noticed in sulphuric acid, the oxide film formation could be due to the anodic process changing its nature at high current densities. Emission of ferric, instead of ferrous, ions, and also deposition of hydroxyl ions with subsequent formation of an oxide film, would occur. The current density due to local cell formation should be greater in more concentrated solutions. Furthermore, the non-appearance of a passive film for the mild steels and spring steel could be accounted for by the stirring produced by the very rapid hydrogen evolution.

An extension of Müller's passivity work to an investigation of the behaviour of iron electrodes in concentrated solutions of hydrochloric acid should help to elucidate this matter.

Spectra of Iodine and Bromine Solutions

THE assumption of solute-solvent compound formation in certain iodine solutions is largely[1], though not entirely[2], based on spectroscopic evidence, including the violet shift of the visible absorption bond in associated solvents[3], and the appearance of a very strong ultra-violet absorption band at 2970 A. in solutions of iodine in benzene[4]. There are several reasons why the spectroscopic evidence should be interpreted with caution. Solutions of bromine behave spectroscopically in a manner very similar to those of iodine, in that the visible absorption band is displaced to the violet in associated solvents, and in the appearance of a very strong ultra-violet band in the region 2500–2975 A. in several solvents[5]. It has never been stated just why solvation should cause these spectroscopic effects. On the other hand, Bayliss and Rees[6] have shown that the violet shift of the visible absorption band of both iodine and bromine in associated solvents can be explained in terms of the physical effect of the hydrogen-bonded 'cage' of solvent molecules around each solute molecule, and Rees[7] has obtained good quantitative agreement between the calculated and experimental displacements when water is the solvent.

Experimental work now in progress has shown that the ultra-violet band of bromine in benzene has $\varepsilon_{\text{max.}} = 6800$ at 2930 A. and an oscillator strength $f = 0{\cdot}18$ [8], and that the corresponding iodine band has $\varepsilon_{\text{max.}} = 9200$ at 2980 A., with $f = 0{\cdot}23$ [9], the latter result confirming the work of Benesi and Hildebrand[4]. These ultra-violet bands are very strong, and are of the order of magnitude of the (N,V) transitions which occur in gaseous bromine and iodine in the vacuum ultra-violet[10] in the neighbourhood of 1600–1700 A.

On the basis of a simple semi-classical treatment, I have shown recently[11] that, relative to the gas state, an absorption band in solution should be displaced towards the red by an amount (in terms of wave number ν) given by

$$\Delta\nu = (4e^2D/\alpha hc)(1 - 1/n^2), \qquad (1)$$

where α is the polarizability of the solute molecule, n is the refractive index of the solvent in the appropriate spectral region, and D is the dipole strength of the absorption band, which is expressed[10] in terms of experimental data by

$$D = 4{\cdot}0 \times 10^{-20}\, \varepsilon_{\text{max.}}\, \Delta\nu_{1/2}/\nu_{\text{max}}, \qquad (2$$

where $\Delta\nu_{1/2}$ is the 'half-width' of the absorption band. If the strong ultra-violet absorption bands near 2900 A. in iodine or bromine dissolved in benzene are the (N,V) transitions displaced to the red by the physical effect of the solvent, equation (1) accounts for about two-thirds of the observed displacement. The red shift of the visible absorption bands predicted by equation (1) for both bromine and iodine is small (owing to their relative weakness) compared with the observed violet shift, which in this case should be interpreted as the result of the electrostatic red shift superimposed on the violet shift due to the caging effect of the solvent molecules.

It seems clear that, whatever other evidence there may be for solvation in iodine and bromine solutions (for example, the dipole moment data[2]), the spectra can be accounted for almost quantitatively on the basis of the physical properties of the solvents without postulating any special solute-solvent interaction.

Photoconductivity of Naphthalene and Anthracene

Recent studies[1] of the mobility ('metallic' character) of the unsaturation electrons within molecules containing conjugated double-bond systems suggest that solid conjugated compounds should exhibit the phenomenon of photoconductivity, provided that the unsaturation electrons can acquire enough energy to penetrate the potential barriers between adjoining molecules in the crystal lattice. Photoconductivity has, in fact, been observed in proteins[2] and in certain dyes[3]. We have found that both naphthalene and anthracene, when melted and allowed to solidify between two platinum electrodes about 0·5 mm. apart, show weak photoconductivity when exposed *in vacuo* to the unfiltered radiation from a quartz mercury-vapour lamp. With applied voltages between 50 and 360, the photocurrents are detectable with a good galvanometer. They are of the order of magnitude of 10^{-8} amp., and are superimposed on a rather variable dark current. As in the case of dyes[3], the photocurrents are quenched if air is admitted to the system.

In the case of dyes, the onset and decay of photoconductivity require periods of many minutes[3], a fact which we confirmed in our preliminary experiments. With naphthalene and anthracene, the onset and decay when the shutter is opened and closed are more rapid than the period (3 sec.) of the galvanometer. By using calibrated wire screens to reduce the incident light intensity, we have found the currents to be directly proportional to the intensity.

The photoconductivity of dyes obeys Ohm's law approximately[3]; but with naphthalene and anthracene the relation between current and voltage is exponential. Within the range of voltage employed, good straight lines are obtained by plotting the logarithm of the current (i) against the voltage (v), suggesting the relation $i = a \exp bv$. This relation cannot hold down to $v = 0$, and it suggests comparison with the relation $i = a (\exp bv - 1)$ for contacts between metals and semi-conductors[4]. It is not yet possible to say which potential boundary in the system is responsible for the form of the i–v relationship, namely, the boundary between the metal electrode and the organic compound, the inter-crystal boundaries in the molten compound or the inter-molecular boundaries within a single crystal.

The photocurrents are quenched if a fused silica cell containing distilled water is interposed in the path of the light, suggesting that the active radiation is λ 1849 of the mercury spectrum.

Effects of Very Fine Solid Particles on Flame Propagation

Methods of promoting gaseous combustion reactions are usually of both practical and theoretical significance. Some preliminary observations made by us recently on the apparent influence of very fine solid particles on flame propagation may therefore be of interest.

The particles were introduced into the fuel–air mixture by passing the air (or in some cases its nitrogen constituent), before mixing, through an arc struck between metal electrodes. The mixture was then passed into a long 2-in. diameter vertical glass tube for measurements of limits of inflammability according to the 'flow' method used by Burgoyne and Williams-Leir[1]. The temperature of the gas mixture at the point of application of the igniting source was only a few degrees above atmospheric.

In some cases quite a marked widening of the inflammable range was observed when the arc was in operation. Thus, with iron electrodes and all the air passing through the arc, the lower limit (upward propagation) for hydrogen in air was reduced from 4·0 to 3·5 per cent and that of ethylene from 3·4 to 2·7 per cent. Under the conditions of operation the concentration of iron in the ethylene–air limit mixture was approximately 10^{-3} per cent by weight. Electron diffraction patterns indicated that the particles were iron oxide and of the order of 300–500 A. in diameter. Experiments have also been made with methane and with various electrode materials, including carbon. In most, though not in all cases, lower limits are lowered and upper limits raised.

In collaboration with Dr. A. G. Gaydon we have made spectroscopic observations on stationary ethylene–air flames containing particles similarly introduced. The most interesting result is that, with iron electrodes in use, certain Fe lines of high excitation at about 3000 A. occur only in the inner cone of the flame. When copper electrodes are employed, well-marked CN bands are obtained. At present we are studying the chemical effects of the particles on the reactions underlying flame, and consideration is also being given to the physical factors influencing the effects on flame propagation. It would be premature, however, to offer any definite conclusions yet regarding this part of our work.

After we had carried out the preliminary work on limits of inflammability, we realized that some experiments of Lewis and Kreutz[2] on the subject of 'ionization' are probably relevant to our observations. They found a considerable lowering of the ignition temperature of methane–air mixtures the incombustible constituents of which had traversed nickel electrodes across which high-tension sparks were passing. We think it likely that this effect and the effects that we have observed have a common cause.

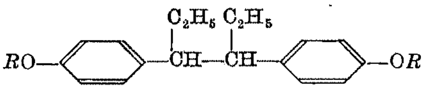
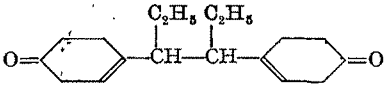
Reduction by Sodium – Ammonia Solutions

REDUCTION of methoxybenzene derivatives by the sodium–ammonia–alcohol reagent followed by acid hydrolysis leads to the formation of a number of hitherto inaccessible unsaturated ketones[1]. The process fails with some compounds because of their insolubility in liquid ammonia, a typical example being hexœstrol dimethyl ether (I, $R = CH_3$). This substance has been treated under a variety of conditions and with admixed solvents, for example, ether or ethylenediamine, but so far without success.



I



II

The observation that alcohols are often readily soluble in ammonia has now led us to replace the methyl ethers of phenols by the 2-hydroxyethyl- or glyceryl-ethers. These ethers are, in fact, more readily soluble in ammonia and are easily prepared by the action of the appropriate chloro-compound on the sodium phenoxide in hot aqueous solution. The ether side-chain is lost during acid hydrolysis, so its nature does not affect the final product. A further advantage with these ethers is that any unreduced material present in the product can be removed because of its relatively higher boiling-point.

Hexœstrol (I, R=H) gives rise to a *bis*(2-hydroxyethyl) ether (I, $R = -CH_2CH_2OH$) which crystallizes as colourless plates from benzene, m.p. 90–91° (found: C, 73·4; H, 7·9; $C_{22}H_{30}O_4$ requires C, 73·7; H, 8·4 per cent). This is readily reduced and gives after acid hydrolysis 3:4-di(4′-ketocyclohex-1′-enyl)hexane (II), which forms clusters of prisms from ether–light petroleum, m.p. 131–132° (shrinks 120°) (found: C, 78·6; H, 9·9; $C_{18}H_{26}O_2$ requires C, 78·5; H, 9·5 per cent) (bis-semicarbazone m.p. 242° (decomp.)). The formulation of (II) as the βγ-unsaturated ketone rests on the lack of an absorption maximum in the region 2200–2700 A. It is being tested for possible sex-hormone activity.

The reduction of other phenols, including œstrone, and the synthesis of some natural products are being carried out.

Re-arrangement of Acyldiazoethanes

THE appearance of a paper by Wilds and Meade[1] on this topic renders an account of our own experiments desirable, more especially as we have in various respects carried the matter further than the American workers.

The statement (without experimental details) by Eistert[2] that *p*-nitrobenzoyldiazoethane is convertible in hot aniline to α-(4-nitrophenyl)propionanilide has been experimentally confirmed, most satisfactorily by addition of the diazo-compound to the base at 100–105°. Similarly, anilides of *iso*butyric, α-phenyl and α-(4-methoxyphenyl)-propionic acids, and the dianilide of αα′-dimethylsuberic acid were prepared.

While these results are doubtless to be attributed to initial thermal decomposition of the diazo-compound to a ketene[3], followed by reaction with aniline, it is incorrect to assume[4] that this is also the mechanism of the Wolff re-arrangement as usually performed. This has been recognized by Eistert[5]; but we are also unable to accept his views in regard to the latter reaction; for successive additions to an ethanolic solution of benzoyl (or 4-methoxybenzoyl)-diazoethane (1 mol.) at 70° of an ethanolic solution of aniline (1 mol.) and of 10 per cent aqueous silver nitrate solution yielded β-anilinopropiophenone (or its 4-methoxy-derivative):

$$PhCOCMe = N = N \rightarrow PhCOCH_2CH_2NHPh + N_2.$$

This clearly arises from addition of aniline to benzoylethylene (I), the formation of which recalls that of olefines together with primary and secondary alcohols by decomposition of the diazonium compounds resulting from the action of nitrous acid on primary aliphatic amines[7]. We thus conclude that the course of the reaction is to be expressed as follows, the base functioning alternately as acceptor and donor of proton:

$$\begin{array}{l} PhCO.CMe{=}N{=}N \rightarrow [PhCO.CHMe.N{\equiv}N]^{\cdot} + PhNH_2 \\ \quad + PhNH_3^{\cdot}\ , \qquad\qquad \downarrow \qquad\qquad (Ag) \\ \qquad\qquad\qquad PhCO.CH{=}CH_2 + PhNH_3^{\cdot} + N_2 \\ \qquad\qquad\qquad\qquad\quad (I) \end{array}$$

Similarly, the normal Wolff re-arrangement corresponds to the Wagner–Meerwein re-arrangement by which the formation of secondary alcohols occurs. Thus, in the case of benzoyldiazomethane and ammonia, we have

$$\begin{array}{l} PhCOCH{=}N{=}N + NH_4^{\cdot} \quad \rightarrow \quad [PhCO.CH_2.N{\equiv}N]^{\cdot} \\ \qquad\qquad\qquad\qquad\qquad\qquad + NH_3 \\ \qquad\qquad\qquad\qquad\quad (A) \downarrow \quad NH_3 \\ \qquad\qquad\qquad NH_2CO.CH_2.Ph + NH_4^{\cdot} + N_2. \end{array}$$

Evidently, also, when the opportunity is available for both types of charge, the former occurs in preference to the latter.

The preparation, for the reactions just discussed, of acyldiazoalkanes from acid chloride and diazoalkane requires an excess of the latter to react with the hydrogen chloride formed[8]. Whereas, however, in the use of diazomethane any adequate excess may be employed, either this, in the case of diazoethane and, it may be presumed, its homologues, should be limited to that theoretically requisite, or, if excess be employed, the duration of the reaction should be limited; for *p*-nitrobenzoyldiazoethane, m.p. 112°, reacts with diazoethane at the ordinary temperature in ethereal solution to yield a product

$$\begin{array}{l} NO_2 . C_6H_4 . CO . CMe = N = N + MeCH = N = N \\ \rightarrow NO_2 . C_6H_4 . CO . C(Me) = N - N = CHMe \quad (II) \end{array}$$

characterized as the ketazine (II) by conversion into acetaldehyde, hydrazine and acetyl-*p*-nitrobenzoyl on hydrolysis with hot dilute sulphuric acid. This product is naturally also formed in the preparation of *p*-nitrobenzoyldiazoethane unless the precautions just outlined are observed. Similarly, nitrobenzoyldiazomethane and diazoethane furnish the azine $NO_2.C_6H_4COCH=N-N=CHMe$ (III), but the anionoid reactivity of diazomethane is inadequate to enable it to participate in this type of reaction with the cationoid nitrogen atom[8] of acyldiazoalkanes. While, however, the reactivity of this latter is doubtless enhanced by the acyl group, the formation of azine in this manner is by no means unique. The conversion of diazo-*iso*propane into $Me_2C=N-N=CMe_2$ at the ordinary temperature[9] and the numerous other examples of ketazine formation cited by Staudinger and Kupfer[10] are clearly to be regarded from this aspect, which has hitherto usually been neglected owing to the almost exclusive attention accorded to the anionoid reactivity of aliphatic diazo-compounds. But the conversion by alkali of diazoacetamide into a triazolone[11] is an example of the cationoid reactivity in question, while that of diazoacetic ester into a dihydrotetrazine dicarboxylic acid[12], as well as the classical synthesis of pyrazolines[13], also involves cationoid as well as anionoid reactivity of diazo-compounds.

The ketazine (III) does not represent the limit of the reaction between *p*-nitrobenzoyldiazomethane and diazoethane, for if excess of the latter be employed, a compound $C_{14}H_{17}O_3N_3$ (IV), m.p. 134–135°, is formed, with evolution of a corresponding volume of nitrogen. The nature of this product is not completely established; but on treatment with dilute sulphuric acid it readily yielded acetaldehyde, together with a compound, m.p. 196–197° (also obtainable by gradual addition of hydrochloric acid (2*N*) to a solution of (IV) in dioxan at the ordinary temperature), and another, m.p. 175–176° (also obtainable by gradual addition of ethanolic hydrazine hydrate to an ethanolic suspension of III at the ordinary temperature). In view of these results, ketazine (II) would also be expected to react with diazoethane, and, in fact, does so, though much more slowly than (III). It also undergoes gradual internal condensation to a compound $C_{11}H_9O_2N_3$, m.p. 158–159°, in boiling ethanolic solution.

Benzoyl- and 4-methoxybenzoyldiazoethanes react much more slowly than the 4-nitro-analogue with diazoethane; but evidence of ketazine formation in these cases also has been derived from hydrolytic experiments.

Organised Structure in Soap Solutions

My simple picture, fully described elsewhere[1–3], of the aggregates in the clear mobile solutions of paraffin-chain salts is that they are essentially liquid in nature and spherical in form. The discovery[4], by X-ray diffraction, of a characteristic long spacing, decreasing with increase of concentration, appeared to favour a different picture—that of a lamellar micelle in which the chains lay parallel to one another and the outer faces of arrayed ionic groups were separated by a definite thickness of water. One of the protagonists of the lamellar micelle has recently[5] come to modify his picture considerably, and his collaborator[6] to consider that the X-ray data can be explained by the spherical micelle.

There are two difficulties about the lamellar micelle explanation of the X-ray spacings. One, recently raised by Bernal[7], is that in order to account for all the water, the lamellæ must be assumed to be separated laterally by a greater depth of water than that held between the ionic faces. The opposite difficulty was raised by Harkins[8]. When oil is dissolved in the soap micelles, the increase of long spacing is much *greater* than is directly accounted for by the additional volume inside the micelle.

The characteristic long spacing should be considered as a regular distance between geometrically similar groups of diffracting atoms. These need not be planes. They may be spheres regularly spaced, as in the transparent emulsion studied by Schulman and Riley[9].

There are good reasons[3] for believing the micelles to be of closely constant size in any one solution and to vary but little with the concentration. The constancy of spacing demonstrated in concentrated solutions is simply the result of a coulombic packing effect. The micelles are highly mutually repulsive and will therefore tend to array themselves so that their shortest distances of separation are as great as possible, that is, in a closely packed tetrahedron assembly. If the spheres are of radius r and together occupy a fraction φ of the total volume, then their shortest distance d of separation in this arrangement will be given by

$$d = \left(\frac{8\pi}{3\sqrt{2}}\right)^{1/3} . \varphi^{-1/3} . r.$$

We will apply this equation to the data of Harkins for potassium laurate and of Stauff[10] for sodium tetradecyl sulphate. To a sufficient degree of accuracy, we can take the mean density of the micelles equal to 1, and thus identify weight and volume fractions. We will calculate r from observed values of d.

Potassium laurate			Sodium tetradecyl sulphate		
Wt. %	d (obs.)	r (calc.)	Wt. %	d (obs.)	r (calc.)
9·1	57·0 A.	14·2 A.	15·1	60–65 A.	17·7–19·1 A.
12·1	56·3	15·4	40·0	55·0	22·3
16·7	51·3	15·6	60·0	48·2	22·5
25·0	47·1	16·4	80·0	42·4	21·7
33·3	44·1	17·0			
41·1	37·1	15·2			

The lengths of the fully extended chains are about 13·7 and 18·9 A. The calculated values are consistent with the sphere radius being, as expected, a little greater than this length[3].

What of the effect of dissolved oil? In a limited region in the centre of the micelle, the oil will probably be the sole component[11]. The radius of the micelle will thus be disproportionately increased, and a disproportionate increase of d will result directly from that of r.

Paper Partition Chromatography of Riboflavine Decomposition Products

THE photolysis of riboflavine has always been considered[1] to be a complex process, but as a rule only the final products, lumichrome (6 : 7 dimethyl alloxazine) and lumiflavine (6 : 7 : 9 trimethyl *iso*alloxazine), have been isolated.

Using Crammer's[2] method and subjecting irradiated samples of riboflavine solution to chromatography, we were able to demonstrate several distinct spots with a very bright fluorescence in ultra-violet light. For the runs, either Whatman No. 1 or Schleicher–Schüll No. 237 filter paper and either the descending or ascending arrangement[3] was used with practically the same results. The ascending arrangement showed more irregularities of flow. 0·08–2·5 μgm. of riboflavine gave satisfactory spots, smaller samples giving too faint a spot and larger ones causing some tailing between the start and position R_F 0·35. Fluorescence was observed in filtered ultra-violet light (Phillora WPH—125 W.). The fluorescence was strong enough to allow the assessment of the fluorescence emission maxima of some spots when irradiating the chromatograms by ultra-violet light and observing the spectrum by means of a Hilger prism ; there was some difficulty due to the weak white fluorescence of the paper background. Good separation was observed using the upper layers of mixtures of butanol, acetic acid, and water (4 : 1 : 5) or butanol, pyridine and water (3 : 4 : 7) as the mobile phase.

Riboflavine was identified by comparing with a carefully prepared fresh solution of riboflavine in sodium salicylate (our R_F was higher than that reported by Crammer[2], who found 0·3 in butanol–acetic acid–water). Lumichrome was compared with a sample prepared according to Karrer *et al.*[4]. Its spot interferes with that of the salicylate in butanol–pyridine–water. Several weaker unidentified spots with R_F less than that of riboflavine in butanol–acetic acid–water were observed, the most constant of them (B) having R_F 0·3. The possibility that some of the spots are due to more than one substance cannot be excluded until a check by two-dimensional chromatograms is made.

The stability of the substances during chromatography in darkness was tested using the two-dimensional principle, but developing with the same solvent pair (butanol–acetic acid) for the first as well as for the second run. The spots then occupied the diagonal position. As would be expected[5], sodium hydroxide solution changes the fluorescence of lumichrome spot to yellow and extinguishes those of the other photolytic products.

After exposure to hydrogen peroxide in alkaline solution, the spots of riboflavine and lumichrome were accompanied by three more spots, two with blue and one with orange fluorescence, although riboflavine has generally been reported to be stable to oxidizing agents[1]. Heating in alkali resulted in the disappearance of the other spots and the appearance of a new one with a bright ultramarine fluorescence and R_F 0·51 in butanol–acetic acid. The results are summarized in the accompanying table.

Spot due to		R_F in BuAc	R_F in BuPy	Colour	Fluorescence in u.-v. light
after illumination	(A) not identified (adsorbate on paper ?)	0·0	0·0	yellow	yellow
	(B) not identified	0·30			yellow
	(C) riboflavine	0·37	0·57	yellow	yellow
	(D) lumiflavine ?	0·49	0·54	yellow	yellow
	(E) lumichrome	0·70	0·76	φ	greenish-blue (max. 490 mμ)
Salicylate (when used as hydrotropic agent)		0·92	0·76	φ or pink	blue
Action of hydrogen peroxide on alkaline solution of riboflavine		0·08 0·22	0·23 0·52		blue
		0·16	0·37		orange

Commercial injection solutions were analysed by this method, which seems suitable for following the influence of various conditions on the rate and nature of photolysis. The nature and conditions of formation of the unidentified substance B are under investigation.

A Source of Error in the Colorimetric Estimation of Uranium

FOR several years I have obtained consistent results with the hydrogen peroxide method[1] for the estimation of uranium, the intensity of the peruranate colour being measured with a Pulfrich photometer with filter S.43 (effective filter gravity, 434 mμ). In the hope of achieving greater accuracy and reproducibility, a modern type of spectrophotometer was recently substituted for the visual photometer; the colours being measured at 360 mμ (where the extinction for a given uranium content is nearly three times greater than at 434 mμ). It was found, however, that results were frequently low by as much as 30 per cent, although the same solutions gave the correct result when the absorption was measured with the Pulfrich photometer.

The source of error was eventually traced to the presence of sodium bicarbonate, which is formed in varying amounts when the acid solutions from ether extractions are treated with an excess of sodium carbonate, prior to the addition of hydrogen peroxide. A study of transmission curves showed that addition of bicarbonate caused a considerable decrease in the absorption of solutions in the near ultra-violet (350–400 mμ); but the effect became less marked at longer wave-lengths and disappeared entirely in the region 440–450 mμ. The reason for consistency of results with the Pulfrich photometer thus becomes apparent, and no error will occur using a spectrophotometer if readings are made at 440–450 mμ; but certain precautions must be taken if it is desired to take advantage of the greater sensitivity obtained when measurements are made at lower wave-lengths.

Since the magnitude of the error varies with the amount of bicarbonate as well as with the concentration of sodium carbonate, a correction is difficult to apply, and it is necessary instead to ensure that no appreciable quantities of bicarbonate are present. This cannot be conveniently done by boiling the solutions, since the presence of excess sodium carbonate causes a marked decrease in the rate of decomposition of bicarbonate, and appreciable quantities of the latter may persist in solution after boiling for more than an hour. The most reliable technique is to avoid the formation of bicarbonate altogether by neutralizing the acid solutions containing uranium with sodium hydroxide; the neutral solutions are then treated with sodium carbonate and the colour developed as usual with hydrogen peroxide.

Further details of experiments and discussion of results will be published elsewhere.

Insecticidal Power and Microscopical Structure of Residual Films of Phenyl-*iso*nitrile and Benzene Hexachloride

In the fight against pistachio nutworm (*Eurytoma pistaciæ*, Anagnos) and pistachio tree leafhopper (*Idiocerus pistaciæ*), we made use of a new insecticide, the basis of which is phenyl-*iso*nitrile. At first it was mixed with nicotine and lead arsenate; later, instead of nicotine and lead arsenate, we added benzene hexachloride. This preparation proved to be promising, owing to the fact that the one constituent—phenyl-*iso*nitrile—kills the insects and at the same time repels them, while the other constituent—benzene hexachloride—not only kills them but also causes the preparation to remain active for a much longer period. This preparation is used in the form of a water-suspension which is sprinkled on the trees diluted with water.

A. J. Musgrave[1] found that residual films of a sample of technical grade benzene hexachloride prepared on glass plates from chloroform solutions showed a stronger insecticidal power than other samples of different manufacture. A microscopical examination carried out by him showed that the film was present in the form of discrete globules. He suggests that high toxicity may be associated with traces of chloroform retained by the film.

We prepared several residual films, on glass plates, of benzene hexachloride as well as of mixtures of benzene hexachloride and phenyl-*iso*nitrile, and we tested them on a species of Myrmicine ant which shows almost the same resistance to insecticides as does *Eurytoma pistaciæ*.

We find that the toxicity does not depend on the organic solvent—chloroform, benzene, alcohol, kerosene oil—from which the film is prepared, but it is in direct proportion to the capacity of the insecticide to adhere on the insect. Comparative tests carried out on glass plates dusted with these insecticides in the form of dry dust containing inert matter showed that the death of the insect occurs more quickly—in about half the time—than when the films were prepared from solutions of the insecticides in organic solvents, in which case the film is better retained on the plate. The quantity of the insecticide used in both cases was the same.

Furthermore, films prepared from solutions of the insecticides killed the insects more quickly when some traces of the organic solvent could be retained in any way by the film. It is justifiable to say that this is due to the greater adhesion of this form of film to the insects. Pure vapours of organic solvents do not seem to cause death of the insects but only a transitory unconsciousness.

A similar effect happens in the case observed by Musgrave. The insect *Dermestes maculatus* Deg., walking on the film, which was present in the form of discrete globules containing traces of chloroform, caused crystallization of the benzene hexachloride, but at the same time owing to the presence of traces of the solvent the insecticide adhered better to the insect. Another fact which must be taken into consideration is that the vapour pressure of the insecticide in the form of discrete globules is greater than that in any other form, as then the insecticide is in the condition of a supersaturated solution; it is known that benzene hexachloride acts as a fumigant as well as a stomach and contact poison.

In general, benzene hexachloride as well as mixtures of benzene hexachloride and phenyl-*iso*nitrile form residual films of greater toxicity when the films are prepared from solutions with organic solvents, instead of water-suspensions of a wettable form of the insecticides (the insecticide contains inert matter with a wetting agent). Unfortunately, most organic solvents 'burn' the plants. The mixture of benzene hexachloride and phenyl-*iso*nitrile had a higher toxicity than either benzene hexachloride or phenyl-*iso*nitrile alone.

The experiments are being continued.

A Saprophytic Liverwort

The saprophytic liverwort described in this communication was found by Mr. M. V. Brian, of the Department of Zoology in this University, early in December 1948, while investigating an ant's nest in a wood near Cardross, Dumbartonshire. The first specimens found and brought into the Botany Department were white, fleshy, irregularly lobed bodies which were provisionally identified as the thalli of a liverwort. A little later, Mr. Brian found further material, which, since it bore young sporogonia, could be identified as a species of *Aneura*, or, at any rate, as being closely related to that genus.

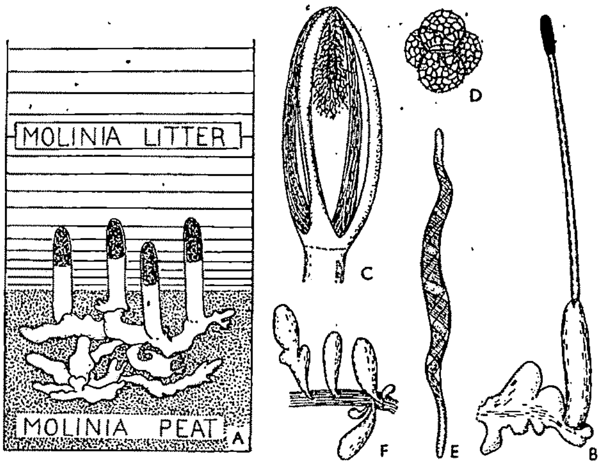

Fig. 1. *A*, Diagram showing plants *in situ*, with young sporogonia (× 0·8); *B*, thallus, collected in the field in February, bearing a ripe sporogonium (× 1); *C*, dehisced capsule (× 7); *D*, spore tetrad (× 220); *E*, elater (× 220); *F*, young plants growing on a decayed fragment of *Molinia* leaf (× 1·2)

Since then, Dr. Bond and I have examined the plant in the field, and a fuller investigation has been started since its completely saprophytic habit is of considerable interest. The occurrence of a similar saprophytic liverwort in France was reported in 1919 by Denis[1]; but, apart from this brief account, referred to by Rayner[2] and by Nicolas[3], I know of no further reference in the literature.

So far, the plant has only been found in a very restricted area on the site of a felled wood, now colonized by young birch. In this particular area the ground vegetation is dominated by *Molinia cœrulea*. The liverwort, fairly abundant in this small area, is found embedded at varying depths ($\frac{1}{4}$–3 in.) in the black, nearly amorphous peat formed between the tussocks of *Molinia*. The *p*H of this peat has been determined by Dr. Bond as being 3·9. At this time of the year, the *Molinia* peat is overlain by a considerable depth of litter in various stages of decay, formed mainly by the deciduous *Molinia* leaves, but including also birch leaves, shoots of *Polytrichum*, and other constituents of the flora.

The position of the liverwort in relation to the peat and overlying litter is shown in Fig. 1,*A*. The thallus is white, fleshy in texture, and much branched and lobed, giving an almost coralloid appearance. Sectioning reveals the presence of coils of septate fungal hyphæ in the lower cells of the thallus, and hyphæ are also present in many of the rhizoids (Fig. 2,*D*). Many of the cells present an appearance similar to that shown by the 'digesting cells' of the root of *Neottia*, the fungus being in a 'clumped' condition. Above the fungal zone the cells of the thallus contain abundant compound starch grains. It may be noted here that Rayner (*loc. cit.*) figured a *Rhizoctonia* type of fungus in the thallus of *Aneura pinguis*.

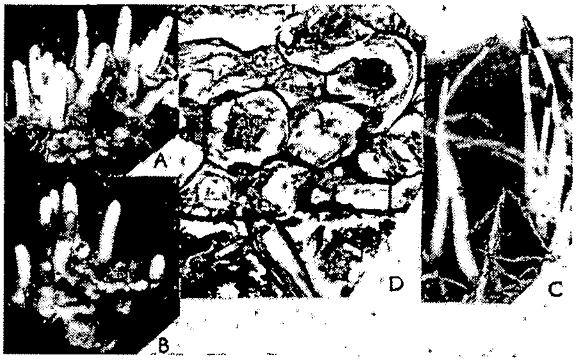

Fig. 2. *A*, Block of *Molinia* peat dissected at its edge to show embedded thalli bearing young sporogonia (× 1); *B*, thallus with young sporogonia showing through the translucent calyptra (× 1); *C*, ripe sporogonia, with one on the left showing the method of dehiscence, borne on plants grown in an incubator and not covered by litter (× 1); *D*, tangential longitudinal section showing hyphæ in thallus cells and a rhizoid (× 150)

The sporogonia appear to be similar in origin and structure to those of the genus *Aneura* and need not be fully described here. Fig. 1,*B–E*, will sufficiently indicate the characters of the capsules, spores and elaters. Fungal hyphæ have not been detected in any part of the sporogonium. The distribution of the sexual branches has not yet been fully determined.

The dehiscence mechanism of the capsule differs from that described for the genus *Aneura*. The capsule wall (similar in construction to that of *Aneura pinguis*) splits into four valves which, however, remain coherent at their tips. The distal elaterophore remains as an undivided, club-shaped mass of tissue hanging down into the capsule. As the longitudinal slits appear and widen, the mass of spores and elaters within enlarges and emerges as a reddish-brown mass. The spores are slowly dispersed and the capsule is finally emptied, leaving it in the condition shown in Fig. 1,*C* and Fig. 2,*C*. Dehiscence has not been observed in the field; but it must frequently, if not always, take place in a confined space in the overlying litter, and it is possible to think of the method of dehiscence as being related to this fact. Mention may be made, however, of the fact that comparable modes of dehiscence have been described in *Pallavicinia* and *Moerckia*.

Young plants (from 1 mm. in length upwards) have also been found (Fig. 1,*F*). They occur in clusters on decaying roots and *Molinia* leaf fragments at varying depths in the litter and peat, the clustered condition probably being the result of a restricted spore dispersal imposed by the position of the capsule. Even the smallest of the plants shows copious fungal infection of the rhizoids and tissues. Like the adult, the young plants are devoid of chlorophyll.

The plant is being more fully investigated, both anatomically and experimentally, since it obviously may yield facts of interest in relation to the general problems raised by the mycorrhizal condition both in liverworts and in other plants. The systematic position of the liverwort and the question of nomenclature will also have to be considered.

Photoperiodic Control of Leaf Growth and Cambial Activity in *Pinus sylvestris*

It has long been known[1] that geographical races of *Pinus sylvestris* from northern latitudes show reduced growth of the shoot when planted in more southern localities. Sylven[2] and Langlet[3] suggested that this is probably a photoperiodic effect, arising from differences in the natural length of day between different localities. My experiments have shown that *Pinus sylvestris* is indeed photoperiodic. As in many other species[4], short photoperiods (10 hr.) induce earlier cessation of growth of the shoot in first-year seedlings of *P. sylvestris* as compared with long photoperiods (15 hr.), so that fewer leaves are formed before the formation of a terminal resting-bud. There is also a reduction in the length of the 'internodes', leading to a rosette type of growth, under short days.

After the first year, however, growth of the annual shoot consists solely of expansion of the initials already laid down in the terminal bud[5], and hence in older plants day-length can have no direct effect on the duration of growth of the shoot or on the number of leaves formed. There is, however, as in first-year seedlings, a reduction in the extension of the stem under short days, leading to a shorter distance between successive dwarf shoots.

The leaves of *Pinus sylvestris* are organs of 'indeterminate' growth, and activity of the meristem at the base of the needles results in their continuous growth in length until late August under natural day-length conditions; under a 10-hr. photoperiod, however, they cease growth six to eight weeks sooner, so that their final length is much reduced. It seems probable that cessation of needle-growth in the autumn is controlled by the reduced day-length conditions then prevailing.

Day-length is also found to affect the duration of cambial activity. Two series of two-year-old seedlings of *P. sylvestris* were kept under (*a*) natural and (*b*) 15-hr. photoperiods respectively from the end of August (when leaf-growth had ceased), the longer photoperiod being obtained by giving supplementary low-intensity (20–25 foot-candles) illumination to extend the natural photoperiod. Wight[5] has pointed out that in *P. sylvestris* a dormant cambium can be distinguished from an active one by the fact that in the former there is a sharp boundary between the cambial cells and fully lignified xylem elements, whereas in the presence of an active cambium there is a zone of partially lignified tracheides between the cambium and the fully differentiated elements. Using this criterion, an examination of the two series of plants at the end of October showed that under the natural day-length conditions the cambium was dormant or showed only slight activity, whereas in the majority of the plants under the 15-hr. day the cambium was still very active. Confirmation of these results was obtained in other experiments in which constant photoperiods of 10 hr. and 15 hr. respectively were used.

In poor specimens the cambium was dormant irrespective of the day-length treatment, and hence it would appear that nutritional conditions also affect the duration of cambial activity. Provided these other conditions are not limiting, however, cessation of cambial activity in *P. sylvestris* is evidently controlled by the reduced natural day-length in the autumn, and is probably only one indication of the incidence of a general state of dormancy, which in deciduous species includes photoperiodic induction of leaf abscission[6]. The inhibition of cambial activity by short days is effective only at the end of the growing season, for two-year plants grown under a 10-hr. photoperiod in the spring showed definite (though reduced) secondary growth, at least until the cessation of leaf growth.

Cambial activity, leaf abscission and extension of the stem are processes well known to be controlled[7,8] also by auxin supply, auxin deficiency having the same effect as short photoperiods. It seems possible, therefore, that these photoperiodic effects in woody species result from the action of light on the production or availability of auxin within the plant, and that quite low light intensities are effective.

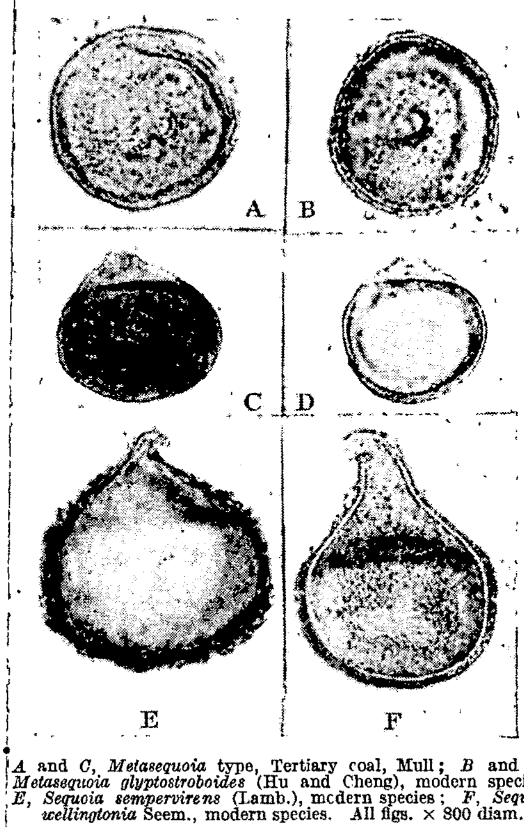
Fossil Pollen of *Metasequoia* Type

Recently, by the kindness of Mr. Orr, of the Royal Botanic Gardens, Edinburgh, I was able to make preparations of the pollen of *Metasequoia glyptostroboides*, the 'living-fossil' discovered in China a few years ago. On examining this pollen, I was at once reminded of certain fossil grains observed in Tertiary coal from Mull, Scotland, which I had been unable to match to my complete satisfaction with the grains of any living conifer. They showed characters most suggestive of *Glyptostrobus* and *Taxodium* and, less closely, of *Sequoia*.

The striking resemblance of these fossil grains to *Metasequoia* pollen, however, will now be evident from the accompanying photograph. *A* and *B* are corresponding polar views of fossil and living grains; *C* and *D* are, likewise, meridional views. In the meridional view the coniform process with its curved tip (an air sac at the distal pole of the grain) is



A and *C*, *Metasequoia* type, Tertiary coal, Mull; *B* and *D*, *Metasequoia glyptostroboides* (Hu and Cheng), modern species; *E*, *Sequoia sempervirens* (Lamb.), modern species; *F*, *Sequoia wellingtonia* Seem., modern species. All figs. × 800 diam.

practically identical in shape, while in the polar view the optical section through the curved tip is also very similar. It will be noted that these grains are quite distinct from the pollen of *Sequoia sempervirens* and *Sequoia wellingtonia*, which are shown for comparison (*E*, *F*).

Despite a prolonged search in the Mull coal, I have not seen pollen resembling that of the living species of *Sequoia*. It would, indeed, be interesting if other lines of palæobotanical research on *Sequoia*-like material of British origin, for example, examination of leaf cuticle, seed and wood anatomy, also suggest relationship to *Metasequoia*.

Brillouin Zone Effects in Aluminium Alloys

IN experiments on the solid solutions of zinc in aluminium, it has been found that there are marked deviations from Vegard's law in alloys containing less than 25 atomic per cent zinc. The deviations of the lattice spacing/composition curve from a straight line are a maximum at 16·5 atomic per cent zinc, coincident with the formation of the α'-phase at 275° C. Further, when the α'-phase is formed, the lattice spacing of the α-phase remains constant over the composition range 16·5–25 atomic per cent zinc and the corresponding temperature change from 275° to 315° C.

These results have led to a more detailed examination of the solid solutions of zinc in aluminium, and it has been found by density measurements at 283° and 318° C. that a defect lattice of the type reported by Bradley and Taylor[1] is formed, there being 5·6 per cent vacant lattice sites at 16·5 atomic per cent zinc (assuming that the pure aluminium which was used as a standard in the density measurements contained no vacant lattice sites) and less than 0·5 per cent vacant sites at 25 atomic per cent zinc. It would appear that the slope of the lattice spacing/composition curve can be correlated with the formation of vacant lattice sites in the solid solution, and that in the composition range 16·5–25 atomic per cent zinc, where the α'-phase is in equilibrium with the α-phase, the lattice spacing remains constant while the vacant sites fill up.

By the formation of vacant lattice sites the electron concentration per unit cell is reduced, and it would appear probable that the electron concentration at the point where the number of vacant lattice sites is a maximum corresponds with the filling of a Brillouin zone. In this case it is of the order of 2·68 electrons per atom, taking into account the effect of the vacant lattice sites.

It has been pointed out by Fink and Freche[2] that the plot of log S against $1/T$ gives a straight line for a number of aluminium-rich solid solutions, where S is the atomic percentage of the solute in solution at the limit of the solid solution at T° Abs. It is found that the solution of zinc in aluminium does not obey this law, and this is further evidence that this solid solution is abnormal.

The aluminium–magnesium and aluminium–silver systems also have fairly wide aluminium-rich solid solutions. Neither solution obeys the law of Fink and Freche, and by analogy with the aluminium–zinc system, this may also be due to the formation of vacant sites.

It is suggested that an electron atom ratio of about 2·68 corresponds with the filling of a zone in these alloys. Such a suggestion, however, is not in accord with the $N(E)$ curve for aluminium recently calculated by Matyas[3].

Application of Similarity to Anelasticity

KE[1] has shown that, when the internal friction and relaxation of rigidity for very pure aluminium are measured as functions of grain size (D), temperature (T) and frequency of vibration (ω), the effects of these three variables can be stated in terms of a single parameter:

$$D.\omega.\exp H/RT, \tag{1}$$

where H is an activation energy of 32,000 cal./mol. The exponential term represents[2] the temperature variation of the coefficient of intergranular viscosity. This parameter has the disadvantage that it is not dimensionless, so that it is not possible to transfer the results of Ke's experiments to other metals. It is therefore of interest to apply dimensional analysis to this system in the attempt to derive a dimensionless criterion for the ratio of the relaxation time $\bar{\tau}$ to the vibration time $1/\omega$. Lord Rayleigh[3] has pointed out that fundamental laws can frequently be derived by such dimensional analysis.

One way of doing this is to start from the fundamental equation for a standard linear solid given by Zener[4] in the form

$$\tau + t_\gamma\dot{\tau} = G_R(\gamma + t_\tau\dot{\gamma}), \tag{2}$$

where τ is the shear stress, γ is the strain, G_R is the relaxed rigidity modulus, t_γ, t_τ are the relaxation times for stress and strain respectively under constant strain and stress. The geometric mean relaxation time $\bar{t} = \sqrt{t_\gamma t_\tau}$ represents the measure of the time-scale of the system governed by equation (2). To apply similarity theory it is, however, necessary to introduce a viscosity[5]

$$n = \bar{t}\,.\,\bar{G} = t_\gamma\,.\,G_u = t_\tau\,.\,G_R, \tag{3}$$

where $\bar{G}$ is the geometric mean of the relaxed (G_R) and unrelaxed (G_u) rigidity moduli. Equation (2) then takes the form

$$\tau + (\eta/G_u)\dot{\tau} = G_R\gamma + \eta\dot{\gamma}, \tag{4}$$

and the dimensionless parameter for the transition from the relaxed (ω small) to the unrelaxed (ω large) states is

$$N_1 = \omega\bar{t} = \omega\eta/G. \tag{5}$$

This introduces the exponential term, since the viscosity can be expected to vary with temperature as $\exp H/RT$; and it is now in dimensionless form, so that it might reasonably be expected to enable results to be transferred from one metal to another by ascertaining suitable values of η and $\bar{G}$. The nalogy with Reynolds's criterion for the transition om non-turbulent to turbulent states as the flow elocity is varied is very attractive. The analogy is arried still further by the fact that, in the viscous rain-boundary system, the shapes of the transition urves for elastic modulus and damping capacity epend also upon the dimensionless ratio G_R/G_u, ust as the friction factor depends upon the roughess ratio as well as the Reynolds number. This atio G_R/G_u has been shown by Zener[6] to depend nly on the Poisson ratio.

This method of approach does not, however, enable he effect of grain-size to be introduced; but a ethod based on Ke's own argument may be used or this purpose. If a crystal is supported a distance away from another crystal by a liquid of viscosity , and a shear stress τ is applied to it, it will move ith a steady velocity

$$v = \frac{\tau \, . \, d}{\eta}. \tag{6}$$

he relaxation time $\bar{t}$ is proportional to the time for he crystal to move with velocity v a distance proortional to the amount of elastic shear in its own ross-section, namely, a distance $D\tau/\bar{G}$, where D is he mean dimension of the crystal. Hence

$$\bar{t}' = D\tau/v\bar{G} = D \, . \, \eta/d\bar{G}. \tag{7}$$

he corrected dimensionless parameter is thus

$$N_2 = \omega\bar{t}' = \frac{\omega \, . \, D \, . \, \eta}{d\bar{G}}, \tag{8}$$

o that the effect of grain-size enters as the dimensioness ratio of the grain-size to the boundary-layer hickness. Since the latter is almost certainly indeendent of the grain-size, N_2 is the dimensionless orm of Ke's parameter (1). It will be of considerable nterest to see whether the results can be transferred rom one metal to another by means of this paraeter, either by deriving a value of η, the effective rain-boundary viscosity for each metal, or, by eriving a value of η/d, the coefficient of boundary lip. From the point of view of dimensional analysis ither is, of course, suitable, because d, the boundaryayer thickness, is likely to be a property of the articular metal concerned, since Mott's work[7] shows hat the boundary is merely a surface of contact of wo crystals. Mott's paper further leads to the uggestion that for different metals η/d should be a unction of the dimensionless quantity H/L, where is the latent heat of fusion. In any event, however, imilarity theory may provide a useful link between e's empirical formula and fundamental theory, if it an be shown that the values of η/d necessary to ring the results for different metals on to the same urve represent properties of these metals which ppear also in other phenomena.

Dissociation Energy of Carbon Monoxide

A SUMMARY of the various recent views on the dissociation energy of carbon monoxide is given by Gaydon[1] in his "Dissociation Energies", in which he eliminates all proposed values except 11·11 and 9·85 eV., and finally accepts the former as being the more probable. At about the same time, Kenty, Aicher, Noel, Paritsky and Paolino[2] observed a new band system of molecular oxygen in a gas discharge containing carbon dioxide which suggested a lower limit for D (CO) of 9·4 eV. Since then, Hagstrum[3] has defended his electron-impact value of 9·6 eV., Gĕro[4] through Valatin[5] still retains faith in 6·9 eV., and Brewer, Gilles and Jenkins[6] have made a determination of the heat of sublimation of graphite which indirectly supports 11·1 eV. Due to this confusion, which has now persisted for some time, the spectroscopic method of evaluating dissociation energies is in danger of being regarded with cynicism by those physical and organic chemists who urgently need this constant for carbon monoxide. The trouble lies in the lack of any dissociation continuum in the spectrum of carbon monoxide, and accordingly attention has been centred on predissociation phenomena, of which there seems no lack.

I have been working on the electron configurations of the various excited states and have been attracted by the F$^1\Pi$-state. This has such a large $x\omega$ (198 cm.$^{-1}$) that it has probably the flattest potential energy curve of all the states of carbon monoxide and consequently the smallest D value. A linear extrapolation gives 0·5 eV., and if we know the dissociation products it is clear that D for the ground state can be determined without appealing to predissociation. Now this state is definitely a singlet because of the high intensity of the F $\leftarrow X^1\Sigma$-transition, and consequently must dissociate into either two triplet atoms ^3P(C) + ^3P(O) or two singlets. The former possibility can be ruled out, and the most probable pair of atoms is ^1D(C) + ^1D(O). The energy difference between ^3P(C) + ^3P(O), the ground-state products, and ^1D(C) + ^{1}D(O) being 3·3 eV., we find 9·6 eV. for D(CO), and if we allow 0·3 eV. as a possible error in the extrapolation of the F-state, the D-value will be uncertain by this amount. This estimate is in agreement with either the predissociation value of 9·85 eV. or Hagstrum's 9·6 ± 0·1 eV., and leads to a value for L(C) of 130–140 kcal.

H. G. HOWELL

[6] Brewer, L., Gilles, P. W., and Jenkins, F. A., *J. Chem. Phys.*, **16**, 797 (1948).

OF the many values which have been suggested for D(CO), the high value of 11·1 eV. and Hagstrum's value of 9·61 eV. seem most likely, as recently pointed out[1]. Dr. Howell's discussion of the F$^1\Pi$-state certainly gives strong support to the latter value. It should be remembered, however, that Birge–Sponer extrapolations for highly excited states may not be reliable, and indeed may be quite anomalous, as for silver hydride. Also it is likely that for the excited states of carbon monoxide there may be potential maxima, and the limit of the extrapolation will then be the maximum instead of the dissociation limit. In the reaction zones of flames much of the light emission is due to chemiluminescence, and it is not easy to account for this unless we are able to postulate reactions which are highly exothermic and which require the high value for D(CO). The 9·61 value would, however, give a more satisfactory comparison with the iso-electronic molecule N_2, for which I favour a dissociation energy of 9·76 eV.

Thixotropic Behaviour of Petroleum Jelly

IN my earlier communication[1] I directed attention to the reversible change of consistency brought about by the slow and fast shear of petroleum jelly. The present note embodies more precise observations, but it is evident that further work still is needed to interpret the mechanism of the phenomena.

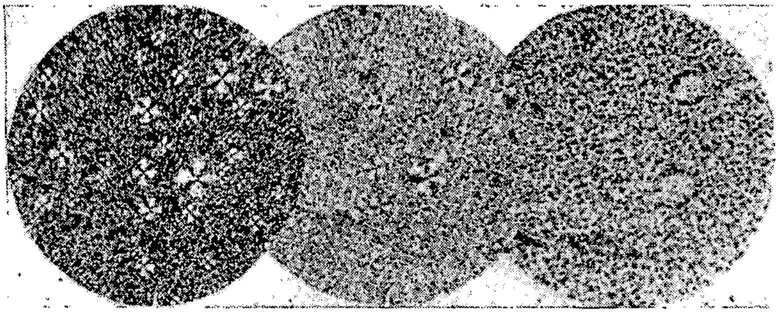
When threshold rigidities are measured in a modified form of parallel-plate plastimeter, reproducible values are not obtainable on the bulk material which has been melted and allowed to cool, owing to heterogeneity of crystalline disposition throughout the mass. However, treatment for a few hours in a slow-running Werner–Pfleiderer mixer reduces rigidity to the minimum value characteristic of slow churning. A parallelism between the results obtained by churning and by treatments under more accurately specified conditions is shown in the following table:

Rigidities by parallel-plate plastimeter

1.	After 2 hours in Werner–Pfleiderer mill	15 dynes/cm.^{2}
2.	Followed by two successive shears through a glass capillary at 35,000 dynes/cm.^{2} stress	57 ,,
3.	Treatment (2) followed by capillary shear at 1,350 dynes/cm.^{2} stress	38 ,,
4.	Treatment (2) followed by capillary shear at 2,700 dynes/cm.^{2} stress	41 ,,
5.	Treatment (2) followed by capillary shear at 5,200 dynes/cm.^{2} stress	48 ,,

It is evident from the fact that treatment (3) has not resulted in reducing the rigidity to its original value that the number of operations was inadequate and/or the shear stress was too high to effect a complete reduction of rigidity to the value shown by (1). In all cases shear was kept well below the limit of incidence of turbulent flow.

I have already referred[2] to a thixotropic anomaly in the capillary shear of petroleum jelly, but uncertainty as to the significance of 'yield value' obtained as an intercept of the stress-shear line to the stress axis does not justify its discussion in the present communication.



(a) (b) (c)

Liquid crystals in milled petroleum jelly (× 50). (a) Nicols crossed, black field; (b) nicols in phase, white field; (c) unpolarized light

It is interesting to note that prolonged treatmen in the Werner–Pfleiderer mixer results in the formation of liquid crystals.

Auroral Displays at Saskatoon

A VERY intense auroral display was observed a Saskatoon during the night of January 24–25. Th display began as a red aurora at 6.15 and the re colour persisted until 7.45; all times mentioned ar Mountain Standard Time (seven hours behin G.M.T.). Some red was present at all times up t midnight. At 7.30 the display consisted of two re sheets in the east and west, and a beautiful coron near the zenith. The corona was green overhead, an red near the eastern and western borders. Thre homogeneous arcs were present at 8.00, one in th north at altitude 15°, a second passing throug the zenith, and a third in the south at altitude 10° All auroral forms were present at some tim during the display, which lasted until dawn Newspaper reports indicate that the red auror was seen in British Columbia and as far south a California.

A second intense display occurred during the nigh of February 21–22. Again all auroral forms appeare during the display, and some red colour was observe at times. During most of the night an arc passin through the zenith extended from horizon to horizon At times this arc was extremely bright.

A photograph of the sun's surface taken at noo on January 24 showed a large sunspot group abou two days past the solar meridian. On February 2 this group was still present although considerabl reduced in size.

A new high light-gathering power grating spectrograph was put into operation for the first time o February 21. This instrument gives a dispersion o 20 A./mm. A four-hour exposure gave a spectrogra which included two weak features at the position of $H\alpha$ and $H\beta$.

STATISTICAL MECHANICS OF SOME CO-OPERATIVE PHENOMENA

By C. DOMB

Pembroke College, Cambridge*

THERE are a number of co-operative phenomena associated with specific heat singularities for which the technical mathematical problems are formally similar. These include the Ising model of a ferromagnetic, the theory of regular binary solid solutions, and the order–disorder transitions in alloys. Many approximations have been devised for treating these problems, and as a typical example we may quote the Bethe approximation[1]. It was at first considered that these approximations provided a satisfactory account of the thermodynamics of the problems. Recently, however, the exact solution of a particular problem by Onsager[2,3] has shown that the standard approximations are unreliable in the neighbourhood of the singularity, and has focused attention on exact solutions.

It is clarifying to consider the above problems collectively, and in a recent paper[4] it has been shown that, if only nearest neighbour interactions are taken into account, the thermodynamic properties are completely determined by a function $\Lambda(\mu, z)$ of two positive variables μ and z. For the ferromagnetic problem, the free energy is given (except for a zero-order term) by

$$F = -nkT\,[\log \Lambda(\mu, z) - \tfrac{1}{2} \log \mu], \tag{1}$$

where $z = \exp(-\varepsilon/kT)$, $\mu = \exp(-2mH/kT)$, and ε is an interaction energy. In the regular solution and order–disorder problems, the corresponding free energy is

$$F' = -nkT\,[\log \Lambda(\mu, z) - \alpha_1 \log \mu], \tag{2}$$

where μ now depends on α_1, the mole fraction of constituent 1, and is determined by the relation

$$\mu\Lambda_\mu/\Lambda = \alpha_1. \tag{3}$$

It is easy to establish the relation

$$\mu^{-1/2}\,\Lambda(\mu, z) = \mu^{1/2}\,\Lambda(1/\mu, z), \tag{4}$$

and this means that only values of μ from 0 to 1 need be considered. The ferromagnetic and regular solution problems correspond to values of z between 0 and 1, and we shall discuss them shortly. The order–disorder and anti-ferromagnetic problems correspond to values of z^{-1} between 0 and 1, and we shall not consider them further here.

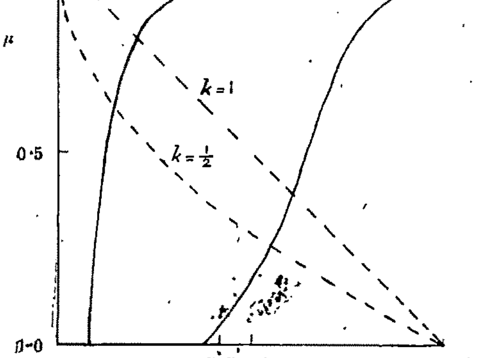

Fig. 1

It is well known that a one-dimensional system does not exhibit sharp phase transitions[5], and therefore, to obtain information of interest, we must proceed to a two-dimensional system. In the paper referred to above[4], a generalization of some earlier work of Kramers and Wannier[6] shows that $\Lambda(\mu, z)$ is the largest eigenvalue of an infinite matrix of simple characteristic structure. A discussion of the properties of $\Lambda(\mu, z)$, and hence of F and F', is best undertaken with the aid of Fig. 1, which represents the (μ, z) plane. Onsager's solution applies to the line AB, and starting at A (corresponding to $T = 0$) a power series may be derived, of which the first terms are the following:

$$\Lambda(1,z) = \lambda(z) = 1 + z^4 + 2z^6 + 5z^8 + 14z^{10} + 44z^{12} + 152z^{14} + \ldots \tag{5}$$

This series is valid up to the Curie point C ($z = 0{\cdot}414$) and gives rise to a logarithmic infinity in λ_{zz} (specific heat singularity) at C. The following generalization of this series for values of μ other than 1 has been obtained:

$$\begin{aligned}\Lambda(\mu,z) = {} & 1 + \mu z^4 + 2\mu^2 z^6 + (-2\mu^2 + 6\mu^3 + \mu^4)z^8 + (-14\mu^3 + 18\mu^4 + 8\mu^5 + 2\mu^6)z^{10} + \\ & (8\mu^3 - 77\mu^4 + 44\mu^5 + 40\mu^6 + 22\mu^7 + 6\mu^8 + \mu^9)z^{12} + (98\mu^4 - 370\mu^5 + 40\mu^6 + 138\mu^7 + \\ & 134\mu^8 + 72\mu^9 + 30\mu^{10} + 8\mu^{11} + 2\mu^{12})z^{14} + \ldots\end{aligned} \tag{6}$$

Substitution of $\mu = 1$ in (6) gives back (5), so this series seems to be valid up to $\mu = 1$, and there is no discontinuity in Λ at $\mu = 1$. On the other hand, we can deduce from (4) that $\Lambda_\mu/\Lambda = 1/2$ at $\mu = 1$, whereas from (6) $\Lambda_\mu/\Lambda \rightarrow \beta(z)$ as $\mu \rightarrow 1$, where

$$\lambda(z)\beta(z) = z^4 + 4z^6 + 18z^8 + 82z^{10} + 387z^{12} + 1880z^{14} + \ldots \tag{7}$$

Thus there is a discontinuity in Λ_μ as $\mu \rightarrow 1$ in the neighbourhood of A, which one would expect to persist as far as C. High-temperature expansions starting at B indicate (as one would expect) that this discontinuity does not persist beyond C.

Onsager's solution for $\mu = 1$ corresponds to a ferromagnetic in the absence of a magnetic field, and values of $\mu < 1$ correspond to the presence of a magnetic field. The magnetization is given by $-\partial F/\partial H$ in (1), and hence by

$$I/I_\infty = 1 - 2\mu\Lambda_\mu/\Lambda. \tag{8}$$

Thus the discontinuity in Λ_μ gives rise to a spontaneous magnetization

$$I_0/I_\infty = 1 - 2\beta(z), \tag{9}$$

which is shown as a function of z in Fig. 2. In the presence of a constant magnetic field, the thermodynamic properties are obtained by following a curve of the form $\mu = z^k$, where k is a measure of the strength of the field. A study of the terms of (6) for values of $\mu < 1$ indicates a completely different behaviour from that for $\mu = 1$, caused by the large negative term in the coefficient polynomials in μ. This is shown by the accompanying table.

For $\mu = 1$, the terms are all positive and steadily increase, and this means a singularity on the real

---

* Now at the Clarendon Laboratory, Oxford.

Coefficient of:	z^4	z^6	z^8	z^{10}	z^{12}	z^{14}
$\mu = 1$	1	2	5	14	44	152
0·9	0·9	1·62	3·41	7·39	16·04	32·19
0·8	0·8	1·28	2·20	3·35	3·21	−5·48
0·7	0·7	0·98	1·32	1·10	−1·44	−10·92

axis[7]. On the other hand, for $\mu = 0{\cdot}7$ and $0{\cdot}8$, the terms cease to increase steadily, and there are strong indications that for any $\mu < 1$ the coefficients are not consistent in sign beyond some point. This leads one to conjecture that the specific heat transition becomes continuous in the presence of a magnetic field, which is also the result given by the Heisenberg theory.

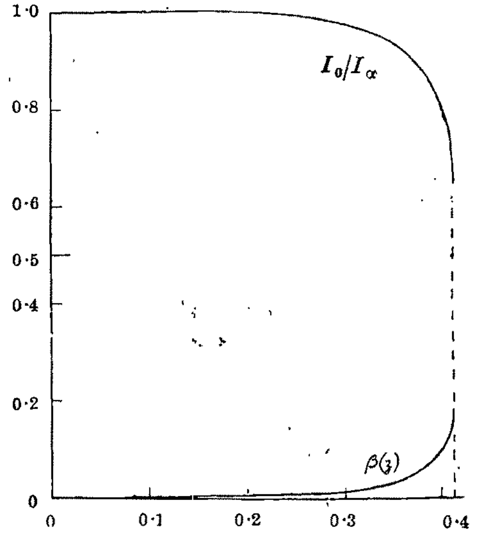

Fig. 2

The exact theory of binary solid solutions was considered by Lassetre and Howe[8], and we shall find many of their conclusions here substantiated. Considering the thermodynamics of a solid solution of fixed constitution, we must follow a path in the (μ, z) plane given by (3). When $\alpha_1 = 1/2$, this is the path AB in Fig. 1. When α_1 is different from 1/2, however, a completely different type of path results. When $z < 0{\cdot}414$, the general behaviour of $\mu\Lambda_\mu/\Lambda$ as a function of μ is similar to the curve in Fig. 3 (for $z = 0{\cdot}4$). Its value steadily increases from zero at $\mu = 0$ to $\beta(z)$ at $\mu = 1$, and there is a jump to 1/2 at $\mu = 1$. This discontinuity arises for an infinite lattice, and would be a very rapid continuous change for a large finite lattice. Hence if $\beta(z) < \alpha_1 < 1/2$, the relation (3) can only be satisfied on the line AB. For very high temperatures it can be shown that (3 leads to $\mu = \alpha_1/(1-\alpha_1)$. Thus for any value of α different from 1/2, the path given by (3) moves alon AC until $\beta(z) = \alpha_1$, and then it turns into the plan cutting BE in a point $\mu = \alpha_1/(1-\alpha_1)$. Typica paths are $A\,C_1\,B_1$, $A\,C_2\,B_2$ in Fig. 1.

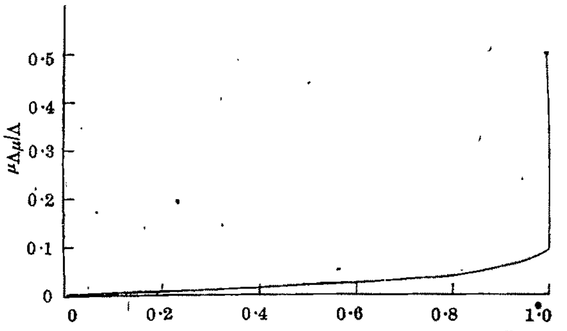

Fig. 3. ($z = 0{\cdot}4$)

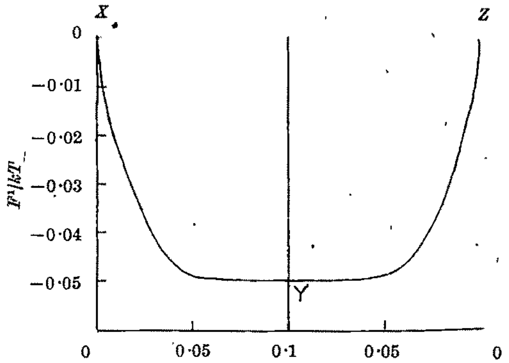

Fig. 4. ($z = 0{\cdot}4$)

Clearly a transition takes place at points such a C_1, and we shall interpret the portion AC_1 as corresponding to a separation into two phases, and th portion $C_1 B_1$ as solution. This interpretation i borne out by the curve of free energy as a functio of concentration, which for $z < 0{\cdot}414$ is of the form shown in Fig. 4. The point on AC in Fig. 1 corresponding to the value of z considered may b regarded as a mixture of two phases at Y in Fig. 4 phase I being a solution of $\beta(z)$ of substance 1 i substance 2, and phase II a solution of $\beta(z)$ of substance 2 in substance 1. $\beta(z)$ is thus the maximum concentration which can exist in solution at the give temperature, and is, in fact, the solubility curve fo the given substances; it is shown in Fig. 2. A we move along AC_1, the proportion of phase I gets smaller, until at C_1 it disappears.

The nature of the transition at C_1 can be determined from (2) and (3). There is a discontinuity i μ_z at C_1 given by

$$\underset{\mu\to 1}{Lt}\ \frac{\alpha_1\,\Lambda_z - \mu\Lambda_{\mu z}}{\mu\,\Lambda_{\mu\mu} + (1-\alpha_1)\Lambda_\mu}. \qquad (10$$

On the other hand, $(F'/T)_\mu = 0$, so that $E = n\varepsilon z\,\Lambda_z/\Lambda$, and this does not involve μ_z. Thus th energy is continuous, but the specific heat has discontinuity given by

$$nk(z\log z)^2\ \underset{\mu\to 1}{Lt}\left[\mu_z \frac{\partial}{\partial_\mu}\left(\Lambda_z/\Lambda\right)\right], \qquad (11$$

so that the transition is second order.

It does not seem unreasonable to assume that with the exception of the detailed behaviour at th singularity C, the above discussion should be qualitatively applicable to a three-dimensional model.

I am indebted to Prof. M. H. L. Pryce and Dr G. S. Rushbrooke for helpful discussion and to th Department of Scientific and Industrial Research fo a senior research award.

TUMOURS ASSOCIATED WITH A VIRUS INFECTION IN AN INSECT

By F. T. BIRD
Division of Entomology, Department of Agriculture, Ottawa

REPORTS of tumours in insects are relatively rare. Paillot[1] mentions proliferation in the fat cells of *Euxoa segetum* Schiff., following infection by virus diseases (pseudo-grasseries I and II). Tumours have been described in the fruit-fly, *Drosophila melanogaster* Meigen, by Stark[2,3,4] and Russell[5]; in larvæ of the Pygæra group of butterflies, by Federley[6]; and in the stick insect, *Dixippus morosus* Br., by Pflugfelder[7]. They have been found in a large Orthopteran insect, *Leucophæa maderæ* F., by Scharrer[8].

All the tumours so far discovered in insects are apparently non-malignant, although malignancy has been claimed by Stark[2] and Federley[6]. Russell[5] found that those in *Drosophila* reported by Stark as malignant were similar in structure to benign tumours occurring in the same insect, and that the so-called malignant tumours could be successfully transplanted without hampering the development of the host. The tumour strains discovered by Federley apparently have been lost.

Various stimuli will provoke tumour proliferations in insects. Spontaneous tumours occur in several genetic tumour strains in the fruit-fly, but the stimulus is not known. Russell suggests that certain abnormalities which occur in the mid-gut epithelium of the lethal 7 strain may cause abnormal cell proliferations. In the stick insect, proliferation accompanies cell degeneration following the removal of the corpora allata, organs of internal secretion. In *Leucophæa*, Scharrer has shown that tumours are formed in the mid-gut and salivary reservoir, and to a less extent in the fore-gut and salivary glands, when the recurrent nerve, which innervates these organs, is cut at various levels.

In the course of a study of a virus polyhedral disease of the European spruce sawfly, *Gilpinia hercyniæ* (Htg.)[9], tumours were observed in the mid-gut after infection of the epithelium by the virus. The following is a brief description of the origin and nature of the tumours, pending a more detailed account of the disease to be published elsewhere.

The mid-gut epithelium of the normal sawfly larva is made up of large columnar digestive cells, a basement membrane, an inner circular and an outer longitudinal muscle coat. The lattice work of muscle fibres covers but a part of the epithelial cells; in many places these are separated from the circulating blood only by the basement membrane and a delicate connective tissue sheath. Among the large digestive cells there are groups or *nidi* of small basal, embryonic or regenerative cells located just beneath the basement membrane. The function of the regenerative *nidi* is (1) to propagate cells, (2) to replace the large cells when the latter are exhausted by digestive activities, (3) to add to the number of digestive cells during the moulting periods of young larvæ, and (4) to replace the digestive epithelium at the time of the last larval moult and during pupation.

During the moulting period of a young larva, new cells are passed gradually from the regenerative *nidi* into the digestive epithelium. This is accomplished without any appreciable increase in the size of the *nidi*. At the time of the last larval moult, the digestive epithelium is completely replaced. The digestive cells disintegrate slowly and at the same time there is an increase in the number of cells of each regenerative *nidus*. A new mid-gut is formed when adjacent *nidi* converge. All the cells do not enter into the functional epithelium. A few remain at the bases of the digestive cells, where they form the regenerative *nidi* of the new mid-gut. Most of the materials of the old larval gut are absorbed, but an indigestible part is evacuated after ecdysis. Soon after this evacuation, the larva spins a cocoon and at this stage is termed an eonymph. The mid-gut of the eonymph is similar to that of the young larva. It is a temporary gut, however, and soon the digestive cells again disintegrate, and cells are propagated by the regenerative *nidi* to form the adult mid-gut.

In the diseased larva, the virus affects only the digestive cells of the mid-gut epithelium. When infection takes place and nuclear transformations occur which finally result in the formation of polyhedral bodies, abnormal cell proliferations appear in the regions of the regenerative *nidi* (Fig. 1). There is no increase in the size of the *nidi* at this time. Apparently a few cells are released and multiply rapidly to form the proliferations. Most of these project into the body cavity, but infiltration into the cytoplasm of the digestive cells does occur. This is similar to, but more intense than, that which takes place during the moulting period of a healthy larva.

Large tumours are formed only when the larva becomes infected just prior to the last larval moult. All the materials necessary for further metamorphosis

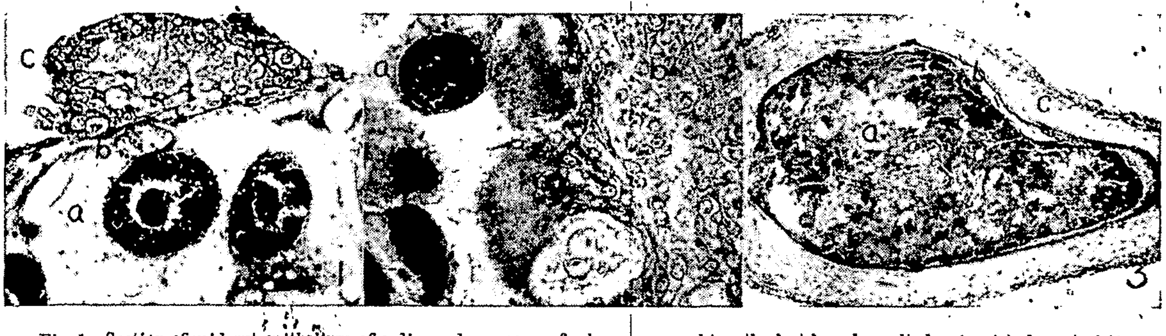

Fig. 1. Section of mid-gut epithelium of a diseased spruce sawfly larva approaching the last larval moult showing (*a*) characteristic granulation of nuclear material as a result of disease infection, (*b*) regenerative *nidus*, and (*c*) proliferating cells. × 270

Fig. 2. Section of mid-gut epithelium of an eonymph showing (*a*) disease nuclei and (*b*) proliferating cells. × 270

Fig. 3. Section of a mature tumour of the spruce sawfly showing (*a*) necrotic mass of epithelial origin, (*b*) thin layers of tissue formed from proliferating cells, and (*c*) a loose mass of proliferating cells. × 45

are accumulated at this time, and normal cell proliferation and replacement takes place. When larvæ become infected at an earlier stage, death from the effect of the disease occurs before these abnormal proliferations progress very far. The infection process and abnormal cell proliferations continue in the eonymphal gut. The sizes of the tumours depend on the areas of cell infection. In the case of total infection there is a general swelling of the entire eonymphal gut. The centre of a growing tumour consists of an accumulation of dead cells. This is surrounded by greatly enlarged infected cells. The whole is surrounded by a mass of proliferating cells (Fig. 2).

The tumours rapidly mature during an early stage of pupation. Cell infection and abnormal cell proliferation cease at the time of the normal disintegration of the digestive cells of the eonymphal gut. General infection takes place after the adult gut is formed, but from the time of the breakdown of the eonymphal digestive epithelium until the adult gut is formed cell infection by the virus appears to be inhibited. If the infection process and tumour formation have not continued too far, a normal gut may be formed around the tumours and the insect survives. Many of the tumours remain within the gut during pupation. Because the mid-gut of the adult is much shorter than that of the eonymph, some of the tumours may be pushed out into the body cavity during pupation, where they remain as non-living, hard, dark-brown pellets throughout the life of the adult. Those which remain within the gut are subject to the action of digestive juices and may disappear. The mature tumour consists of a necrotic, pigmented mass of epithelial cells surrounded by thin tissue layers formed from the small proliferating cells (Fig. 3).

There is no evidence of infiltration of the tumour cells into any other organ in the spruce sawfly. All the evidence indicates that the tumours are non-malignant.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

THE fifty-third annual congress of the South-Eastern Union of Scientific Societies was held at Canterbury during April 19–23, at the invitation of the Mayor and Corporation, with the co-operation of the Dean and Chapter.

In his address the president, Mr. F. H. Edmunds, district geologist for south-east England in the Geological Survey, gave a broad picture of the evolution of State Geological Surveys in the various countries of the world. He indicated how their inception, in the first half of the nineteenth century, was intimately linked with the birth and growth of the science of geology, which itself is but some 150 years old. The basic principles of geological science were formulated largely as the result of the work of James Hutton in Scotland and William Smith in England; Smith produced the first real geological map. Once these principles had been grasped, the economic importance of the geological map became immediately apparent to Governments everywhere. The Geological Survey of Great Britain was established in 1835, and it was almost immediately followed by those of Canada and India. To-day practically every civilized country in the world possesses its Geological Survey.

Mr. Edmunds said that geological research is the scientific study of the foundation of all our surroundings, and its application touches us, either directly or indirectly, in our everyday life in many directions one obvious way is in assisting in the discovery of economic minerals—coal, oil, minerals, etc.—and there are also numerous other less apparent ways Geological maps of a country which give detailed accurate data of the surface layers of the land are particularly valuable in densely populated countries in connexion with the many and widespread civi engineering works which are always in progress and which vary from foundation work for buildings to bridge-building, road-making and surface water storage, reservoir and dam-building, and from digging trenches for water, gas and sewage mains to sinking wells for water supply. Geological Surveys have also a cultural function, instanced by the identification by the Geological Survey of Great Britain of the types of rock and, in many cases, of their sources, which were used in making archæological objects, such as thos revealed in bombed sites in Canterbury during the Second World War.

As social development proceeds towards planning and nationalization, as it is doing in Great Britain the influence of the work of a Geological Survey on the implementation of policies becomes very great Again quoting Great Britain, Mr. Edmunds said tha not only was the Geological Survey the officia adviser to the Coal Board, but its work also provides the basic data for decisions by central and loca planning authorities relative to such matters as wher and how sand, gravel, building stones, brick, cement etc., should be quarried or manufactured; indeed, n other basic criteria exist. The search for natura reserves of underground water has long been the function of the Geological Survey; without this previous work, regulation and conservation of underground water, now rendered necessary largely owin to great increases in daily consumption, would be impracticable.

An address on "Roman Canterbury" was delivered to the Archæological Section by its president, S. S Frere, who also conducted a tour of the recent excavations in the City to illustrate points in his address. The keeper of manuscripts at the Cathedral Library, W. Urry, gave a paper on "The Street Plan of Mediæval Canterbury", and later demonstrated t the members on site. Excursions to Minster, Ebbsfleet, Sandwich and Richborough were conducted by Dr. H. Raven. Dr. George Taylor became president of the Botanical Section, the subject of his address being "Remarks upon the Genus Potamogeton" Francis Rose gave a paper upon "Gaps in our Knowledge of the Flora of Kent", and conducted an excursion to Stodmarsh and Trenley Park Wood.

The president of the Geological Section, Arthur Wrigley, spoke on "The Thanet Sand", and conducted an excursion to Bishopstone Gap to examine the Lower Eocene rocks. A paper on "Notes on th Minerals of the Mesozoic and Later Strata of S.-E England" was given by J. C. Taylor. A joint cursion with the Botanical Section to demonstrate e agricultural soils of Kent was conducted by . S. Furneaux.

The Zoological Section, under the presidency of ajor Maxwell Knight, held a symposium on Nature udy, with particular reference to the need for -operation between the museum, laboratory and ld-worker. The leaders on the Stodmarsh–Trenley rk Wood excursion were D. Stainer and R. G. illiams, and the Rev. Laurens Sargent led the ction on an expedition to the estuary of the Stour ar Richborough. An evening was devoted to a nversazione arranged by the local committee. The hibits included manuscripts shown by the Dean d Chapter and the charters of the King's School. and, freshwater and marine life in all sections were splayed.

The 'Young Naturalists' Evening' commenced with 'brain's trust' consisting of a team of experts, C. Bushby, Dr. L. B. Langmead, F. Rose and David th Smith, with Major Maxwell Knight as question aster. Many questions received from students of cal schools were answered. An exhibition of Nature ms taken at the London Zoo by Douglas Fisher as enthusiastically received by an audience from e schools, the hall being filled to capacity.

The next congress will be held jointly with the uth-Western Union at Marlborough during Whitntide, 1950.

NATIONAL ACADEMY OF SCIENCES, UNITED STATES

THE National Academy of Sciences at its annual meeting held in Washington, D.C., during April –27, elected the following officers, members and reign associates.

Vice-president for a four-year term ending in 1953: dwin Bidwell Wilson, emeritus professor of vital atistics, Harvard School of Public Health, Boston, ass.

Members of the Council of the Academy for a three-ar term ending in 1952: Joel H. Hildebrand, ofessor of chemistry, University of California; rnest W. Goodpasture, professor of pathology and an, School of Medicine, Vanderbilt University.

Members: George W. Bartelmez, professor of atomy, University of Chicago; Frank A. Beach, ofessor of psychology, Yale University; Robert B. rode, professor of physics, University of California; aul R. Burkholder, Eaton professor of botany, Yale niversity; Lowell T. Coggeshall, professor and airman, Department of Medicine, and dean, ivision of Biological Sciences, University of Chicago; ax Delbrück, professor of biophysics, California stitute of Technology; Robert C. Elderfield, pro-ssor of chemistry, Columbia University; William F. ibbs, vice-president, Gibbs and Cox, 240 East 79th treet, New York; William W. Hansen, professor of hysics, Stanford University; Charles B. Huggins, rofessor of surgery, University of Chicago; Walter . Lambert, U.S. Coast and Geodetic Survey (retired), ashington, D.C.; Howard B. Lewis, professor and ead of Department of Physiological Chemistry, niversity of Michigan; Francis W. Loomis, pro-ssor and head of Department of Physics, University f Illinois; Thomas S. Lovering, U.S. Geological urvey, Washington, D.C.; Samuel M. McElvain, professor of chemistry, University of Wisconsin; Saunders MacLane, professor of mathematics, University of Chicago; Nicholas U. Mayall, Lick Observatory, Mt. Hamilton, California; Otto Meyerhof, research professor of physiological chemistry, University of Pennsylvania; John S. Nicholas, Sterling professor of biology, Yale University; George B. Pegram, professor of physics and dean of graduate faculties, Columbia University; Kenneth S. Pitzer, professor of chemistry, University of California; Kenneth B. Raper, senior microbiologist, Northern Regional Research Laboratory, U.S. Department of Agriculture, Peoria, Illinois; John L. Savage, chief designer, U.S. Bureau of Reclamation, Denver, Colorado; Carl F. Schmidt, professor of pharmacology, University of Pennsylvania; Julian Schwinger, professor of physics, Harvard University; Harry L. Shapiro, professor of anthropology, Columbia University; Oliver R. Wulf, professor, Division of Chemistry and Chemical Engineering, California Institute of Technology; Ralph W. G. Wyckoff, scientist director, National Institute of Health, Bethesda, Maryland; Frederick W. H. Zachariasen, professor and chairman of the Department of Physics, University of Chicago.

Foreign Associates: Élie Cartan, professor of geometry, University of Paris; Paul A. M. Dirac, Lucasian professor of mathematical physics in the University of Cambridge; Bernard Lyot, astronomer, Meudon Observatory, Seine-et-Oise, France; Henri Piéron, Laboratory of Physiological Psychology, Sorbonne; Arne Tiselius, professor of biochemistry, University of Uppsala; Öjvind Winge, director, Department of Physiology, Carlsberg Laboratory, Copenhagen; Hideki Yukawa, professor of physics, Kyoto University, Japan.

Awards for 1948

The Academy has made the following awards for 1948.

Cyrus B. Comstock Prize of 3,500 dollars: to Dr. Merle Anthony Tuve, director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington, for his pioneering work on the upper atmosphere and his development of the electrical impulse method of study; for his pioneering work in nuclear physics utilizing the electrostatic generator; and for his development of the proximity fuse.

James Craig Watson Gold Medal: to Dr. Samuel Alfred Mitchell, director for more than thirty years of the Leander McCormick Observatory of the University of Virginia, for distinguished services to astronomy, including (1) observations of solar eclipses, in particular a detailed study of the spectrum of the chromosphere which has contributed notably to knowledge of the atmosphere of the sun; (2) determination of the magnitudes of eight thousand comparison stars in 450 fields containing long-period variables, and more than fifteen thousand observations (with others) of 204 of the variables themselves; (3) trigonometrical measurement of the parallaxes of some fifteen hundred stars.

Mary Clark Thompson Gold Medal: to Dr. Frank McLearn, of the Geological Survey of Canada, in recognition of his important contributions to geological knowledge in a number of fields.

Public Welfare Medal: to Prof. George Harrison Shull, emeritus professor of botany and genetics, Princeton University, for his services in the application of principles of the pure line and of hybrid vigour to the improvement of the quantity and quality of the maize crop.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 16

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. F. J. Cole, F.R.S.: "Aspects of Biological Discovery, 3, Life Cycle of a Parasite".*

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.30 p.m.—Prof. Johannes Brøndsted (Copenhagen): "Tribes and Peoples in Scandinavia during the Stone and Bronze Ages".* (Further Lectures on May 18 and May 20.)

Monday, May 16—Thursday, May 19

International Institute of Welding (at the University, Delft, Holland).—Annual Meeting.

Tuesday, May 17

Society of Chemical Industry, Agriculture Group (in the Chemistry Department, Royal College of Science, South Kensington, London, S.W.7), at 2.30 p.m.—Annual General Meeting; at 3 p.m.—Dr. J. G. Davis: "The Scientific Basis of Cheese-Making".

Chadwick Public Lecture (at the Chelsea Physic Garden, Swan Walk, London, S.W.3), at 4 p.m.—Prof. C. T. Ingold: "Spore Dispersal in relation to Plant Disease and Health".*

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. Margarete Weninger: "Anthropological Research Work in Austria".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. J. L. Nicholson: "Variations in Working-Class Family Expenditure".

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. A. C. Branch and Mr. J. L. Sweeten: "The Fabrication of Chemical Plant in Stainless Steel".

University of London (at Birkbeck College, Breams Buildings, London, E.C.4), at 6 p.m.—Sir John Anderson, F.R.S.: Haldane Memorial Lecture.*

Wednesday, May 18

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Alfred Egerton, F.R.S.: "Scientific Information Services" (Aldred Lecture).

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Discussion on "The General Circulation of the Atmosphere" (to be opened by Dr. E. T. Eady).*

Royal Microscopical Society (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Discussion on "Mechanism of Cell Division" (to be opened by Dr. A. F. W. Hughes).

Society of Chemical Industry, Nutrition Panel of the Food Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Annual General Meeting; at 6.15 p.m.—Discussion on "The Nation's Manufactured Foods, 2, Biscuits, Cakes and other Flour Confectionery as Food".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. A. L. Hetherington: "Chinese Ceramic Glazes, with special reference to the Copper Glazes".

Thursday, May 19

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting; at 5.15 p.m.—Mr. W. A. C. Newman: Presidential Address.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. M. J. Lighthill: "A Technique for Rendering Approximations Uniform".

British Institute of Radiology (at 32 Welbeck Street, London, W.1), at 8 p.m.—Annual General Meeting.

Friday, May 20

Chemical Society, Exeter Branch (in the Washington Singer Laboratories, University College, Exeter), at 4.30 p.m.—Sir Ian Heilbron, F.R.S.: "A New Approach to the Synthesis of Azoles and Purines".

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5 p.m.—"Air Navigation".

Physical Society, Acoustics Group (at the Royal College of Organists, Kensington Gore, London, S.W.7), at 5.30 p.m.—Mr. L. E. A. Bourne: "The Development of a new Electronic Organ".

Society of Dyers and Colourists (at the Waldorf Hotel, Aldwych, London, W.C.2), at 7.15 p.m.—Mr. E. Wilson: "Some Applications of Chemistry to Textile Finishing" (Sixth Mercer Lecture).*

Saturday, May 21

British Psychological Society (in the Hastings Hall, Tavistock House, Tavistock Square, London, W.C.1), at 2.30 p.m.—Dr. Otto Friedmann: "Psychopathology and Politics".

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Lecturer in Physics (with an Honours Degree in Physics)— Clerk to the Governors, Woolwich Polytechnic, Woolwich, Lond S.E.18 (May 21).

Lecturer (Grade III) in Applied Mathematics—The Clerk, B beck College, Breams Buildings, London, E.C.4 (May 21).

Teacher of Mathematics with ability to teach Physics and other Science subjects for classes which may reach Degree stand and a Senior Assistant for Physics—The Principal, Munic Technical College, Halifax (May 21).

Laboratory Technician—The Secretary, Mid-Glamorgan Hosp Management Committee, 8 Wind Street, Neath, Glam. (May 21)

Assistant Inspector of Salmon Fisheries—The Establishm Officer, Scottish Home Department, Room 364, St. Andrew's Hou Edinburgh 1 (May 21).

Lecturer in the Civil and Mechanical Engineering Depa ment (to teach mechanical engineering subjects, preferably includ Applied Thermodynamics *or* Engineering Drawing and Design) Engineering Degree and National Certificate courses, and a Lectur in the Applied Physics Department—The Secretary, Northamp Polytechnic, St. John Street, London, E.C.1 (May 21).

Lecturer in Mathematics and Science (either Chemistry Physics)—The Principal, Dudley and Staffordshire Technical Colle Dudley (May 21).

Senior Lecturer in Mathematics—The Clerk to the Govern Chelsea Polytechnic, Manresa Road, London, S.W.3 (May 21).

Engineer III (Instructor) at a Ministry of Supply factory in M mouthshire—The Ministry of Labour and National Service, Techni and Scientific Register (K), York House, Kingsway, London, W.C quoting C.231/49A (May 21).

Lecturer in the Department of Chemistry, to teach Orga Chemistry to the standard of B.Sc. Special Degree, in the Plymou and Devonport Technical College—The Director of Education, Edu tion Offices, Cobourg Street, Plymouth (May 21).

Chair of Geography at the London School of Economics a Political Science—The Academic Registrar, University of Lond Senate House, London, W.C.1 (May 25).

Senior Analyst—The City Analyst, City Laboratories, Mou Pleasant, Liverpool 3 (May 28).

Lecturer in Bacteriology, and a Lecturer or Assista Lecturer in the Department of Biochemistry—The Registr The University, Sheffield (May 28).

Assistant Lecturer in Physics—The Principal, Royal Hollow College, Englefield Green, Surrey (May 28).

Senior Lecturer in Psychology (General Psychology with spec emphasis on Educational Psychology) in the University of Melbour —The Secretary, Association of Universities of the British Commo wealth, 5 Gordon Square, London, W.C.1 (May 30).

Lecturer in Biochemistry—The Secretary, Royal (Dick) Vet inary College, Summerhall, Edinburgh 9 (May 31).

Director of the National Institute of Oceanography—T Secretary, Civil Service Commission, Scientific Branch, 27 Grosven Square, London, W.1, quoting No. 2549 (June 3).

Lecturer (male) in Botany in the Imperial College of Trop Agriculture, Trinidad—The Secretary, Imperial College of Trop Agriculture, 40 Norfolk Street, London, W.C.2 (June 30).

Macleay Bacteriologist—The Secretary, Linnean Society of Ne South Wales, Science House, Gloucester Street, Sydney, N.S.W Australia (June 30).

Laboratory Technicians in the Departments of (*a*) B chemistry, (*b*) Biological Chemotherapy and Tropical Medicin and (*c*) Bacteriology with Immunology—The Administrat Officer, National Institute for Medical Research, Hampstead, Lond N.W.3.

Research Physicist to undertake investigations on semi-conduct materials—The Professor of Physics, The University, Reading.

Assistant Teacher in the Chemistry Department, to tea Physics and Mathematics, in the Bolton Municipal Technical College The Chief Education Officer, Education Offices, Nelson Square, Bolt

Lecturer in Mechanical Engineering—The Clerk to the Gove ing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Entomologists (*a*) with a special interest in and knowledge the Hymenoptera, to undertake determinations and some systema revisionary work in that Order, particularly in the parasitic grou (*b*) with a special interest in and general knowledge of the Coleopte to undertake determinations and possibly later some systematic visionary work in that Order, (*c*) with a wide general knowledge entomology with a special interest in the bibliographical and inform tion aspect of the subject—The Director, Commonwealth Institute Entomology, 41 Queen's Gate, London, S.W.7.

Metallurgist in the Mines Division of the Lands, Mines a Surveys Department, Kenya—The Director of Recruitment (Colon Service), Sanctuary Buildings, Great Smith Street, London, S.W.1.

Laboratory Assistant (post-matriculation work in biology a chemistry minimum qualification)—The Headmistress, Coun Grammar School for Girls, Coolinge Lane, Folkestone.

Chemists and Physicists—The Director, Paint Research Statio Waldegrave Road, Teddington, Middx.

Senior Officer to supervise and develop the work in the Chemic Section, a Secretary to group of Committees dealing wi Mechanical Engineering subjects, a Secretary to group of Committe dealing with Radio subjects, and a Committee Secretary (male female) with general technical background—The Director, Briti Standards Institution, 28 Victoria Street, London, S.W.1, endors 'Technical Assistant'.

Laboratory Assistant (mainly for work in Electrical and Mecha ical Engineering laboratories)—The Principal, Maidstone Techni College, Tonbridge Road, Maidstone, Kent.

Graduate (preferably with research experience in biochemistry chemistry) to assist in investigations on intermediary metabolism The House Governor and Secretary, Royal Cancer Hospital, Fulha Road, London, S.W.3.

BRITISH COLONIAL GEOLOGICAL SURVEYS

PLANNED co-operation in the development of backward areas may well serve modern needs better than unrestricted and often wasteful competition; and this applies particularly in connexion with the mineral development of vast, virtually unexplored regions such as are presented by the continent of Africa. The recent proposal to supplement various Colonial Surveys, particularly in Africa, by American geologists, therefore, deserves careful consideration. In commercial work there has at times been considerable collaboration between geologists of all English-speaking countries, as evidenced during the copper development period in Northern Rhodesia, when millions of subscribed capital were spent on exploration by the companies concerned. The results that they obtained were not, however, generally made public; there is no published map of the special areas which were explored in that large territory.

The present proposal takes for granted that there is, and will be for some time, a serious shortage of geologists in Great Britain and the Dominions. As to the competence of the geologists of the British Commonwealth there can be no doubt; the Dominions and Colonies have been well served indeed by their official Surveys, wherever these exist and where they have been adequately supported. The tempo is now to increase; the support to be given them will be greater.

Many of the problems of geological survey, especially in Africa, are not such as would confront a commercial company. Their study may not lead to immediate results. The work of a geological survey is never finished. There is not merely the question of an intensive search for economic minerals. There are problems of soil erosion, water supply, irrigation, structures, structural materials and hydro-electric problems, the location of land for agricultural needs, and the supply of essential mineral fertilizers. Where minerals are concerned, one is not necessarily considering the immediate exploitation of an economic asset. It is the function of a State Geological Survey to study what may be called 'strategic reserves' of minerals which may not be capable of being put to economic use for some time, or which, for reasons of national policy, it may not be desirable to disperse or even to discuss publicly. This has not infrequently led to conflict of opinion between big business interests, which generally have a relatively narrow outlook, and Government officers, whose duty it is to take a longer and more impartial view.

There are therefore some very practical questions to be answered before embarking on the wholesale recruitment of geologists from the United States for work on Colonial Surveys. Such survey work is a long-term operation for Governments, not short-period research for a company. Will American colleagues working with a Colonial Survey in, say, Africa, be content to abide by the rules of an alien service? Will they be ready to lease or lend their national loyalty ? Will they be content to spend long periods of their lives away from their own land, where opportunity and prosperity are still within reach of many ? If not, what is to compensate for breaks in continuity of their work ? Africa is not to be learned in a day.

Remuneration for such services in the United States is on a much higher scale than is customary in British Colonial or Dominion Geological Surveys. If, in the latter, it had been more generous in the past, there would no doubt be a less obvious shortage of British geologists now. Is it intended to scale up the rate of pay in these services, or are American geologists to receive an additional subsidy from their own or other Government concerned ? The position may perhaps be summarized in the reply of at least one Geological Survey to a question regarding aid from the Office of European Economic Co-operation, in which the services of American experts were offered. In effect, it said that the needs and proper programme of that Survey had been painfully apparent for many years; what was required was money to carry them out.

Given adequate funds and sympathetic support, it should not take too long to attract and train men from the Commonwealth and Great Britain to their own geological services. For long-term work, as opposed to an immediate need, this is what is required ; and the United States could render great service by helping in the part-training of such men in their own institutions and methods. It would be better to benefit by American generosity in this way than to subsidize American geologists to spend short periods under British administration, perhaps in competition with their fellow-professionals. True co-operation should not, in Kipling's telling phrase, become involved in "the business end of the American invasion".

Industrial competition within the United States has caused, and is still causing, an excessive waste and dispersal of irrecoverable raw materials. Any new discoveries of minerals in other lands should not be drawn into the mill of American productivity before a reasonable brake and limit has been set on the expenditure of such materials. This can only, and must ultimately, be attained by international agreement.

The development of backward areas through the collaboration of American personnel must needs bring with it some preference for American machinery and equipment, and some priority in the allocation to the United States of the raw materials produced. The law "to him that hath shall be given" has a sound philosophical basis, just as the problems of the concentration and dispersal of matter have their counterpart in the second law of thermodynamics. The need of the world to-day is that there should not be too much concentration of any one thing in one particular area, while providing for an adequate supply everywhere. If collaboration has this end in view, it is to be welcomed. Is it invidious to suggest that, concurrently with the development of backward areas, and the relieving of distressed ones, a modest form of rationing of some raw materials should be accepted in the New World ?

THE NURTURE OF RESEARCH

The Genius of Industrial Research

By D. H. Killeffer. Pp. ix+263. (New York
Reinhold Publishing Corporation ; London : Cha
man and Hall, Ltd., 1948.) 27*s.* net.

IN the ever-growing literature dealing with industri
research, comparatively little attention has bee
given to the mental characteristics needed for researc
work and whether the training given at universiti
and technical colleges tends to develop adequatel
these qualities. In "Glances at Industrial Research"
E. R. Weidlein and W. A. Hamor look beyond th
walls of the Mellon Institute to the broader pr
fessional aspects of industrial research. These prol
lems are briefly considered by Dr. D. W. Hill
"Co-operative Industrial Research" ; but were virtu
ally ignored by Sir Frank Heath and A. L. Hetherin
ton in "Industrial Research and Development".
more adequate discussion is to be found in "Th
Future of Industrial Research", issued four years ag
by the Standard Oil Development Co. ; but apa
from highly suggestive passages in Col. L. E. Simon
"German Research in World War II", it is to th
scientific and technical periodicals that we must loo
for the more penetrating discussions of the qualiti
required in industrial research and the methods b
which they are best fostered. Some of the post-w
reports, like Dr. Vannevar Bush's "Science—th
Endless Frontier" and that of the Barlow Committe
on Scientific Staff, or statements from Nuffiel
College, have made some contribution ; but by an
large the most useful and fundamental contributio
are widely scattered and probably not easily assemble

Clearly the subject is one that demands som
consideration at the present time, when the relati
contribution of the technical colleges and of th
universities is in debate, and Sir Lawrence Bragg
address on "The Standards of Advanced Studies ar
Research in Science and Technology", recently pu
lished in the *Universities' Quarterly*, will doubtle
provoke some discussion on the issues which
clarifies. In the present volume, Mr. Killeffer's trea
ment is too superficial to make any real contributio
to elucidating the qualities which are essential
success in industrial research or the way in whic
they are best fostered. His book is a treatise c
the technique of research and some factors tha
determine success in industrial research, rather tha
a discussion of the genius or real nature of research
it indicates to the undergraduate the range of exper
ence he may encounter and some of the techniqu
he should develop if he enters on a career in industri
research, rather than suggests to a teacher the wa
in which the inherent abilities of a student may be
be nurtured for success in that field.

Mr. Killeffer's diffidence over the term 'geniu
indicates that he is half aware that his title is il
chosen. He does not distinguish very clearly betwee
fundamental, or academic, research and industri
research, and some of his categories of the latter ad
nothing to his argument. This would be less importa
if Mr. Killeffer recognized that the creative mind
which are always rare, are required in both academ
and industrial research. It is from them that th
real advances come, nor are such men and wome
always the eccentrics that Mr. Killeffer implies. Oft
they take their place in a team, whether as units
as leaders, quite as harmoniously as their less talent
colleagues.

Success in industrial research, in Mr. Killeffer's view, appears to be mainly a matter of methodical thinking, systematic organisation and wise choice of objectives rather than one of inspiration. His prime purpose in writing the book is, by analysing the methods of thought and procedure followed by some outstanding investigators, to display principles that may guide the young investigator to a clearer understanding of the nature of research, and increase his competence. He has accordingly compiled a thoroughly representative collection of first-hand accounts of such work, largely from addresses of Perkin medallists and the like, including such pre-eminent investigators as Langmuir, Genslager, Midgley, Cottrell, Twitchell, Sabatier and R. Williams, and ranging over such varied fields as gas-filled lamps, rubber accelerators, refrigerants, high-octane petrol, synthetic rubber, vitamin B_1, to J. E. Teeple's work on potash recovery and E. Weston's on nickel-plating. The result should have been a source book of industrial research which could take a worthy place beside other volumes in the well-known series published by the McGraw-Hill Book Co.

The accounts, though full, are, however, abridged and are interspersed with comments or explanations by Mr. Killeffer himself. Good as some of this material is, Mr. Killeffer has not left himself the space to deal really effectively with such matters as pilot-plant development, report writing, patents and the evaluation of results, on each of which he has short chapters. While abridgment has robbed the records of something of the effect of full contact with original minds, Mr. Killeffer has not succeeded in making good the defect himself, as is well shown by his chapter, "Thinking out the Problem", in which the whole question of scientific method is dismissed too cursorily; and little awareness of the major contributions to modern thought on that subject is revealed. His own contribution is less than that of F. R. Bichowsky in an earlier book, "Industrial Research".

How great an opportunity has been missed by thus falling between two stools may best be realized by comparing the book not merely with the 'source-book' series already mentioned and such outstanding lectures as F. R. Japp's Kekulé Memorial Lecture, or the Hoffman Memorial Lectures of Lord Playfair, W. H. Perkin or H. E. Armstrong, but also with autobiographies or biographies of the quality of Sir J. J. Thomson's "Recollections and Reflections" or Dr. A. S. Eve's "Rutherford". If Mr. Killeffer had learned the lessons of such works, the present volume might well have taken different shape.

For the rest, the book firmly assaults the popular myth that the processes of scientific and technical advance are mysterious and akin to the methods of the magician. Mr. Killeffer says surprisingly little about the qualities making for successful team-work which have been emphasized in such war-time achievements as radar, atomic energy, penicillin and the like. He recognizes the value of imagination and the ability to see beyond mere surface indications; but his stress is laid, in the main, on those qualities of intelligence and orderly thought and the acquisition of techniques which can be developed by efficient and thorough training as the indispensable minimum for success in industrial research. Without these, or without the help of other workers who possess them, genius itself may be ineffective in industry.

Mr. Killeffer's book may provoke some profitable discussion, and he may have blazed a trail for a more adequate and inspiring source-book. Whether university professors, even in the United States, will find that they can use the book for educational purposes remains to be seen. Mr. Killeffer has at least opened up the subject further; but it is to be hoped that those who follow in his trail will avoid the time-wasting practice of relegating all bibliographical references to the end of the book, instead of placing them where they are normally sought and found by the reader.

R. BRIGHTMAN

DISCUSSION ON ISOTOPES

Institut International de Chimie Solvay: Rapports et discussions sur les isotopes

Septième Conseil de Chimie tenu à l'Université de Bruxelles, du 22 au 27 septembre 1947. Pp. iii+411. (Bruxelles: R. Stoop, 1948.) N.p.

THE first Chemical Congress of the Solvay Institute took place in Brussels in 1922; ensuing Congresses were held at regular intervals of three years until 1937. At each of them, men of science from various countries presented authoritative reviews on topical subjects, and the printed reports of these meetings are still a valuable source of information. It was, therefore, very welcome news when it became known that, after the war-time interruption, the Seventh Chemical Solvay Congress would be arranged in Brussels in the autumn of 1947, under the chairmanship of Prof. P. Karrer (Zurich). Its subject was "Les Isotopes".

The "Reports and Discussions" of the Congress have now been published in a stately volume of more than 400 pages. As was to be expected from the general title chosen, very different sides of the question of isotopes have been under review at Brussels. Prof. F. Joliot (Paris) dealt with "Modes de formation, constitutions et filiations des isotopes, notamment des isotopes artificiels"; Prof. K. T. Bainbridge (Harvard) with "Some Results of Mass-Spectrum Analysis". There followed two papers on the spectroscopy of isotopes; Prof. C. K. Ingold (London) gave a résumé on "Isotopes in the Spectroscopy of Polyatomic Molecules with Special Reference to the Benzene Molecule", and Prof. M. de Hemptinne (Louvain) spoke on "Les isotopes comme moyen d'investigation des spectres de bandes". The next two lecturers paid attention to the chemical technique, Prof. F. A. Paneth (Durham) discussing "The Preparation of Radioactive Tracers", and Prof. A. Langseth (Copenhagen) "The Preparation of Organic Deuterium Compounds". The last three reports were almost exclusively devoted to biological uses of the tracer technique. Prof. G. de Hevesy (Copenhagen) described the "Application of Labelled Phosphorus", Prof. M. Calvin (Berkeley, Cal.) "Radiocarbon and its Application in Chemistry and Biology", and Prof. D. Rittenberg (New York) "The Use of ^{15}N and D for the Study of Chemical Processes in the Living Cell".

This enumeration of the titles will provide some means of gauging the wealth of information contained in the volume, too rich indeed to be briefly abstracted. It is to be added that a Solvay Congress, with its limited number of specialist members and generous allowance of time, provides a particularly good setting for fruitful discussions; in these not only "les membres rapporteurs", the principal speakers, participate, but also the scientific secretaries of the Solvay Foundation and a dozen or so invited guests. Their joint efforts represent a scientific contribution by no means less valuable than the introductory reports, and Prof. J. Timmermans, the secretary of the scientific committee, and his helpers are to be congratulated especially on the excellent way in which the discussions of 1947 have been seen through the press—no easy task, since the speakers dispersed immediately after the Congress was over, and their scattered notes had to be co-ordinated. That the two official languages of the Congress, French and English, have been printed equally well is perhaps not more than most people are inclined to take for granted in a Brussels publication.

F. A. P.

ROCKET PROPULSION: PAST, PRESENT AND FUTURE

Rockets and Space Travel

The Future of Flight beyond the Stratosphere. By Willy Ley. Pp. viii+374+14 plates. (London: Chapman and Hall, Ltd., 1948.) 18*s*. net.

SINCE the earliest times, man has dreamed of the possibility of leaving this planet to visit the heavenly bodies, and much has been written around this theme, ranging from the satirical and fantastic to the serious and scientific. This book is an encyclopædic survey in a readable and untechnical style of every aspect of the subject.

The author begins by discussing the numerous imaginative stories of journeys to the moon and stars which have been written throughout the ages. Of these, the best known are probably Lucian's "Vera Historia", Kepler's "Somnium", Cyrano de Bergerac's "Voyage dans la Lune", and the novels of Jules Verne and H. G. Wells. The development of rockets is then described. It appears that the earliest mention of rockets which can be traced is contained in a Chinese chronicle which records their use at the siege of Pien-king in A.D. 1232. Soon after that date they were used by the Arabs and in Europe. At the end of the eighteenth century, Hydar Ali and his son Tippoo Sultan successfully employed them against the British in India, and this led to the considerable improvements in rocket design and performance made by Sir William Congreve, and to the establishment of the British Rocket Corps, which distinguished itself on the Continent in the early part of the nineteenth century. From about 1850 until the First World War, rockets as a weapon of war suffered a decline because of the great advances made in artillery.

The tide then turned, and between the two Wars considerable progress in rocket development was made, chiefly in America by Goddard and in Germany by the Verein für Raumschiffahrt, of which the author was vice-president. He gives a most interesting first-hand, though probably not entirely unbiased, account of the fortunes of this Society and of the personalities of its leading members, such as Oberth, Valier and Hohmann, and of others, such as von Opal and Ganswindt. During the recent War, rocket development advanced at an extremely rapid pace, and the book contains chapters in which the chief rockets used by the Americans, British and Germans are described.

For Mr. W. Ley the chief interest of rockets lies in the possibility of their use as a means of escaping from the earth's gravitational field, and he devote a considerable part of his book to a discussion of space-travel and its problems. The theoretical work of Hohmann and others is described, and numerous diagrams are given in order to illustrate the best and most economical routes to and round the moon and planets, the techniques of landing and other point of astro-navigation. Figures and tables based on various fuels and propellant-mass ratios are quoted and other problems, such as the effect of gravity and acceleration on the human body, are not neglected. One may not share Mr. Ley's idealism and enthusiasm; but one cannot help admiring the thoroughness with which he investigates, and generally overcomes, all the objections and difficultie which arise.

The volume is exceedingly well documented throughout; perhaps one of its most valuable part is the extensive bibliography of books and pamphlets in which are listed about 150 works in English French, Russian and Italian, ranging from th technical and mathematical to the historical and fictional.

R. A. RANKIN

A MODERN COUNTY FLORA

A Geographical Handbook of the Dorset Flora

By Prof. Ronald Good; including a Chapter on th Soils of Dorset, by K. L. Robinson. Pp. xi+255 (Dorchester: Dorset Natural History and Archæological Society, 1948.) 20*s*.

THE facts of distribution of the flowering plant of Britain are to be found in a long series o county floras which we owe to the flair and enthusiasm of the amateur field botanist. These facts have been the material for wider speculation on and more detailed study of the factors determining the origin and controlling the distribution of the flora. Th names of Forbes, Watson, Stapf, Matthews and Salisbury may remind us of the interest of such contributions. Prof. R. Good's book is unique in combining the facts of the typical county flora with a consideration of general and special problems o distribution.

Its predecessor, Mansel-Pleydell's "Flora of Dorsetshire", was published in 1895 and is a good example of its kind. It is interesting to compare it with Prof. Good's "Handbook". In the earlier book, preliminary matter runs to 37 pages and 345 are given to the lists of plants. In the later, the lists of plants take jus one half of 255 pages. In both there is a short account of topography and geology. Prof. Good also deals with climate and includes a useful and modern account of soil types and distribution from the pen of K. L. Robinson. Mansel-Pleydell gives some tables comparing the Dorset flora with that of neighbouring regions. Prof. Good has written a lucid account of the origin of various groups of native plants and discusses the status of 47 adventive species.

But the most interesting part of the work, and that which is entirely fresh, is a detailed account of the distribution of plants within the county. There is an introduction on general principles and a brief section on the climatic factor. Climate seems to be the major factor controlling the distribution of about a hundred species. For most plants, however, edaphic factors are decisive, and the effects of these are dealt with in great detail. Finally, there is a chapter on plants the distribution of which cannot be related to any one dominating factor, and, here, suggestion is accompanied by indications of problems needing further research. The general treatment is throughout pointed by reference to a selection of individual species, and is illustrated by thirty maps. Readers of Prof. Good's "Geography of the Flowering Plants" will recognize in all this the foundation of chapter 13 of that work.

It is clear that this admirable treatment could not have been based on the older type of record. It has been made possible only because the author himself undertook a systematic survey which lasted over nine seasons. In the course of this the occurrence of more than 600 species was recorded for 7,500 stands —an average of seven to nine stands to the square mile. This was a great task, and its effects are seen in the number and spacing of the dots on the distribution maps. From all this has come the present book. It includes the customary plant lists. It is also an original and valuable contribution to plant geography and a signpost to new pastures for the ield botanist.

M. Skene

PROGRESS IN BIOCHEMISTRY

Annual Review of Biochemistry

Edited by J. Murray Luck, Hubert S. Loring and Gordon Mackinney. Vol. 17. Pp. ix+801. (Stanford, Calif.: Annual Reviews, Inc.; London: H. K. Lewis and Co., Ltd., 1948.) 6 dollars.

WHEN the "Annual Review of Biochemistry" first appeared in 1932 it was born almost at its present size, for the first volume, of 724 pages, was little smaller than the latest. Nourished by an increasing diet of publications, the "Review" might have grown alarmingly; but, partly by feeding portions to the newer "Annual Reviews" of physiology and microbiology, the editors have successfully kept it down. The exuberance of biochemistry is such, however, that further procrustean treatment is necessary, and, in 1950, plant material will be removed into a new "Annual Review of Plant Physiology". The wisdom of this decision is perhaps confirmed by the article on plant hormones in the present volume, which contains quite a long section on the control of weeds.

The service rendered by the "Review" to biochemistry is widely appreciated and frequently acknowledged; nevertheless, the present writer cannot forgo the privilege of offering his own grateful thanks. The function of the reviewer of these volumes is limited; he is in danger of preaching to the converted; and he can serve best by trying to attract the attention of uninitiated workers in related fields. He can also indicate what, in his opinion, are the strengths and weaknesses of the volume under review. This volume follows the familiar pattern, with articles on enzymes and on the chemistry and metabolism of the fundamental biochemical substances, with the addition of chapters on more specialized topics. This time the latter include the chemistry of the immunopolysaccharides, X-ray crystallographic studies of compounds of biochemical interest (showing the help given in the elucidation of the structure of penicillin), clinical applications of biochemistry (serum potassium, phosphatases, blood iodine, liver function), metabolism of drugs and toxic substances, clinical aspects of vitamins, biochemistry of carcinogenesis (including the metabolism of carcinogenic substances, factors influencing carcinogenesis and tissue changes in neoplasia), terpenes (especially of the genus *Pinus*), alkaloids, photosynthesis, mineral nutrition of plants, plant hormones, chemistry of penicillin (a 'brief' summary of 41 pages and 216 references), ruminant digestion (tracing the formation and utilization of the volatile fatty acids) and physiological aspects of genetics (featuring the obliging *Neurospora*, viruses and many other organisms, including man). Despite the existence of the "Annual Review of Microbiology", there is an article on bacterial metabolism, a welcome provision for macrobiological chemists wishing to keep in touch. Lack of space prevents the present writer from describing the contents of all these articles, but the titles indicate the importance and fascinating nature of the subjects reviewed.

Reduction in size could be accomplished by stricter editing and control of the scope of each review. Thus, xanthine oxidase is considered in "Nonoxidative Enzymes" as well as in "Biological Oxidations and Reductions"; catalase is discussed in two articles and acetate metabolism in four. "Clinical Aspects of Vitamins" contains matter and formulæ more suitable for a text-book, shows the structural formula of pteroylglutamic acid twice, and contains such statements as, "We must know more of the mechanism of the carcinogenic action of all the factors promoting and retarding the production of tumors", and "In deficiency of vitamin A, certain specific pathologic changes are observed in the epithelial structures. Eventually they give rise to what can be termed vitamin A deficiency."

The subject index is regrettably inadequate. Whereas the author index extends to thirty three-column pages, the subject index consists of only nineteen two-column pages. It occupied fifty pages in 1945. A really comprehensive subject index would add enormously to the value of the work, and if it involved delay in publication, this would be justified. Few textual errors were noted, but "Staphlocoagulase [*sic*], an enzyme from pathogenic streptococci" (p. 38), one misprint on p. 21, two on p. 35 and one on p. 209 may be cited.

Perhaps the greatest problem of the contributors is that of welding brief references to large numbers of papers into readable accounts. This year they have been particularly successful. In addition, combining wise saws with their modern examples, many have made profound remarks designed to clear up current muddled thinking, or have warned against the abuse of modern techniques by the unskilled and the unwary. A discussion of nomenclature is a valuable feature of at least two articles.

Finally, the deft touch is not lacking; we are informed that the blood group enzyme acts not only on Negro erythrocytes but also on those of diseased Caucasians; while the statement that "tocopheryl phosphate removes the calcium that activates the nucleotidase that destroys the coenzyme that catalyzes the oxidation of malate to oxaloacetate", although it may have to be modified slightly in view of later work by Pardee and Potter, brings back happy memories of a childhood spent when life, and biochemistry, were so much simpler.

G. D. Greville

Elsevier's Encyclopædia of Organic Chemistry

Edited by R. Radt. Series 3: Carboisocyclic Condensed Compounds. Vol. 12*B*: Naphthalene; *A*. Compounds containing One Naphthalene Nucleus; Hydrocarbons and Halogen Compounds. Pp. xxx+344+22. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1948.) To subscribers to whole work, £6 5*s*. 0*d*.

THIS is actually the first part of vol. 12*B*, for it deals only with hydrocarbons of the naphthalene series, their hydrides and the halogen compounds. The much larger number of other derivatives, together with compounds containing more than one naphthalene nucleus, will presumably form the subject of one or more further parts. Series 3 of the 'Encyclopædia' will then be complete, for vols. 12*A*, 13 and 14 have already been issued (for a general description of the whole project, see *Nature*, 161, 415; 1948). The present volume maintains the standard of excellence of its predecessors; but the rate of progress is behind schedule, and considerable acceleration will be needed if the work is to constitute an up-to-date compendium of organic chemical compounds.

It is stated in the preface that references up to the end of 1944 have been included in this volume, and, as far as the reviewer has been able to determine, the bibliography is complete. More important publications of 1945–47 are also noted. In addition to its attractive lay-out, the book has many pleasing features, including the useful summaries of data given in many tables, the generous use of neatly printed structural formulæ to illustrate reactions, and the sure chemical instinct exemplified by a number of cogent editorial comments. The sections dealing with the more important compounds, such as naphthalene and its monomethyl and monohalogeno derivatives, tetralin, decalin, cadinene and selinene, form readable and informative articles. The volume may be commended to the attention of all organic chemists, whatever their specific fields of interest.

J. W. COOK

Géométrie descriptive à quatre dimensions

Par J. Maurin. Livre 1: Figures du premier degré. Chapitres 1, 2, 3: Définitions, positions, intersections. Pp. 38. (Paris: Libr. Gauthier-Villars, 1948.) 200 francs.

THE reviewer approached this volume in a mood of reflexion as to the proper place in the general scheme of geometrical study for four-dimensional geometry. His own introduction to the concepts of geometry of more than three dimensions was through the excellent volumes of M. Jonffert ("Traité Elémentaire de Géométrie à Quatre Dimensions", 1903; and "Mélanges de Géométrie à Quatre Dimensions", 1907). Though interested, he felt an acute disappointment in the natural limitations therein, which was not overcome until, long after, Bertini's work came to his hands. He therefore read M. J. Maurin's volume with a prejudice that, for the geometer, the general n-dimensional case should be first studied and the four-dimensional enlarged upon later.

M. Maurin, in pointing out the peculiar importance of four-dimensional geometry in the study of some mechanical phenomena, makes a strong case for its independent consideration. The present volume is limited to definitions and the study of the intersections of lines and of planes. His method of presentation is an extension of the method of Monge and is amply illustrated by diagrams which occupy half volume. The range is too restricted for the rea to obtain any estimate of the ultimate value of method of approach, but the author suggests t interesting developments will be found in la volumes, which are much looked forward to. In vi of his special plea for the importance of fo dimensional study it would have been well if a lit more space had been devoted in the introduct pages to initial ideas; the first few paragraphs so condensed that the student with no previ knowledge will find them insufficient for his und standing.

H. GWYNEDD GREEN

X-Ray Optics

The Diffraction of X-Rays by Finite and Imperf Crystals. By A. J. C. Wilson. (Methuen's Monograp on Physical Subjects.) Pp. vii+127. (Londo Methuen and Co., Ltd., 1949.) 6*s*. net.

THIS work fully maintains the standard that now expected from this well-known series. T author has set himself well-defined limits, has stat these clearly in the preface, and has treated t subject-matter within these limits in a workmanli fashion. It is unfortunate, therefore, that the ma title of the book is deceptive, and that it has to qualified by a sub-title; a book on X-ray opt should have image formation as its main conten but this subject is not dealt with at all in this boo The author justifies this omission on the groun that crystal-structure determination is closer chemistry than to physics. The reviewer does n agree with this; the results are certainly of chemi interest, but the *methods* are essentially physical.

Apart from the title, however, there is little th one can criticize. The author has collected togeth a variety of problems in the diffraction of X-rays imperfect crystals and has shown how they can treated mathematically. He has taken pains introduce the subject gradually—perhaps too grad ally for those who are able to master the la chapters—and therefore almost everybody will ga something from the book. In addition, the style pleasingly informal. The book can be confiden recommended to those interested in X-ray diffracti particularly to those concerned with the finer detai

The Way of a Plant in Field and Garden

By Gareth H. Browning. Pp. x+141+7 plate (London: Rockliff Publishing Corporation, Lt 1949.) 8*s*. 6*d*. net.

MR. GARETH BROWNING, author of seve works on popular natural history, has writt another little book which seeks to explain the fun tions of the flowering plant in such a way that will be scientifically correct and also intelligible the general reader. From both points of view he h achieved his object, and his book will be of value the non-specialist interested in agriculture, horticult or the natural history of plants. Whether the bo will appeal to them sufficiently to make them wa to buy it is another matter. Authors of success books on popular subjects to-day realize the val of visual appeal and, generally speaking, have set high standard in the range and quality of the pai ings, photographs and diagrams of the illustratio to their books. The seven coloured photographs a thirteen line-drawings in "The Way of a Plant" a not enough, neither are they of a high standard.

EDWARD JENNER, BENJAMIN WATERHOUSE, AND THE INTRODUCTION OF VACCINATION INTO THE UNITED STATES

By DR. E. ASHWORTH UNDERWOOD
The Wellcome Historical Medical Museum

THE two-hundredth anniversary of the birth of Edward Jenner, the discoverer of vaccination, was celebrated on Tuesday, May 17, by functions in many places, but notably at Berkeley, Glos, his birthplace, at the Royal College of Physicians, the Royal College of Surgeons—where Sir Edward Mellanby gave an address—and the Wellcome Historical Medical Museum. Much of what can be said—within the limits of an article—on Jenner's life and work has already been said. This present tribute to a man to whom mankind owes so much will therefore be concerned mainly with those aspects of his life and work which have some bearing on the introduction of vaccination into the United States. Although these events are well known in America, the important work which Benjamin Waterhouse did is not fully appreciated in Britain. In this brief article, it is impossible to avoid ground which has already been covered in certain American journals.

Jenner's Early Life

Edward Jenner was born at the Old Vicarage, Berkeley, on May 17, 1749. His father was vicar of Berkeley, and his elder brother Stephen was also in Holy Orders. Edward was apprenticed to a surgeon at Sodbury when he was thirteen, and for the next eight years he had excellent practical experience. When he was twenty-one he became a resident house-pupil in the London house of John Hunter, and during the two years while he was a pupil, a friendship developed between Jenner and Hunter, twenty-one years his senior. In 1772, when Jenner seemed set for a London career, he succumbed to the lure of his native county—he was essentially a countryman—and returned to practise at Berkeley. There, with brief interludes, he remained the rest of his life. Until Hunter's death in 1793, he and Jenner corresponded regularly, and the elder man constantly encouraged the younger in natural history pursuits, and as constantly requested specimens of the most varied kind. It was early in this correspondence that Hunter gave Jenner the famous advice: "But why think, why not try the experiment ?"[1]. This encouragement resulted ultimately in Jenner's admirable paper on the habits of the cuckoo[2], in which he described the method whereby the young cuckoo clears the nest of its foster-parent. Often discredited, this work has been completely vindicated in recent years.

Jenner and the Concept of Vaccination

Baron says[3]—probably with truth—that the idea that cowpox could confer protection against subsequent infection with smallpox first entered Jenner's mind when, as an apprentice at Sodbury, he heard a young countrywoman say when smallpox was mentioned in her presence: "I cannot take that disease, for I have had cow-pox". He certainly reflected on this statement, and in later years he was impressed by the fact that, when he was inoculating smallpox matter for 'protective' purposes, the operation was unsuccessful in those who had previously had cowpox. The principle of inoculation was that the individual was given what was hoped would be a mild attack at a convenient time, and was thereby protected against a natural attack of the disease, which was often severe and loathsome, and fatal in as many as 50 per cent of the cases. This practice was introduced by Timoni (1714) and Pylarini (1715); but the effective agent in popularizing it was Lady Mary Wortley Montagu (1721). By Jenner's day it was a common practice. It was a bad method, since the resulting disease was often not mild, and sometimes caused death. Further, each inoculated person acted as a focus for the dissemination of true smallpox.

To return to Jenner. He was well aware of the fact that cowpox was found only in certain counties in Britain, and moreover was present only at intervals. Smallpox, on the other hand, was possibly worst in London, where at that time it was causing a rough average of two thousand deaths annually. Natural cowpox would therefore not be very effective in preventing smallpox in a crowded city where only a few people handled cows. On the other hand, if he could show that cowpox occurring naturally in man could then be transmitted from one individual to another without losing its power to protect against smallpox, there would be no limit to the number of individuals who could be protected. These were the two propositions which Jenner set out to test experimentally, and the results were set out in his "Inquiry into the Causes and Effects of the Variolæ Vaccinæ, a disease discovered in some of the Western Counties of England . . . and known by the name of the Cow Pox". This small book was published in the summer of 1798, and two further editions were published later. I have given elsewhere[4] a critical statement of the genesis and reasoning of this book, and it must suffice to state here that, though the cases were few, they did form a *prima facie* case.

Events Following Publication

After publication of the "Inquiry", Jenner went to London to seek volunteers for vaccination; but though he stayed there three months he was unsuccessful. Vaccination in London was popularized by Henry Cline, who started with some lymph which Jenner gave him; by Dr. Woodville, of the Smallpox Hospital, and by Dr. George Pearson. It was soon evident that Woodville and Pearson were planning to take the whole credit for the introduction of vaccination; but Jenner's equanimity enabled him to stem the tide. Vaccination was soon widely practised in Britain. Various contretemps occurred, many of which Jenner had foreseen. In May 1799, De Carro introduced vaccination to Vienna[5], and German cities soon followed. In January 1800, the "Inquiry" was translated into French, and was published in Paris soon afterwards[6]. It should be remembered that Britain was then at war with France—which explains the delay. Vaccination spread from France to Spain during the latter part of 1800, and it was soon widely practised in most European countries. From the very time when the announcement of the discovery was first made, the emphasis was always on *free* vaccination. By the end of 1799 various attempts had been made in provincial cities to form "institutions for gratuitous inoculation", that is, vaccination[7]. In London, Pearson formed a vaccine board, which was to carry out free vaccination. As early as September 1798, Jenner had been pressed by Henry Cline and Sir Walter Farquhar to take a house in Grosvenor Square; they promised him £10,000 per annum. He declined, and in a letter to a friend at this time he wrote:

"Shall I, who even in the morning of my days sought the lowly and sequestered paths of life, the valley, and not the mountain; shall I, now my evening is fast approaching, hold myself up as an object for fortune and for fame?—Admitting it as a certainty that I obtain both, what stock should I add to my little fund of happiness?

"My fortune, with what flows in from my profession, is sufficient to gratify my wishes; indeed so limited is my ambition and that of my nearest connexions, that were I precluded from future practice I should be enabled to obtain all I want. And as for fame what is it? a gilded butt, for ever pierced with the arrows of malignancy"[8].

Introduction of Vaccination to the United States

The fact that vaccination was introduced into the United States by Benjamin Waterhouse is stated briefly in all works dealing with the history of vaccination. Baron, writing in 1838, had quite a lot to say about the event. But though the work of Waterhouse was recognized in most parts of America and abroad, in Boston, where he spent all his active life, he was half-forgotten. This was due to the fact that he was never popular with the other members of the profession at Boston and Harvard. He was a Quaker, an active controversialist, an opponent of the political party in power, and at heart a scientific man who had perforce to practise medicine. It was the publication of the paper "Waterhouse, the Jenner of America", by William H. Welch, in 1885, that really placed him in his proper place[9]. Welch gives all the relative facts, but for a true appreciation of the various difficulties encountered we must go to Waterhouse's own publications on vaccination[10,11]. These, like other early vaccination tracts, are now very rare. First let us look at the man.

Dr. Benjamin Waterhouse

Benjamin Waterhouse was born in Newport, Rhode Island, on March 4, 1754. His mother was a niece of John Fothergill, the famous London physician, and in due course Waterhouse studied under Fothergill. He also took courses at Edinburgh and for four years at Leyden, where he graduated in 1781. After assisting his uncle for a time he returned to practise in Newport, Rhode Island, in June 1782. A medical college was then being inaugurated in association with Harvard College, and Waterhouse was invited to take the chair of the theory and practice of medicine. He was the first in America to give a systematic course of instruction in botany and mineralogy, and he founded the Botanical Gardens at Cambridge, Mass., and the collection of mineralogy at Harvard. Despite these advances, his unpopularity and the acrimonious disputes in which he was involved led to him being deprived of his chair in 1812. He died at Cambridge on October 2, 1846.

Benjamin Waterhouse
From Lettsom's "Hints", vol. 3 (1801)

In the beginning of 1799 Waterhouse received from his friend John Coakley Lettsom in London a copy of Jenner's "Inquiry". Waterhouse says that the disease cowpox was totally unknown in that part of the world. He goes on: "On perusing this work, I was struck with the unspeakable advantages that might accrue to this country, and indeed to the human race at large, from the discovery of a mild distemper that would ever after secure the constitution from that terrible scourge, the small-pox"[10]. Soon after, he received a copy of George Pearson's book on vaccination, and he sent to the *Columbian Centinel* of March 12, 1799, a short account of the method under the title "Something Curious in the Medical Line". He reprints this article in the first part of his "Prospect"[10]. He says that he wrote the article to direct the attention of the dairy farmers to the existence of cowpox. A few weeks later he showed Jenner's book at a meeting of the American Academy of Arts and Sciences. The president of the United States, John Adams, was at the meeting and was much interested[12]. Waterhouse conceived it his duty, considering his official position in the University, to give the matter a trial. After several unsuccessful attempts to obtain cowpox matter from England, Waterhouse succeeded in getting some from Dr. Haygarth of Bath—this lymph having come from Jenner's stock. With this matter he vaccinated seven members of his own family, and thereafter he invited Dr. Aspinwall, the physician to the smallpox hospital, to inoculate them with smallpox virus. The test was quite successful, though all were not inoculated. He then says that he had laboured to collect all the evidence on this subject, and to lay it "before the American public, in so plain and simple a manner, as to require no other preparation for its admission than common sense and an unprejudiced mind"[10]. Waterhouse had obviously been receiving requests for vaccine matter from professional men, and in an

Lyman Spalding
From J. A. Spalding

ppendix to the first part of his "Prospect", which dated from Cambridge, August 18, 1800, he writes : To those of the faculty who have applied to him y letter *to supply them with matter for inoculation* -He would just observe, that as he has taken much ains in this business, run no small risk of reputation, s well as of personal feelings, there are *few* he trusts, hat will wonder he is anxious to have the matter nder his own eye until the practice is more firmly stablished by the public opinion. Some unsuccessful ases at the beginning, deprived Scotland of the lessing of inoculation for the small-pox for more than 0 years. He hopes this idea will operate as an excuse t present, even in the minds of his *ci-devant* upils.

"Dr. Waterhouse informs those who have applied him out of Cambridge, to inoculate their families, hat he declined it only until the disorder had gone irly through his own family, and until some of them ad been inoculated by Dr. Aspinwall, and otherwise xposed to the small-pox. But having now confirmed is assertion, *that the kine-pox protects the constitution from the infection of the small-pox*, by a fair xperiment, he is ready to attend them whenever ey choose. Those who live in Boston, may rest ssured, that from the proximity of his residence to e capital, he shall make such arrangements as to be ble to attend them as punctually as if he resided ere."

In Part 2 of his "Prospect", published in 1802, aterhouse says that by September 1, 1800, he had accinated about fifty persons. The public attention as now fairly excited, and he was embarrassed by umerous applications for vaccine. But soon everyody believed that the operation of arm-to-arm accination was a simple matter and could be perrmed by anyone. Gone was Jenner's advice on the rrect stage of the vesicle for the withdrawal of lymph ; gone also were Waterhouse's own injunctions. Women and children were encouraged to inoculate each other, and by the autumn of 1800 there was a traffic in cowpox matter by non-professional persons. Waterhouse says : "I have known the shirt sleeve of a patient, stiff with the purulent discharge from a foul ulcer, made so by unskillful management, and full three weeks after vaccination, and in which there could have been none of the specific virus ; I have known this cut up into small strips, and sold about the country as genuine kine-pock matter, and coming directly from me. Several hundred people were inoculated with this caustic morbid poison, which produced great inflammation, sickness, fever, and in several cases *eruptions*, with a greater disturbance of the system than what occurs in the true disease. It is worthy of remark, that I could not influence these people to believe that they had *not* passed through the true disease, and that they were *not* secure from the small-pox."

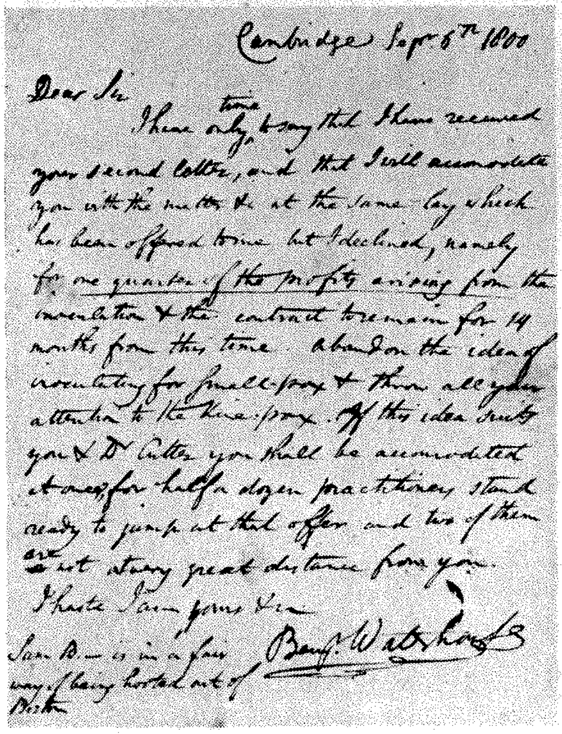
At Marblehead a vessel arrived from London having aboard a sailor supposed to have cowpox. Matter was taken from him and distributed widely, and many cases of smallpox resulted. However, in the winter of 1801, Waterhouse obtained new matter from England, and advice from Jenner. As a result, the practice of vaccination was successfully established in Massachusetts.

Waterhouse always regarded Jenner with the greatest admiration and respect. It is worthy of note that, in a letter which he wrote to Jenner on April 24, 1801[13], Waterhouse tells of the transmission of smallpox to cows. At one of the inoculation hospitals—where smallpox matter was used—several persons drove their cows to the neighbourhood, so that they could be milked for their families in the hospital. The milking was done by persons in all stages of the smallpox. The cows developed eruptions on their teats and udders, "so like the small-pox pustule, that every one in the hospital, as well as the physician who told me, declared the cows had the small-pox".

Dr. Lyman Spalding

During the early stages, when Waterhouse was receiving many requests for vaccine lymph, he had correspondence with Dr. Lyman Spalding. Most of this correspondence was published in a biography of Spalding by his grandson[14]. Some of it has also been re-published, notably by Leikind[15]. As the originals of two of these letters are now in the Wellcome Collection, and as this story is virtually unknown in Britain, they are re-printed here in facsimile. They illustrate an amusing incident, which was perhaps unavoidable in the social atmosphere of that time, but which is not at all representative of Waterhouse's character and of the great work which he did for vaccination and American medicine.

Lyman Spalding[16,17], the originator of the United States Pharmacopœia, was born in Cornish, New Hampshire, on June 5, 1775. As a boy he attracted the attention of Dr. Nathan Smith, who finally had him sent to the Harvard Medical School. He was a pupil of Waterhouse, and graduated in 1797. He assisted Smith in the foundation of the Dartmouth Medical School in 1797, and he gave the first course of chemical lectures when the school was opened. He then studied medicine and practised at Portsmouth, New Hampshire. There he printed yearly bills of mortality, and sent them to the leaders of the profession in America and in Europe. He was well known



Cambridge Sept 6th 1800

Dear Sir

I have only time to say that I have received your second letter, and that I will accomodate you with the matter &c at the same lay which has been offered to me but I declined, namely for one quarter of the profits arising from the inoculation & the contract to remain for 14 months from this time. Abandon the idea of inoculating for small-pox & throw all your attention to the kine-pox. If this idea suits you & Dr Cutter you shall be accomodated at once, for half a dozen practitioners stand ready to jump at that offer and two of them are not at very great distance from you.

I haste I am yours &c

Benjn Waterhouse

Sam B.— is in a fair way of being hooted out of Boston

(*a*) Letter from Waterhouse to Spalding
Original in the Wellcome Historical Medical Museum (39826·1)

as an anatomist and a surgeon, and he was the first in America to inject the lymphatics. In 1810 he was invited to lecture at the Fairfield Medical School in New York State, and in 1813 he became president of the institution. He now established himself in New York City. Even in 1815 he had the idea of a national pharmacopœia ; but it was not until 1820 that he was able to reconcile conflicting interests, and the first edition was published in that year. Spalding died as the result of an accident on October 21, 1821.

Letters in the Wellcome Collection

The two letters to which I referred are reproduced here in facsimile. The texts are as follows :

(*a*) Waterhouse to Lyman Spalding, at Portsmouth (W.H.M.M. (39826·1)) :

"Cambridge, Sept. 6th, 1800.

Dear Sir,

I have only time to say that I have received your second letter, and that I will accomodate you with the matter &c at the same lay which has been offered to me but I declined, namely for *one quarter of the profits arising from* the inoculation & the contract to remain for 14 months from this time. Abandon the idea of inoculating for small-pox & throw all your attention to the kine-pox. If this idea suits you & Dr Cutter you shall be accomodated at once, for half a dozen practitioners stand ready to jump at that offer and two of them are not at very great distance from you.

I haste I am Yours &c

Benjn. Waterhouse

Sam B.— is in a fair way of being hooted out of Boston."

(*b*) Spalding to Waterhouse (W.H.M.M. (39826·2))

"Portsmouth 10 Sept 1800

The terms are accepted, & I promise that you shall have one quarter part of the neat profit arising from my inoculation with the kine pox for the space of 14 months, provided it be not made public before that term expires—& then the contract to remain in full force only to the time of its becoming public however on your part it is expected, that the like priviledge will not be granted to others in my vicinity.

L. Spalding.

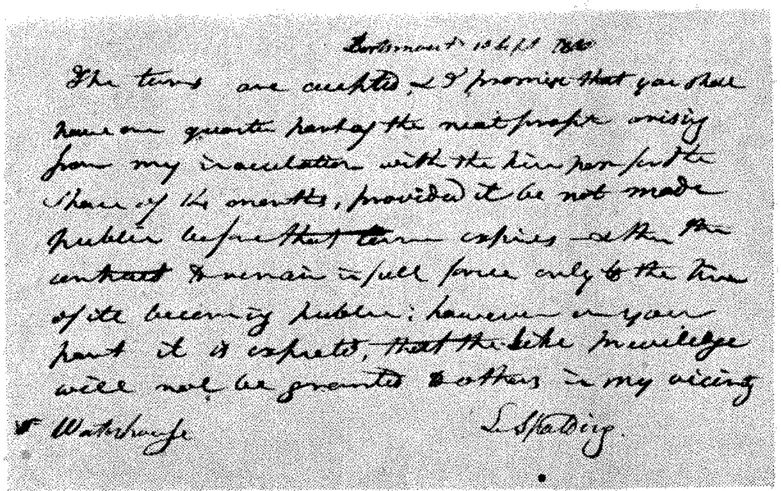
Dr. Waterhouse"

Additional Material of J. A. Spalding

James Alfred Spalding was the grandson of Lyman Spalding. He was born in 1842. In 1908 he was given Lyman Spalding's papers to look over, and this biography[14] was published in 1916. This book is very little known and there is probably only one copy in the libraries of London. It is not in the British Museum.

Since the biographer had all the papers, he was able to give much additional information on this interesting subject. The correspondence opened on August 25, 1800, when Spalding heard that Waterhouse had vaccinated his household successfully, and he asked for a supply of lymph. Waterhouse replied on September 6, 1800, advising Spalding not to vaccinate in a smallpox hospital. It is not clear whether Spalding had meanwhile written again ; but, though there is confusion of dates, this must be the case. Waterhouse then wrote the letter which is reproduced here as letter (*a*). J. A. Spalding says that Lyman's reply had not been preserved ; but that there was a copy of it. This must be letter (*b*). It is apparently written and signed by Lyman Spalding, and bears th name of Waterhouse on the revers —as if it had been given to som friend to deliver.

The Dr. Cutter mentioned in letter (*a*) may have been either th father or the son—both being well known physicians at Portsmouth "Sam B." was Sam Brown, who had been a friend of Lyman Spaldin



Portsmouth 10 Sept 1800

Dr Waterhouse

L Spalding

(*b*) Letter from Spalding to Waterhouse
Original in the Wellcome Historical Medical Museum (39826·2)

at Harvard. Lyman Spalding was the youngest physician in the town, and Waterhouse was evidently disinclined to give his cowpox matter to him alone, to the exclusion of an older physician.

Sam Brown had been following up the patients vaccinated by Waterhouse, to see whether the scabs could not be used to vaccinate his own patients. In his next letter—September 12—Waterhouse says that the time factor proposed is too vague, as Sam Brown may steal the method within a month. He therefore proposed that the term should be for twelve months. "You, however, will have *got the start of all the others*, so much that no one can rival you entirely; besides it will fix you in business. My fee is Five Dollars." Each man stuck to his guns—Spalding for monopoly, Waterhouse for Cutter and a higher figure. On September 18, Waterhouse informed Spalding that he had divided New Hampshire into three vaccination districts, with the exception of certain specified towns.

At this time the method was generally in use of transmitting the vaccine matter on pieces of linen thread, and it was for one of these threads that the bargaining was taking place. From a bond which existed when the book was written, it would appear that Waterhouse sometimes let one of these go for 150 dollars. On September 25, however, Waterhouse did send Spalding a thread; but he did so under protest that older men should have been included in partnership, and declared that he hoped that Lyman would take them in with him, so that vaccination could be extended everywhere as rapidly as possible. Spalding acted at once on receipt of the thread, and in one day vaccinated thirty persons. Shortly after this it was found that the virus could be passed from arm to arm, and linen threads and bonds immediately became valueless.

The two letters reproduced here in facsimile were presented to the Wellcome Historical Museum by Sir William Osler on January 31, 1919, eleven months before his death. In the note accompanying the two documents, Osler said that from them it would be seen that "they tried to make it a commercial affair; this I did not know". Item 6814 in the "Bibliotheca Osleriana"—the printed catalogue of Osler's library—is this biography by J. A. Spalding, and it seems strange that Osler had not at least glanced at it.

The manner in which these two letters came into Osler's hands is unknown. One can only assume that these two items were given to someone from the Spalding collection. If they had been given to Osler direct by the owner of that collection, Osler would have known a lot about the subject. Further, if the Spalding collection had been broken up, he would almost certainly have heard the fact. Would he not also have picked up many more letters, for was he not "William the Fowler, Guillaume l'Oiseleur", who kept all that was taken in his net ?[17]. It would be of interest to know what has happened to the Spalding letters as a whole.

On March 4, 1801, Jenner wrote his first letter to Waterhouse. It is a long letter full of sound advice, and is published by Waterhouse in full in the second part of his "Prospect". In 1802 Waterhouse was for a time forced to hire volunteers in Cambridge to keep up the strain of fresh virus. The correspondence with Jenner continued. This second part of the "Prospect" was criticized by the Massachusetts Medical Society as being obscure and not worth looking at. But he was much helped by British friends, and the book sold fairly well in the South. Meanwhile, vaccination was spreading to other parts of the United States, and this is too large a subject to deal with here.

A Third Letter in the Wellcome Collection

This is half of a four-page letter on foolscap. It has not, so far as I know, been published previously. The text is as follows:

(c) Waterhouse to an unknown correspondent (W.H.M.M. (95443)):

". . . I have just finished reading the different state papers relative to the armed neutrality. Partial as I am to Old England, I must confess that I think these northern nations have truth, and reason on their side. I do not see at present what arguments Great Britain can bring to bear against them, unless it be the *ultima ratio regum*, and that may not be a conclusive one, while this confederacy is so strong, aided as it is, by so potent a monarch as that of Prussia. France will doubtless try to bring us into this combination, and probably will expect to accomplish her views under *Jefferson*, which she would have despaired of under *Adams*. She will nevertheless fail in her expectations. The merchantile interest has great weight in these States, and our Executive cannot bend it to its wishes.

"Jefferson is a prudent man. He sets out with conciliating parties. He says 'we are all federalists, all republicans', and has delivered *sentiments* universally approved & admired. His speech is doubtless in London before this time. As a fine composition the man of taste will read it with pleasure. Jefferson is besides a man of mild & pleasing manners, naturally disposed to complaisancy, whereas Adams was a perfect *John Bull*, and accompanied his honesty with a roughness that in some cases narrowed his way to usefulness. You will find President Jefferson's speech in one of the papers in the box containing the cheese.

"I have just written to our Medical Society to ask their advice respecting the best method of diffusing the vaccine matter through our Land. I have also proposed to them a plan for a *Vaccine Institution* for inoculating the poor gratis. I wish I could obtain a copy of the rules, directions &c &c of the Vaccine Institution in London. Had I thought of it earlier, I would have requested a copy of it from Dr. Pearson.

"I am sorry, very sorry to hear that Jenner & Woodville even glance in their respective works at anything like personalities. We have honored & esteemed these celebrated men for their beneficent productions, and shall lament if in place of affording us more good & wholesome fruit, they should produce thorns. For more than a year I have held up these two eminent physicians to the *American public*, as men who could scarcely err. On that account I feel doubly mortified, that two, out of the three oracles which I have constantly appealed to, should clash in opinion. We feel interested in those we admire.

"I think I have already said that the matter which was on thread between two plates of glass, envelloped in a note to you signed '*Jno. Cn. Wachsel*', produced the disease to *perfection* in every patient I inoculated with it.

"I propose to write again in about a month by a Mr. Nancrede, one of our first booksellers. Till then adieu! and remember that I am your affectionate friend

B. Waterhouse"

April 14th, 1801

In this letter the direct comparison of Jefferson with Adams is interesting. Waterhouse had had contacts with both these presidents of the United States. When he was at Leyden, John Adams was sent by Congress to Holland to court an alliance, but he was forced to remain a year before he was publicly recognized as the American minister. During this time Adams, his two sons, his secretary, and Waterhouse formed one family[9]. Twenty years later he sent Jefferson a copy of his pamphlet on cow-pox—that is, the first part of his "Prospect"—and on December 25, 1800, the President sent him a very cordial letter of thanks, which Waterhouse published in his second part[11]. Six months later Waterhouse wrote a long letter to Jefferson, giving instructions how to perform vaccination, enclosing infected thread and books and drawings. In this letter he also suggested that the President should arrange for an experiment to be made by "some cautious discerning person, perhaps his own family physician. A series of experiments may be directly instituted by him." Three unsuccessful attempts were made to vaccinate the President's family with three separate batches of "virus". A fourth attempt was successful. The President was attentive to all applications made to him for cowpox matter, and he it was who was thus responsible for introducing vaccination into the District of Columbia, Pennsylvania, Maryland and Virginia.

The reference to Woodville recalls the fact that he was one of the first in London—after Cline—to practise vaccination. But he performed the operation in the Smallpox Hospital, and three days after vaccinating he inoculated the patients with smallpox matter. The result was that the "cowpox matter" from the pustule was really a combination of cowpox matter and smallpox matter. This material, distributed far and wide, caused many smallpox rashes. Jenner had considerable difficulty in saving the situation.

The great esteem in which Waterhouse held Jenner is seen in this letter, and is even more fully expressed in the second part of his "Prospect"[19].

Back to Jenner

If much of this article has been devoted to persons other than Jenner he would not have minded—even on his birthday. In the mass of correspondence which has been preserved, dating from the time of publication of the "Inquiry", we get a very good picture of the man. During the early stages of the movement to promote vaccination he was the oracle to whom everyone turned for guidance, and loaded with honours as he was, he never lost his head. Even his erroneous views—and that there must have been erroneous views at that period when immunology was still unborn is obvious—were often blessings which kept some semblance of correctness when some men tended to stray into dangerous by-ways.

Jenner became almost at once a national hero, and his name was nearly as well known abroad as it was in his own country. His vast correspondence led him to term himself "the vaccine clerk of the whole world". His private practice certainly suffered, and in 1802 Parliament made him a grant of £10,000. In 1806 he was voted a further £20,000. To the end he worked unceasingly for the cause of vaccination. On January 26, 1823, he passed peacefully to his rest.

Jenner never cared very much for the high honours which he received; but he did care a great deal for the practice which he had discovered and helped to foster. That is why he would have perhaps preferred an article on the movement to a eulogy of the man.

INDUSTRIAL RESEARCH AND MANAGEMENT

A WEEK-END conference of industrial research directors and managers was held at Ashorne Hill, near Leamington Spa, during March 11–14. It was organised by the Industrial Research Committee of the Federation of British Industries, under the chairmanship of Sir Wallace Akers. The proceedings of the conference were divided into five sessions, at each of which two papers were read. Except for the first session, at which spoken contributions to the papers were made from the body of the hall, the arrangements for discussion were unusual. Immediately after the reading of the papers, the company was divided into six groups which repaired to separate rooms, where each group appointed a chairman to guide about an hour's discussion. Afterwards, the conference re-assembled and the six chairmen reported. Sometimes the groups were given specific questions to try to answer, at others their discussion was unrestricted. In either case, the method appeared to be remarkably successful in promoting full discussion of the papers in the short time available.

At the first session papers were read on the relationship between the research department and the management and other departments of an industrial organisation. Mr. F. H. Saniter described the origin and development of the United Steel Companies' Research and Development Department. It is recognized, Mr. Saniter said, that the amount of new knowledge created by an industrial research establishment is small in relation to the new knowledge continually becoming available from all sources. The Research and Development Department is therefore regarded as having three main functions: collection and dissemination of information, creation of new knowledge by research, and application of knowledge, from whatever source, to practice. The effective functioning of such a department depends on its proper integration into the general structure of the company. At the United Steel Companies this is achieved by a series of committees ranging from a top-level committee, under the chairmanship of the managing director, downwards. These committees are considered primarily as a means of bringing people together periodically to discuss the technical needs of the firm and the ways in which they can be met by the Research and Development Department.

Dr. W. D. Scott (Monsanto Chemicals, Ltd.) gave the second paper in this session, and widened the scope of the discussion to embrace the influence of the research mind throughout the entire industrial organisation. He pointed out that there are three prime executive functions to be performed: to produce, to sell and to plan. The planning function is the intimate concern of the research department, the relationship of which to the management can be established through a number of different types of internal organisation which were illustrated by charts. Throughout, the emphasis was on a proper appraisal of the financial implications of the activities of the research department, particularly in the selection and continuation of research projects.

"Finance, Costing, Laboratory Administration and Scientific Staff, Research Programmes and their Formulation" was the comprehensive subject-heading of the second session, and both the papers and discussion which followed were of necessity selective. Mr. A. W. Montgomery (Standard Telephones and Cables, Ltd.) dealt mainly with human relationships in the research laboratory. Every establishment needs rules, however few, and since research scientists are usually knowledgeable and intelligent people, the rules of a research organisation must be reasonable and arguable. Provision must be made for staff training after engagement, and the need for adding wisdom to knowledge was emphasized. The difficult question of special treatment given to any particular member of a laboratory was touched upon, also the problem of how to treat fairly and employ correctly the older scientific worker of considerable experience who, although he has kept his knowledge up to date, has to some extent, of necessity, lost his original fire and enthusiasm. In one laboratory in the United States, such people are transferred to a group of consultants who are free of access to any individual in the company. In other places their experience is often used successfully in other parts of the company.

Another problem of great difficulty is to decide when a piece of work is complete. It is necessary to stop the work at suitable stages and consider how much can be applied, since it is through the application of research results that the upkeep of the laboratories is ultimately paid for.

Dr. I. J. Faulkner (I.C.I.), dealing with the organisation of research in the chemical industry, emphasized the necessity of not overburdening the research staff with administrative duties. It is also desirable that no individual should have to look after too many others; between four and six was considered to be the maximum. Such small teams can be easily handled, and all have a reasonably rapid approach to their chief.

A special type of organisation is required where research is carried out on a factory-scale. At the I.C.I. works at Billingham, semi-technical and pilot plant involve several hundred pay-roll employees, as well as design, construction and maintenance engineers. This is all brought under the 'research works manager', who takes off the research staff the heavy task of administering this kind of large-scale research activity. He is directly responsible, along with four other assistant research managers concerned with smaller scale research, to the research director.

The distinction between the research budget, the programme expenditure and the costing of research was also discussed by Dr. Faulkner. There are difficult decisions involved in the detailed costing of research, the allocation of costs and the definition of 'overheads', as well as in answering the all-important question, "How much should be spent on research?"

The third session, on the "Application of Research to Production", was opened with a paper from Dr. J. Park (British Oxygen Co.). Industry, and in particular the production man, the salesman and the accountant, live by what is being made now, and they inevitably acquire a vested interest in the present. The research man is concerned with what is coming next and is less interested in existing processes. The research department must win confidence at an early stage and prove that it is more than a 'frill' paid for by the profits of the other departments. It must remember that no new product is industrially significant unless somebody can find a use for it. A modest contribution to the company's present business may win more respect than a successful piece of fundamental work. Finally, the results of research must be effectively 'sold', the proper sales instrument being the concise and clearly worded research report.

Mr. L. J. Davies (B.T.H., Ltd.) classified industrial researches into five groups: (1) ancillary researches (instrumentation, measurement, etc.); (2) materials research; (3) process research; (4) design research; and (5) device research or invention. The difficulties, both technical and personal, which have to be overcome in the course of introducing new methods were illustrated by two examples taken from the electrical industry.

In the fourth session, on "Information and Intelligence, Publications and Publicity", Mr. O. W. Humphreys (General Electric Co., Ltd.) touched upon a topic which was much in evidence in the informal discussions throughout the conference, namely, the form and style of scientific reports. He said that the scientific paper enjoyable for style as well as subject-matter is all too rare; and he thinks that lectures on the English language should be included in all science and engineering courses. Any necessary reduction in the standard of the first degree would be worth it in return for some attention to the humanities.

Dr. C. G. Williams (Shell Petroleum Co.) spoke on the problem of keeping in adequate touch with the ever-rising output of technical literature. As much as can be assimilated in one to two hours a day of general technical reading was thought to be sufficient without too much interference with practical work or risk of mental indigestion. The habit of abstracting is valuable, but classification presents problems; there does not seem to be general acceptance of the Universal Decimal Classification.

The importance of presenting the results of research was emphasized by means of a formula:

$$\text{value of a research} = \begin{array}{c}\text{worth-whileness}\\ \text{of objective}\end{array} \times \begin{array}{c}\text{efficiency of}\\ \text{presentation}\end{array} \times \begin{array}{c}\text{effectiveness of}\\ \text{reporting.}\end{array}$$

If any one of these three factors is zero, the result is zero.

Dr. L. B. Pfeil, in the first paper of the fifth session, described the relationships between the Mond Nickel

Co.'s Research and Development Department and the research associations, universities and Government departments. He made a strong plea for the expansion of Government research activities by enlargement of such establishments as the National Physical Laboratory. There is a great lack of fundamental data now badly needed by industry. Germany was, before the War, a substantial contributor to the pool of fundamental knowledge, but this source has dried up. The work of the N.P.L. and similar establishments is valuable, but much more is needed.

The universities should not generally be used as consultants by industry, but should concentrate rather on the task of providing men of sound character and personality who can think honestly and convey their thoughts with facility to others. Government grants to students and research workers are more helpful in this direction.

Mr. R. M. Winter (I.C.I. Ltd.) urged that fundamental research at the universities should not be swamped by purely tutorial duties. The training of first-class research workers is of more importance that a large output of technicians trained mainly in manipulative skills and laboratory methods. The present urgent requirements for scientific man-power should not be allowed to lower the standards of training of fundamental scientific workers. The Government's spending of £69 millions in 1947–48 on research and development, of which recurrent grants to universities and similar institutions accounts for only £3½ millions, invites comment, Mr. Winter said.

The discussions which followed each of the five sessions were so varied and often lively as to make them difficult to summarize. There appeared, however, to be a general concern over both the quantity and quality of new recruits to the industrial research laboratories. The problem of quantity is largely a result of heavy demand coupled with interruptions to the normal flow of graduates from the universities caused by the War and by the subsequent arrangements for military service. On the side of quality, there was a strong feeling that scientific education should be on broader and less specialized lines, particularly up to the first degree.

As regards the conference as a whole, there was a general impression that it had provided an excellent opportunity for the airing and discussion, between research executives in different industries, of many common problems and interests.

W. C. F. Hessenberg

OBITUARY

Dr. G. Shearer

George Shearer died on March 13 in Addenbrookes Hospital, Cambridge, on the eve of his fifty-ninth birthday.

Shearer entered the University of Edinburgh from George Watson's College in 1907, having taken high places in both the John Welsh Classical and Mathematical Bursaries lists: for his first session he read Latin and Greek, and graduated as M.A. and B.Sc. in 1912 in mathematics and natural philosophy. He remained at Edinburgh as an assistant in natural philosophy until the outbreak of the First World War, and during this period published his first papers, on atmospheric electric potential, and Fourier and periodogram analysis, in collaboration with Dr. G. A. Carse; during this period, too, he began, under Barkla, his X-ray work, which was to be the main subject of his scientific work for the next quarter of a century. As an instructor lieutenant in the Royal Navy during 1914–19 he served afloat on navigational and gunnery duties.

On his release from war service, Shearer resumed his X-ray researches, going to Emmanuel College, Cambridge, as an 1851 Exhibition research student, and working at the Cavendish Laboratory under Rutherford. In 1922 he moved to London, as chief research assistant to Sir William Bragg, first at University College and, from 1923, at the Davy Faraday Laboratory, Royal Institution. During this period he was particularly interested in the newly discovered technique of X-ray photography of powders, and developed the application of this method to the study of the geometry and the symmetry, both of the crystalline arrangement and of the molecules themselves; one of his outstanding achievements was the X-ray chemical analysis and identification of long-chain ketones.

In 1927 Shearer was appointed to the National Physical Laboratory as a senior assistant to take charge of the work for the Committee on the Application of X-ray Methods to Industrial Problems. The group under his charge developed and used both X-ray and electron diffraction techniques, and devised various special items of equipment, such as a rotating anode tube. The problems tackled included the structure of many industrial materials (special steels, paint materials, carbon blacks, insulating materials, etc.) and the basic properties of metals. On the outbreak of the Second World War, he was transferred to the Metrology Division for work on gauges for war production. In 1941 he was seconded, and in 1948 was posted, to the Research Department (now the Armament Research Establishment) of the Ministry of Supply, in which he served until his death; in this last appointment he returned to Cambridge in charge of an out-station, and in 1947 his promotion to senior principal scientific officer enlarged his responsibilities to include the charge of other out-stations. The group of which he was the inspiration was studying the penetration of armour by projectiles, and their work contributed largely to the effectiveness of the British anti-tank artillery and aircraft cannon. Shearer's encouragement and guidance greatly facilitated the application to ballistic problems of such techniques as 'Arditron' flash photography and Kerr cell shutters.

Shearer was granted the degree of Ph.D. at Cambridge in 1921 and D.Sc. at Edinburgh in 1923 for his X-ray work. He was a fellow of the Institute of Physics and of the Physical Society, and a member and past president of the British Institute of Radiology. He also served as a member and chairman of the Committee of Visitors, and as a member of the Committee of Managers, of the Royal Institution.

On his return to Cambridge in 1941, Shearer again had rooms in his old College, Emmanuel. This was a great joy to him, although the arduous nature of his duties left him little leisure for his favourite recreations, bridge and golf, at both of which he was no mean performer. During these years he made a real contribution to the social life of the High Table and the Parlour of the College, and his wide interests and broad sympathies made him a gracious host to many official visitors. An able physicist, a wise administrator, and a modest man, he will be missed by many friends.

NEWS and VIEWS

Biochemistry at Cambridge : Prof. A. C. Chibnall, F.R.S.

PROF. A. C. CHIBNALL, whose impending retirement from the Sir William Dunn chair of biochemistry has recently been announced, has held his present position since 1943. During his period of tenure, the Department of Biochemistry at Cambridge has fully maintained its former distinguished record. Under his guidance there have not only been developments in the major themes of research on the dynamic aspects of biochemistry for which the Department became famous under the late Sir Frederick Gowland Hopkins ; in addition, much more attention has been paid than in the past to the biochemistry of proteins, a subject in which Prof. Chibnall himself is especially interested. As might be expected also, plant biochemistry at Cambridge has received much encouragement at his hands. A notable development which has occurred under Prof. Chibnall is the expansion of work on microbiological chemistry ; this has led to the recognition of microbiological chemistry in the Natural Sciences Tripos, and to the establishment of a major division of the Department, headed first by the late Dr. Marjory Stephenson and now by Dr. E. F. Gale, with responsibility for research and the training of students in this branch of biochemistry. Although Prof. Chibnall's tenure of the chair at Cambridge has been short, he has thus very definitely left his mark on the Department. The regret of his scientific colleagues at his early retirement will be tempered by their knowledge of his intention to remain in Cambridge and to devote to scientific research the time liberated by relief from duties of administration and teaching. Doubtless also his wide knowledge and experience will continue to be available to such bodies as the Agricultural Research Council, to which he has given so much help in the past.

Prof. F. G. Young, F.R.S.

PROF. CHIBNALL will be succeeded in October next by Prof. F. G. Young, who will thus be leaving University College, London, after having held the chair of biochemistry there since 1945. During the War the Biochemical Department of University College was evacuated from London, and one of his main tasks on appointment in 1945 was to superintend its return and to adapt it to post-war needs. This he has done with conspicuous success. Not only have the laboratories been more or less completely re-equipped, but also the teaching provided has been brought up to date by the introduction of a new course leading to the degree of M.Sc. in biochemistry. Prof. Young's research interests are in the sphere of carbohydrate metabolism, and brief mention of his activities to 1945 was made in a previous note (*Nature*, 156, 471 ; 1945). His outstanding achievement has been the production of permanent experimental diabetes in animals by injection of anterior pituitary extracts, and he has subjected the whole question of pituitary control of the insulin-secreting function of the pancreas to close and skilful experimental analysis. The value of his work was recognized recently by his election to the fellowship of the Royal Society. Under Prof. Young's vigorous leadership, the Biochemical Department at University College has become once again a flourishing centre for teaching and research, and his pending departure will be viewed by his colleagues there with great regret. He goes to Cambridge with an established reputation, and he carries with him the good wishes of his numerous friends at home and abroad.

Specialization at Universities

THE numbers of university undergraduates, in the technical faculties especially, are to-day greater than ever before, and yet apprehension as to the true worth of university training was never so widespread as at the present time ; for modern scholarship has made such strides, particularly in the field of science, that no one subject can be adequately studied without undue specialization and consequent neglect of other points of view. This danger of specialization was the theme of Mr. Oliver Stanley's recent address, on being installed as chancellor of the University of Liverpool, when he said that too many men and women to-day leave a university complete masters of a subject but still incomplete individuals, unable to act as evangelists of that broader culture, that more general philosophy which should be the university's gift to the people. These words were echoed by Mr. Winston Churchill when, on the same occasion, he received the honorary degree of doctor of laws. Indeed, Mr. Churchill went further and, to a certain extent, accused science of being the usurper of culture. Few men of science would seriously dispute that ". . . We need a lot of engineers but we do not need a world of modern engineers. . . . Science must be the servant and never the master of mankind" ; but Mr. Churchill's further statement, "I would venture to say that no amount of technical knowledge can replace the value of the humanities or the study of history", is one that is open to challenge. The study of science need not preclude a deep appreciation of the humanities ; rather it is the high degree of specialization within the syllabus which is the excuse for not teaching a general appreciation of scientific principles. Many physics graduates have very little knowledge of the processes of life, just as, say, the majority of botanists are probably unaware of even the elementary facts of the quantum theory or relativity ; and both know very little of either the history or philosophy of science. It is on this last point that, no doubt, science is lacking as a medium for educating (in the widest sense of the word) the student. If the teaching of science itself were less specialized and more cultural, then perhaps a scientific course would be more readily recognized as being as good an education as, say, a classical one, for training the undergraduate to become a leader of thought and action.

New Coalfield in Britain

IT has been announced by the Lord President of the Council that a new coalfield has been discovered in south Staffordshire during the course of deep boring by the Geological Survey of Great Britain. At a minimum estimate this coalfield contains 400 million tons of workable coal, and the amount may possibly be several times as great as this estimate. The seams lie at a depth of about 3,000 ft. ; thirty feet of coal has so far been discovered, including seams of 8, 6 and 5 ft. Boring is still going on, and it is likely that further seams will be found. The boring is at Whittington Heath near Lichfield. The new coalfield is situated between the Cannock Chase coalfield and the Warwickshire coalfield, in both of which the productive coal measures crop out at surface. Additional borings will be necessary to prove the full resources and detailed structure of the new field. Funds to undertake a programme of deep boring were granted to the Geological Survey in 1947 for the purpose of investigating the deep-seated geological structure of Great Britain. It is unlikely that all the bores will give direct economic results of such importance as the Lichfield bore; but the information gained from the bores will enable geologists to interpret the structure of the rocks at great depths beneath considerable areas of the country. Knowledge of this kind is of great general importance in the search for underground mineral and water resources. Mr. T. Eastwood, assistant director of the Geological Survey in charge of mineral deposits of England and Wales, is responsible for the work. Boring has been carried out by the Craelius Company under contract.

Universities of the British Commonwealth: Congress in Canada

A MEETING of representative vice-chancellors and principals of the various countries of the British Commonwealth is to be held in Canada next month. At the Congress of Universities of the Commonwealth held at Oxford in July 1948, it was decided that there should be smaller meetings of executive heads of universities annually in some part of the Commonwealth in order to discuss matters of common policy, including the implementation of the decisions of the Congress on inter-university relationships (interchange of staff, students, etc.). This, the first of such conferences, will take the form of a meeting of the Executive Council of the Association of Universities of the British Commonwealth, and will be held at Halifax, Nova Scotia, during June 10–11, followed by the annual meeting of the National Conference of Canadian Universities during June 12–15, at which the overseas representatives will be guests. The conference will conclude with a meeting in Montreal on June 17. The president of McGill University, Dr. F. Cyril James, will preside, and the local arrangements are in the hands of Mr. T. H. Matthews, registrar of McGill University and secretary–treasurer of the National Conference of Canadian Universities.

The following is a list of delegates who will be attending the Conference. *Great Britain and Ireland:* Sir David Lindsay Keir (vice-chancellor, Queen's University, Belfast), Very Rev. Dr. J. Lowe (vice-chancellor, University of Oxford) and Prof. Lillian Penson (vice-chancellor, University of London). *Canada* (representatives on Executive Council): Dr. F. Cyril James (principal, McGill University, Montreal), Monseigneur F. Vandry (rector, Laval University, Quebec) and Dr. R. C. Wallace (principal, Queen's University, Kingston, Ontario). *Australia:* Prof. D. B. Copland (vice-chancellor, Australian National University) and Prof. W. Prest (dean of the Faculty of Commerce, University of Melbourne). *South Africa:* Dr. E. G. Malherbe (principal, University of Natal) and Dr. H. R. Raikes (vice-chancellor, University of the Witwatersrand). *New Zealand:* Dr. R. S. Aitken (vice-chancellor, University of Otago). *India and Ceylon:* Dr. P. N. Banerjee (vice-chancellor, University of Calcutta) and Sir A. Lakshmanaswami Mudaliar (vice-chancellor, University of Madras). *Pakistan:* Dr. S. M. Hossain (vice-chancellor, University of Dacca). *Other parts of the Commonwealth:* Colonel Lindsay Ride (vice-chancellor, University of Hong Kong). *Officers o the Association:* Sir William Hamilton Fyfe (honorary treasurer, formerly vice-chancellor, Queen's University, Kingston, Ontario, and University o Aberdeen), Mr. J. F. Foster (secretary of the Association and of the Committee of Vice-Chancellors and Principals of Great Britain and Ireland, formerly registrar of the University of Melbourne, Australia and Miss Margaret Palstra.

Petroleum Oils and the Fruit-grower

A LECTURE given by Dr. T. Swarbrick to the Roya Society of Arts, on January 26, described, *inter alia* some interesting features of the use of petroleum oils for controlling the pests of fruit trees. One difficulty about their use was an occasional phytotoxic effect. The chemists of the Royal Dutch-Shel Group have now traced the cause of this damage and found methods for its removal. Earlier work by Chapman and Pearce indicated the necessary conditions of boiling point and viscosity which conferred insecticidal action. Petroleum can also be used as a total or selective weed-killer, and new methods of application are designed to reduce the amount of water required in spraying. Atomized oil sprays may need no more than 2¼ gallons of spray fluid per acre for crops of small fruit.

A Virus-inhibiting Protein

A GLYCOPROTEIN which can inhibit the activity of tobacco mosaic, tomato bushy stunt and other plant viruses has been isolated by B. Kassanis and A. Kleczkowski (*J. Gen. Microbiol.*, 2, No. 2; May 1948). It was obtained from the sap of *Phytolacca esculenta* by differential precipitation with ethanol followed by adsorption on 'Celite' and elution with 10 per cent sodium chloride. The protein is unaffected by pepsin and trypsin unless it is denatured, and it is not effective against bacteriophage.

Royal Institute of Chemistry

AT the annual general meeting of the Royal Institute of Chemistry held on April 28, it was announced that H.M. the King had been graciously pleased to grant to the Institute on April 14 a new royal charter in substitution for the original charter of 1885 and the supplemental charter of 1944. In the new charter it is made clear that the Institute is concerned with the whole profession of chemistry and not merely with that of "analytical and consulting chemistry", as stated in the original charter. The powers of the Institute have been modified in certain respects so as to facilitate the progressive development of its activities and services in the interests of the profession and of the public. The title of the Institute has been changed from "The Royal Institute of Chemistry of Great Britain and Ireland" to "The Royal Institute of Chemistry". It has been resolved to amend the by-laws so as to provide that citizens of Eire, as well as British subjects, shall be eligible for admission as members or for registration as students of the Institute. Resolutions were passed at the meeting authorizing the Council to establish, as a benevolent fund, a Residential Clubs Fund.

The following officers for 1949 were elected: *President*, Prof. J. W. Cook; *Vice-Presidents*, Prof. F. Challenger, Mr. H. Krall, Prof. R. P. Linstead, Mr. G. Roche Lynch, Mr. J. A. Oriel, Mr. E. T. Osborne; *Honorary Treasurer*, Dr. D. W. Kent-Jones.

Physical Society: Summer Meeting at Cambridge

The summer meeting of the Physical Society will be held this year in Cambridge during July 14–16. The main subject will be "The Ionosphere and the Propagation of Radio Waves". Among the speakers will be Prof. S. Chapman (Queen's College, Oxford), Mr. J. A. Ratcliffe (Cavendish Laboratory, Cambridge), Dr. A. C. B. Lovell (University of Manchester), Mr. G. Millington and Mr. S. B. Smith (Marconi Wireless Telegraph Co.), and representatives from the Radio Research Board and the British Broadcasting Corporation; visitors from France, Norway and Sweden are also expected. Attendance at the Conference is free to all members of the Physical Society; a fee of 10*s*. a day will be charged to non-members. Further details may be obtained from the offices of the Physical Society at 1 Lowther Gardens, Prince Consort Road, London, S.W.7. Non-members of the Society should apply by May 31.

Geological Society of London: Officers for 1949

At the annual general meeting on April 27 of the Geological Society of London, the following officers and members of the Council were elected for the coming year: *President*, Prof. C. E. Tilley; *Vice-Presidents*, Prof. J. A. Douglas, Prof. L. Hawkes, Dr. G. M. Lees and Prof. H. H. Read; *Secretaries*, Dr. D. Williams and Prof. S. E. Hollingworth; *Foreign Secretary*, Prof. O. T. Jones; *Treasurer*, Mr. P. Evans. *Other members of Council*: Dr. A. J. Bull, Mr. A. J. Butler, Dr. F. Dixey, Dr. K. C. Dunham, Dr. W. L. F. Nuttall, Dr. K. P. Oakley, Dr. J. Phemister, Prof. W. J. Pugh, Prof. F. W. Shotton, Dr. W. Campbell Smith, Dr. C. J. Stubblefield, Prof. D. M. S. Watson, Dr. E. I. White and Prof. Alan Wood.

University of Sheffield

The Council of the University of Sheffield has made the following appointments: B. R. Dudley, at present research assistant to the Professor of Engineering, to be lecturer in the Department of Mechanical Engineering; and Dr. Hsun Lee, at present independent research worker for the British Iron and Steel Research Association, to be research fellow in the Department of Metallurgy.

The following resignations were announced: Dr. J. A. Pope, senior lecturer in mechanical engineering, on his appointment to the chair of engineering in the University of Nottingham; Dr. J. H. Bowie, lecturer in bacteriology, on his appointment to the post of bacteriologist at the Royal Infirmary, Edinburgh; Dr. A. E. Bender, assistant lecturer in biochemistry, on his appointment as leader of a nutrition research team at the Crookes Laboratories.

The Night Sky in June

Full moon occurs on June 10d. 21h. 45m., U.T., and new moon on June 26d. 10h. 02m. The following conjunctions with the moon take place: June 3d. 04h., Saturn 3° S.; June 13d. 22h., Jupiter 5° N.; June 24d. 15h., Mars 4° S.; June 24d. 18h., Mercury 8° S.; June 27d. 21h., Venus 4° S.; June 30d. 13h., Saturn 2° S. Mercury is in inferior conjunction on June 3 and is stationary on June 15. The planet reaches greatest western elongation on June 28, and at the end of the month rises an hour before the sun. Venus is an evening star, setting about an hour after the sun during June, and can be seen for a short time in the western sky. Mars is a morning star, rising at 3h. 10m., 2h. 40m., and 2h. 12m., at the beginning, middle and end of the month, respectively, and is visible for a short time in the eastern sky. Jupiter is visible in the early morning hours, rising at 23h. 30m., 22h. 33m., and 21h. 30m. on June 1, 15 and 30, respectively. Saturn is visible during the earlier portion of the night, setting at 0h. 40m., 23h. 45m. and 22h. 50m. at the beginning, middle and end of the month, respectively. No occultations of stars occur during June. Summer solstice commences on June 21d. 18h.

Announcements

The Stephen Paget Memorial Lecture of the Research Defence Society will be delivered by Prof. C. Lovatt Evans, on the occasion of the annual general meeting of the Society on June 9; he will speak on "Physiological Research and the Vivisection Act".

Commdr. R. G. A. Jackson, of the Treasury, will examine with, and report to, the secretary of the Department of Scientific and Industrial Research, Sir Ben Lockspeiser, the administrative arrangements by which the Government is promoting the application of scientific knowledge to problems of productivity and economic development. Commdr. Jackson was director-general of the Middle East Supply Centre during the War, and later became an assistant secretary-general of the United Nations.

Mr. E. C. Cherry has been appointed to the Henry Mark Pease readership in telecommunications tenable at the Imperial College of Science and Technology, London, as from October 1.

The seventh International Botanical Congress will be held in Stockholm during July 12–20, 1950. Excursions in connexion with the Congress will start on June 27, and others to follow it will end on August 9. A preliminary programme and excursions can be obtained from the Secretary-General, Dr. Ewert Åberg, Uppsala 7.

The fourth Annual Electronics Exhibition of the North-Western Branch of the Institution of Electronics will be held at the College of Technology, Manchester, during July 19, 2.30 p.m.–9 p.m., and July 20–21, 10 a.m.–9 p.m. There will also be an exhibition of scientific films arranged by the Manchester Scientific Film Society. Admission to the Exhibition will be by ticket only, obtainable from Dr. J. A. Darbyshire, 'Melandra', 1 Kershaw Road, Failsworth, Manchester.

The French Physical Society is holding an Exhibition of scientific instruments and apparatus in the Salons de l'Université, Sorbonne, at 47 Rue des Écoles, Paris 5, during June 4–9. Further information with regard to the Exhibition may be obtained from M. Marandon, 61 Avenue de l'Observatoire, Paris 14. The Society is also holding a meeting on June 4 at which the Holweck Prize will be presented to Prof. L. F. Bates, of the University of Nottingham, who will give a lecture on "Thermal Effects due to Magnetization Processes in Weak Fields".

A summer school in the theory and application of the electron microscope will be held in the Cavendish Laboratory, Cambridge, during August 16–17. The course is intended for those who will be using electron microscopes in the near future, and the techniques of preparing specimens and of operating various microscopes will be practised. Further information can be obtained from Mr. G. F. Hickson, Secretary of the Board of Extra-Mural Studies, Stuart House, Cambridge.

Further Studies in Synthetic Polypeptides

OUR investigations of synthetic polypeptides, which have been proceeding concurrently with, although independently of, those described by Astbury and Dalgliesh[1], were also inspired by the announcement of the discovery of a benzene-soluble co-polymer prepared from anhydro-N-carboxy-DL-β-phenylalanine and L-leucine by Woodward and Schramm[2] using the Leuchs polymerization[3].

We would confirm the results of Astbury and Dalgliesh[1] that the majority of the synthetic polypeptides so far prepared give X-ray powder photographs resembling those given by β-proteins. We found, however, that the copolymers (1 : 1 mol.) of DL-β-phenylalanine and L-leucine, as prepared originally by Woodward and Schramm[2], and of DL-β-phenylalanine and α-amino-*iso*butyric acid, give X-ray powder photographs the two principal diffraction rings of which correspond to inter-planar spacings of 5·2 and 11·7 A. Films cast from solutions of these co-polymers in benzene, when examined with the X-ray beam parallel to the film surface, give an oriented diffraction pattern (Fig. 1) which is strikingly similar to those given by α-proteins. Some of these preparations of film are extensible, but stretching, even up to 100 per cent, does not appear to affect the X-ray photograph.

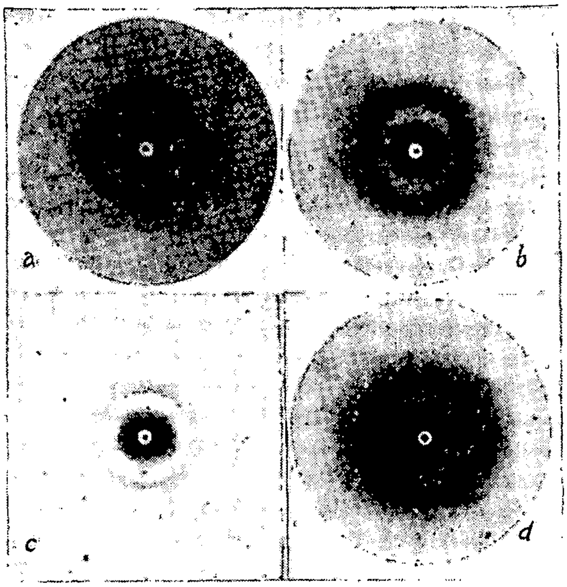

Fig. 1. X-Ray diffraction photographs of synthetic polypeptides: (*a*) film, stretched 50 per cent, with X-ray beam perpendicular; (*b*) film, stretched 50 per cent, with X-ray beam parallel to surface; (*c*) fibres, taut; (*d*) natural α-keratin, human hair, for comparison with (*c*)

In addition, we have now spun fibres of the DL-β-phenylalanine-L-leucine co-polymer. The X-ray photograph of these shows one marked difference from the photograph of the films. While the strongest meridional spacing remains at 5·2 A., the 11·7 A. reflexion becomes oriented on the equator in place of the 10·4 A. reflexion, which disappears altogether from the equator (see Fig. 2).

The similarity of the photograph of the synthetic fibres to that of natural keratin leads to some interesting suggestions regarding their structure. In the first place, we cannot be absolutely certain of the identity of the two photographs; but the spacings are so nearly the same and the general character of the photographs are so similar that we feel them to be produced by essentially the same type of molecular configuration. Up to the present, we have not been able to extend these synthetic fibres into the β-configuration, so complete analogy with natural keratin has not yet been established. The repeat period of the synthetic fibres is 10·4 A., whereas in silk with a fully extended peptide chain it is ~ 7 A., which is in agreement with the length calculated from known bond-lengths and -angles. This fact leads us to suggest that in protein fibres of the α-keratin class, both natural and synthetic, the polypeptide chains do not lie parallel to the length of the fibre, but transverse to it. If this were so, the structure would be held together along the fibre by hydrogen bond systems and by the interlocking of the side-chains (Fig. 3). Experiments are in progress to test the truth of these hypotheses.

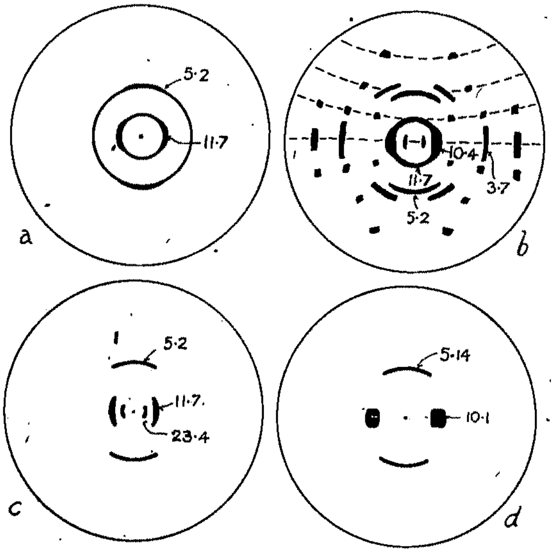

Fig. 2. Inter-planar spacings measured from corresponding photographs in Fig. 1

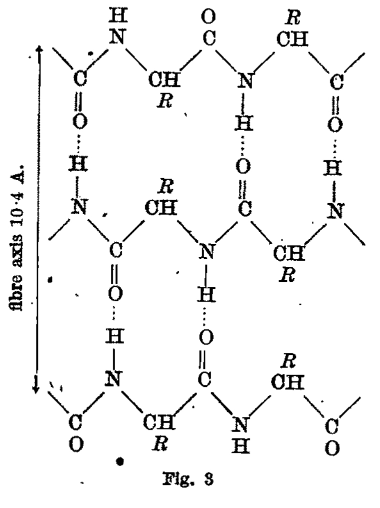

Fig. 3

The molecular weights of the films have been estimated by end-group methods; the nitrogen liberated in a Van Slyke amino-nitrogen apparatus, and the absorption of free carboxyl groups by methylene blue, both point to a figure in the neighbourhood of 15,000, very much lower than the "several million" quoted by Woodward and Schramm[2].

Organisms Producing Antibiotics in Tropical Soils

EXCEPT for some experiments by Meredith[1] with Jamaican soils, little information is available on the presence in tropical habitats of antibiotic-producing micro-organisms. Using a technique similar to that of Stokes and Woodward[2], we are finding increasing evidence that tropical soils harbour such organisms, sometimes types which have not yet been identified.

Actinomycetes, as was to be expected, are widely represented, but in our opinion are of much less interest than certain spore-forming and non-spore-forming aerobic bacteria which occur there. These produce a surprisingly selective inhibition of the growth of other organisms.

A short rod, for example, discovered by one of us (I. T.) in Trinidad air, and presumably carried there with soil particles, produces a water-soluble thermostable and apparently non-toxic antibiotic which arrests the growth of all the fungi and yeast tested —so far more than forty species. Its action is often a positive one in concentrations of less than one part in a million. Against Gram-positive and Gram-negative bacteria this antibiotic is inactive.

Another organism which has been isolated is active against fungi, bacteria (*Bact. coli commune*) and aerobic bacilli (*Bact. mycoides*), while others are effective against fungi and bacteria.

In one of the investigations now proceeding the presence of peptone in the culture medium is essential for the production of an antibiotic. In another series glucose and peptone are required. It has not yet been ascertained whether peptone can be replaced by amino-acids, and, if so, by which.

It is proposed to extend the study now in progress to cover tropical habitats other than soils, and to alter the technique employed so that organisms may be collected—if they should exist—which may require materials other than peptone and glucose for antibiotic production.

In his review of bacteria in soil, Conn[3] refers to the isolation of antibiotic organisms from soils. He admits the interest of such work, which he classifies as both important and practical, though not agriculturally significant. We suggest that the existence of organisms producing antibiotics may play a part in maintaining a balanced microflora in soil. In this we are in full agreement with the views of Brian[4] expressed recently.

Concentration of the Toxic Substance from 'Agenized' Flour

IT was shown by Sir Edward Mellanby[1] that flour, treated with nitrogen trichloride, as it is in the commercial 'Agene' process, is capable of causing fits in dogs, when fed in fairly large quantities. Further investigations have proved that the toxicity is associated with the gluten of the flour, and that the toxicity survives digestion with pepsin and with trypsin[2]. The recent publication in abstract by Reiner *et al.*[3] of particulars of the fractionation and concentration of the toxic substance (mainly prepared by the action of nitrogen trichloride on zein), and the publication by Moran *et al.*[4] of a method of concentration of the toxic substance from zein, make it desirable for us to give our own results.

The process employed involves pancreatic digestion of the gluten followed by passage through resin columns and precipitation with mercury acetate. The gluten was not previously separated from the flour. 70 lb. of flour 'Agenized' at the rate of 125 gm./sack was mixed with 14 gallons distilled water, 500 gm. pancreatin and 500 ml. chloroform. The mixture was adjusted to *p*H 8 with sodium hydroxide and disodium hydrogen phosphate and digested at 37° for 24 hr. The sludge was centrifuged. The recovered gluten was re-suspended in about 3 gallons of water, brought to *p*H 8, and a further 500 gm. pancreatin added. This mixture was digested for a further 48 hr. at 37° and centrifuged. The supernatant from this digestion was usually more toxic than that from the first. It was treated with 2 vol. of absolute alcohol, and the precipitate formed was centrifuged off. The alcoholic liquor was passed through a column containing 2½ lb. of activated 'Zeocarb 215'. When the adsorbed material was eluted with dilute sodium hydroxide, the toxicity was found in the neutral 'fraction' associated with some residual quantities of the acidic and basic amino-acids.

The concentrate so obtained was treated with acid-activated alumina, which removed the acidic amino-acids. After extraction with butanol, a product was obtained which showed four spots on two-dimensional paper chromatography, three of which could be identified as glycine, serine, alanine, and the fourth as glutamine running with an almost indistinguishable unknown substance.

In order to confirm the possibility that this unknown spot was associated with the toxic substance, a quantity of the concentrate was placed in a line along the edge of a large sheet of filter paper and developed with phenol in a direction at right angles to the line. The unknown spot was then located in a long streak parallel to the original position. This part of the chromatogram was eluted with water, and the presence of the toxic substance in it was confirmed by feeding tests.

Later it was found that the unknown spot, which is shown up by the ninhydrin reaction, is accompanied by another, which does not give the ninhydrin reaction, but is detectable in ultra-violet light. As an alternative to the chromatographic separation, which is extremely laborious on a large scale, it was found that the toxic substance could be precipitated by mercuric acetate, added in 25 per cent alcohol solution acidified with acetic acid. The precipitated mercury salt was suspended in water, and hydrogen sulphide was passed to precipitate the mercury. The solution was evaporated to dryness. About 20 mgm. nitrogen of the substance obtained was required to give the toxic symptoms in a ferret. On chromatographic examination it was found that the spot which we believed to be that of the toxic substance was not now accompanied by the fluorescent material. The product has, however, varied somewhat in different preparations, probably owing to an uneven efficiency of the separations, which are not easily controlled. In some cases the two-dimensional chromatogram shows only the one spot; in others, it has been accompanied by others representing histidine, glutamine, asparagine, valine and leucine. Traces of cysteine have also been detected in some preparations. It was later found that in some of the toxic preparations all the chromatographic spots could be accounted for, so that it is likely that the toxic substance, although closely associated with glutamine, does not itself give a ninhydrin colour. This is confirmed by the fact that a similar product from a non-toxic flour also gives the same spots. A further purification on the same scale is being attempted.

We are indebted to Prof. E. C. Dodds for his interest; to Messrs. Wallace and Tiernan for their financial support and permission to publish, and also for assistance with the large-scale digestions, which were carried out in their works; to Dr. D. W. Kent-Jones, for the preparation of the 'Agenized' flours and for constant interest and advice; and to Dr. L. Reiner, of Messrs. Wallace and Tiernan, Newark, New Jersey, for helpful discussions with the senior author during March 1948, in which the methods employed by him at that time were disclosed, and Mrs. S. Simpson for assistance with the toxicity tests.

Influence of Desoxycorticosterone on Glycogen Formation and Glucose Uptake of Isolated Muscle

Isolated diaphragm muscle of rats produces glycogen from glucose especially in the presence of insulin in oxygenated Ringer's solution. This is inhibited by the addition of small doses of desoxycorticosterone[1]. If the muscle works in response to rhythmic stimulation for two hours, glycogen is newly formed and is broken down again. This is also inhibited by desoxycorticosterone[2]. The action of other steroid hormones was also studied. They had either equal effect (progesterone, testosterone) or none (corticosterone, etc.)[3].

We have now studied whether desoxycorticosterone also inhibits the glucose uptake[4] of the surviving isolated muscle.

The diaphragm of normal rats was cut into three pieces immediately after death. One served for the estimation of the starting value of glycogen content. The two other parts were each put in a vessel with 2 c.c. of Ringer's solution with 200 mgm. glucose and 1 unit of insulin per 100 c.c. The vessels were shaken in an oxygen atmosphere at 37° C. for 90 min. To one vessel 0·1 mgm. desoxycorticosterone was added (5 mgm. per 100 c.c.).

Thirty rat diaphragms were tested, and the results are given in mean values with the median error $(\sqrt{\Delta^2/n(n-1)})$. Besides the glycogen formation, the glucose content of the solution was also measured at the beginning and end of the experiment. The methods used were the same as before[1-3].

Mean values

	Glycogen production (30 experiments)	Glucose uptake	NH_3 produced (13 experiments)
Per 100 gm. muscle in 90 min.	272±37 mgm.	457±24 mgm.	8·0±0·6 mgm.
Same, with *addition of* 4·4, 5 or 7 mgm. per 100 c.c. desoxycorticosterone	56± 5 mgm.	200±20 mgm.	9·0±1·3 mgm.

The surviving muscle about doubled its glycogen content in this period, as in former experiments[1]. It took up glucose from the solution, but considerably more glucose disappeared than corresponds to the newly formed glycogen[4]. This occurred in each single experiment and is shown in the mean value, where 272 mgm. glycogen production compares with 457 mgm. glucose consumption.

Desoxycorticosterone totally inhibited the glycogen production; but it decreased the glucose uptake only to about one half. This value seems to correspond to the difference between the glycogen produced and the total glucose consumption of the muscle without addition of desoxycorticosterone. It might be, therefore, that the remaining glucose is metabolized, and that desoxycorticosterone inhibited only glycogen formation. However, it may also be that primarily the permeability for glucose is decreased, and this accounts for the decrease in glucose uptake and in glycogen formation. We intend to study this problem further.

In thirteen experiments, the ammonia production of the surviving muscle was estimated in the solution, using Conway's method[5]. It seemed possible that after the inhibition of glycogen formation, the muscle increased protein breakdown through desamination. No increase of ammonia production was found.

We thank Ciba A.G. for providing us with desoxycorticosterone.

Distribution of Ribonucleic Acid in the Cytoplasm of Growing Cells Studied with Phosphorus-32

THE occurrence of ribonucleic acid in the submicroscopic particles obtained by centrifugation of extracts of organs (granules, microsomes, liponucleoprotein complexes) has suggested the hypothesis that these particulate structures might have a role in the synthesis of proteins, and that they may even be identifiable with the viruses and plasmagenes. This idea implies not only that these particles actually exist in the cytoplasm but also that ribonucleic acid is really part of them. It is possible, of course, that they are artefacts which appear upon homogenization of the cells. Indeed, Kleczkowski[1] and Lauffer[2] have shown that a nucleoprotein, the tobacco mosaic virus, is able to form complexes with different proteins under the influence of small changes in the medium, and it is also known that the distribution of ribonucleic acid among the different fractions separable by ultracentrifugation of a tissue extract depends on the salt concentration of the extraction medium[3]. Brachet and Jeener[4] observed in 1943 that high-speed centrifugation of a piece of frog liver displaced a large part of the ribonucleic acid towards the centrifugal ends of the cells; but this phenomenon was not seen when mammalian liver was used. Furthermore, the conditions under which centrifugation is carried out are quite abnormal (using concentrated sugar solutions of the same density as the tissue).

It appeared that the use of labelled atoms might give some idea as to the distribution of the constituents of the granules in the cytoplasm, when the latter is maintained under strictly physiological conditions. Labelled phosphorus was injected into gravid mice, hen's eggs or into pigeons, the crop glands of which were actively proliferating after injections of prolactin. The mouse embryos, chick embryos or crop glands were removed two hours after the injection of the labelled phosphorus and mechanically homogenized with phosphate buffer at *p*H 7·3 containing 30 per cent sucrose. The extract thus obtained was cleared of nuclei and cellular debris by a short centrifugation at low speed and then fractionated by further centrifugation into three parts: (*a*) the 'pellet' of granules obtained after centrifuging for 14 min. at $13 \times 10^3\ g$, (*b*) the pellet resulting from 60 min. centrifugation at $60 \times 10^3\ g$, and (*c*) the supernatant liquid resulting from (*b*). The specific radioactivity of the phosphorus of the ribonucleic acid was determined by the Schmidt–Thannhauser method as modified by Spiegelman and Kamen[5]. In order to get rid of the inorganic labelled phosphate ions an excess of normal phosphate ions was added and the whole eliminated as ammonium magnesium phosphate. A control experiment showed that the ratio between optical density at 255 mμ and the phosphate hydrolysed by 1 *N* hydrochloric acid in three hours at 100° C. was the same in the case of the solution of mononucleotides studied and of a similar solution prepared from purified yeast ribonucleic acid.

As the accompanying table demonstrates, the specific radioactivity of the phosphorus of the ribonucleic acid of each of the three fractions is quite different (there is a probable error of ± 4 per cent). However, it is still impossible to tell to what degree the labelled phosphorus found in the nucleic acid of the different fractions is a measure of the renewal of nucleic acid molecules or of an increase in their number during the growth of the cells.

Specific radioactivity of phosphorus in ribonucleic acid (in arbitrary units per 100 γ P)

	Supernatant of $60 \times 10^3\ g$	Pellet of $60 \times 10^3\ g$	Pellet of $13 \times 10^3\ g$
Mouse embryo	100	16	75
	124	38	82
	605	223	498
	1365	440	1000
Crop gland of pigeon	316	272	475
	5960	143	5170
Chick embryo	155	97	101
	263	45	37

But an important conclusion can be drawn from the facts just stated. It is that nucleic acid is seen to be at least partially associated with particles, and that these really exist in the cytoplasm of the living cell. It would be difficult to explain otherwise how the radioactivity of the phosphorus of the nucleic acid differs from one fraction to another, for such would certainly not be the case if nucleic acid existed in a free state in the cell, associating with other substances to form granules only as a result of the extraction procedure. The results show further that at least three different fractions of ribonucleic acid exist, as well as at least two kinds of granules which contain it.

It may also be pointed out that it seems quite certain that the differences in specific radioactivity which have been observed are definitely present in the living organism and not merely appearing in the extracts during the various procedures, for the turnover of nucleic acid phosphorus in the extracts is three hundred times too small to account for the differences seen.

The Weiss–Heisenberg Theory of Ferromagnetism and a New Rule Concerning Magnetostriction and Magneto-Resistance

IT is considered an open question[1] whether the Weiss–Heisenberg model or the band model, which is based on the conception of the itinerant electron, is the more appropriate one for the description of ferromagnetic phenomena. On the whole, the original Weiss treatment translated into modern language is surprisingly powerful when compared with numerous later attempts at an improvement.

It occurred to me that arguments for or against the Heisenberg model might be derived from a consideration of the properties of ranges of alloys in which the mean number of Bohr magnetons passes through an integral value. The Heisenberg model leads one to expect that the exact filling up of all lattice-points with an equal number of electrons will make itself felt in some properties of the ferromagnetic alloy. From the point of view of the band theory, however, a singling out of such an alloy from its neighbouring alloys is pointless, there being no reason why this particular alloy should be different from other alloys. We therefore have here a suitable criterion at hand for deciding between both theories.

In order to have a reasonable chance of finding such a singularity at integral values of the mean number of Bohr magnetons, it is, of course, preferable that the alloy components shall be chemically as much alike as possible, and that the lattice structure should be a simple close-packed arrangement.

The above conditions are fully met by a nickel–cobalt alloy containing 33 per cent of cobalt[2], by a nickel–iron alloy containing 18 per cent of iron[3] and approximately by an alloy of composition Ni_3Mn in the ordered arrangement[3]. In the first two of these alloys, the mean number of Bohr magnetons is equal to one, in the third it comes close to one (about 0·95).

From a survey of the available literature[4,5,6], it became at once clear that our criterion leads to alloys having zero magnetostriction, a most remarkable result indeed. For the nickel–cobalt series the agreement between the two critical concentrations at first seemed rather poor. As pointed out by Kühlewein[7], however, the existing very old data on the magnetostrictive properties of nickel–cobalt alloys are not to be trusted, probably due to lack of purity of the cobalt. Control measurements which have been carried out on high purity nickel–cobalt alloys by J. J. Went of this Laboratory have confirmed our expectation[8].

An extended search in the literature further brought to light that at the concentration where $\lambda = 0$ (and accordingly $n_B = 1$), the change in the electrical resistance due to the application of a magnetic field passes through a maximum.

For the nickel–iron series only measurements carried out at room temperature are available[9], and even these are scanty. On nickel–cobalt, however, extensive measurements have been carried out by Shirakawa[10] at various temperatures down to −195° C. At this temperature the effect is very pronounced, and the maximum change observed (16 per cent) is found to occur in alloys with between 30 and 40 per cent of cobalt. At room temperature the maximum is much weaker (only 5 per cent), and at 300° C. it is no longer observable.

It is tempting to speculate a little further on the anisotropy of the magnetostriction as observed by Lichtenberger[11] on single crystals of nickel–iron. Apart from minor discrepancies, Lichtenberger's results can be adequately summed up in the following statement: apparently the absolute value of λ always has a minimum value in the direction where the internal energy also has a minimum value.

An extension of the results obtained above to other cases is difficult and of doubtful value. Alloys of ferromagnetic components, having, in the mean, two Bohr magnetons instead of one, no longer have a close-packed structure, but are cubic body-centred. All the same, on the whole the magnetostriction seems to be small also in those alloys, so there is no contradiction. For alloys of a ferromagnetic component with an unmagnetic component, one does not expect a simple rule like the one stated above to hold, because of the very different character of the components. Indeed, it is found that their behaviour is quite different from that of alloys having only ferromagnetic components.

Alloys like Fe–Pt, where n_B is also found to pass unit value, are subject to phase transformations and therefore difficult to investigate.

It is felt that the observed near coincidences in the nickel–cobalt, nickel–iron and nickel–manganese binary systems, as well as the above provisional rule on the anisotropy of the magnetostriction, may perhaps serve as a starting point for a theory concerning these phenomena.

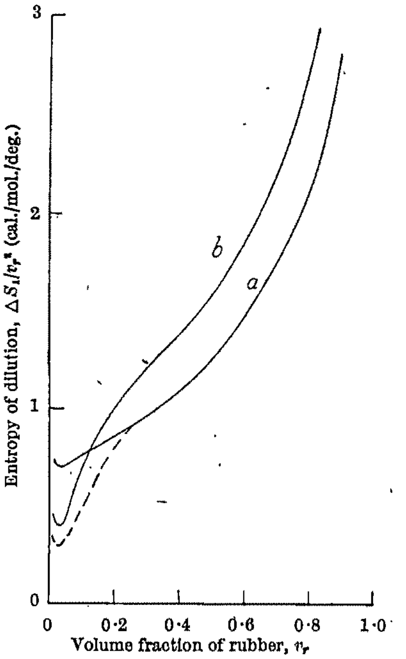
Entropy of Dilution of a Polymer-Solvent System

IN examining the properties of polymer-solvent systems, considerable attention has been given in the last decade to the evaluation of the configurational contribution to the partition function. It has been shown[1] that the greater part of the divergence of these systems from ideal behaviour is due to the vast differences in the sizes and shapes of the molecules of the polymer and of the solvent. This configurational contribution exercises a dominating influence on the thermodynamical properties of polymer-solvent systems. The rubber–benzene system has been most thoroughly investigated experimentally. The theory reproduces the observed behaviour of the free energy, and also the general trend of the entropy at ordinary concentrations (see ref. 1, sections 4.6, 4.9, 4.10 and 6.11); but in very dilute solution, the experimental measurements show a feature which is not reproduced by the theory. This is made clear by the theoretical (*a*) and experimental (*b*) curves shown by the *full* lines in the diagram. In this note, the effect responsible for the dip in the experimental curve in dilute solution is determined; its effect is shown by the dotted curve in the diagram. From this it can be seen that the new theoretical curve reproduces the shape of the experimental curve throughout the whole concentration-range.

In first deducing an unambiguous expression for the combinatory factor, and the various thermodynamical quantities of interest, it was shown[2] that the significant parameter was the number of closest neighbour interactions or contacts which one polymer molecule shares with its surroundings. For simple-chain and branched molecules, the number of closest neighbour interactions zq is given by

$$zq = zr - 2r + 2, \qquad (1)$$

where z is the co-ordination number of the quasi-crystalline model of a liquid and r is the number of segments in a polymer molecule. For very large values of r, appropriate to a high polymer, the ratio of the number of external contacts of a molecule to the number of sites occupied by it is almost exactly $z - 2$. This assumes, as is the case at ordinary



concentrations, that the polymer molecules are spread out and intertwined throughout the system.

There is evidence[3] that in dilute solution the polymer molecules tend to segregate, to coil up and to form clusters. My view has been (see ref. 1, sections 6.3 and 6.6) that the discrepancy, in the region of very dilute solution, between the theoretical and the experimental entropies was due to this change in the configurational properties of the individual polymer molecules as the concentration varied; that it did so through a reduction in the number of contacts of each polymer molecule; and that this gave rise to the observed variation of the heat of mixing of the rubber–benzene system.

Coiling of the polymer molecules in dilute solution implies physically that the number of external contacts is greatly reduced. This reduction will occur over a small concentration-range. Its effect can be seen in the following way. The entropy of dilution for a polymer-solvent system can be written, in terms of the parameters which define the polymer molecule, in the form

$$\frac{\Delta S_1}{R} = -\log(1-v_r) - \frac{r}{r-q}\log\left(1-\frac{r-q}{r}v_r\right). \quad (2)$$

(This is simply equation (4.24) of ref. 1, making use of equation (1) above.) If the right-hand side of this equation is expanded as a power series, the term in v_r vanishes; it is to this fact that the particular form of the entropy in such a system is due. Expanding the right-hand side, we get

$$\frac{\Delta S_1}{R} = \frac{1}{2}\frac{q}{r}v_r^2 + \frac{1}{3}\frac{q}{r}\left(2-\frac{q}{r}\right)v_r^3 + \ldots \quad (3)$$

Thus, the value of the entropy of dilution depends immediately on q/r, that is, on the ratio of the number of external contacts of a molecule to its number of segments. It is clear that if, as the system is diluted with solvent, the number of external contacts of a polymer molecule falls, owing to the fact that it coils up, then the entropy must assume a lower value than it would otherwise have. In fact, to a first approximation, the entropy will be lower than that calculated, assuming the fixed value of q given by equation (1), just in the ratio that the number of contacts has diminished. Assuming that the configurational properties of individual polymer molecules begin to change markedly at about $v_r = 0{\cdot}25$, corresponding to a molar concentration of the order of 10^{-3} or 10^{-4}, the theoretical curve now assumes the form shown by the dotted line in the diagram. The diagram shows that when this effect is allowed for, the theory reproduces the form of the experimental results completely.

The importance and usefulness of this concept of the number of contacts of a polymer molecule had been suggested previously[2,4] in other connexions; it clearly has other applications. For flexible polymer molecules there is self-blocking of some possible configurations owing to the polymer molecule bending back on itself[5,6]. This reduces the number of contacts of each polymer molecule; from the considerations which have been advanced in this note, it needs no elaboration to see that the effect must be very small. The same concept can be used also to consider systems of roughly spherical molecules which differ greatly in size, as is common in biological systems. In this case, the departure from ideal behaviour will be very much less than for a polymer–solvent system which has the same molecular volume ratios. The analysis given in this note also shows that there is no justification for suggesting[7] that the agreement between the experimental and theoretical free energy curves is due to a fortuitous cancelling of errors.

The configurational properties of the system, arising from the different shapes and sizes of the molecules of the polymer and of the solvent, are the dominating influence in the departure of polymer–solvent systems from ideal behaviour. The dependence on concentration of the configurational properties of individual polymer molecules can be adduced to account for the dip in the experimental curve for the entropy of dilution, which was not given by the basic theory used previously.

Metastable States of Nickel

In view of the recent communication by Snoek and Fast[1] on their observation of the metastable states in *well-annealed* nickel, it may be of interest to record a similar effect which was noted in the course of some investigations on nickel magnetostrictive oscillators. These experiments, made just over a year ago, were essentially of a dynamic type, in contrast to the static conditions used by Snoek and Fast.

The specimen was a consolidated stack of laminations mounted on a pin at the central node, and it was excited at its resonant frequency (10·7 kc./s. at room temperature with zero polarizing field) by a beat-frequency oscillator applied to a driving coil closely encircling the stack. The E.M.F. induced by the motion of the stack in a screened 'pick-up' coil

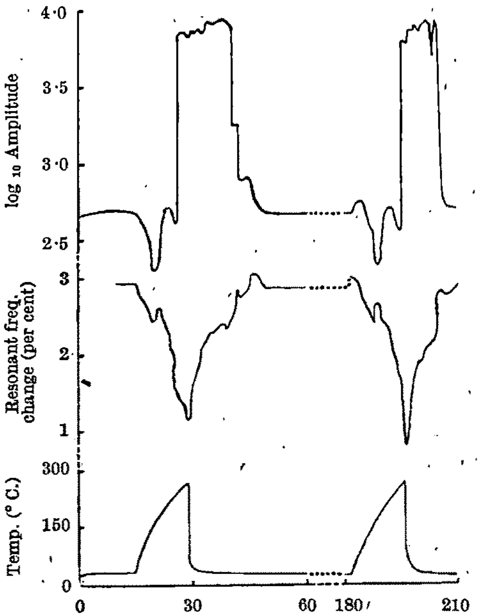

Fig. 1. Onset of metastable state with temperature rise (polarizing field 280 oersteds)

is proportional to the amplitude and also to the square of the dynamic magnetostriction constant, λ, as defined by the relation $\delta p = \lambda \delta H$, where δp is the incremental stress resulting from a small change δH in the applied magnetic field.

Magnetic polarization of the specimen was effected by passing a direct current (maximum value 7 amp.) through additional coaxial coils, the maximum polarizing field being 280 oersteds. At the higher currents used, considerable heat was developed in the polarizing coils, causing a rise in temperature of the stack. The surface temperature was measured by a contact thermocouple.

Typical curves are shown showing the variations with time in the amplitude of motion as the temperature varied, for the case of a laminated bar made from pure *cold-rolled* nickel sheet 0·005 in. thick. It will be seen that following a rapid rise of temperature (brought about by shutting off the forced-air cooling system), there is a large increase in λ, which it is possible to maintain for a period of hours or even days. This effect was not obtained with similar experiments made on a number of nickel alloys.

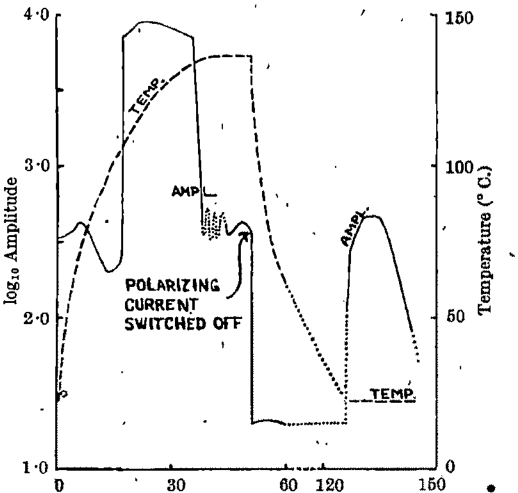

Fig. 2. Recurrence of metastable state after nickel has cooled (polarizing field 200 oersteds)

It may be found that these metastable conditions can be employed for a highly efficient magnetostrictive transducer, which could be used in special circumstances where the higher temperatures do not present any difficulties.

Decay of Thulium-170 and Rhenium-186

THE decay of the 127-day thulium isotope (Tm^{170}), has been previously investigated by Bothe[1], and that of the 93-hour rhenium isotope (Re^{186}) by Goodman and Pool[2]. In both cases absorptio methods were used.

The present investigations were carried out by means of absorption and coincidence techniques, and also by means of a short magnetic-lens β-ray spectrometer.

A summary of our results appears below:

	β-rays	γ-rays
Tm^{170}	1·00 ± 0·01 MeV. 0·90 ± 0·015 0·79 ± 0·03 0·45 ± 0·05	82·6 ± 0·7 keV. 200 ± 10 440 ± 20
Re^{186}	1·095 ± 0·010 MeV. 0·945 ± 0·015 0·64 ± 0·030	132 ± 1 keV. 275 ± 5

A more detailed account of this work will appea shortly.

We wish to express our appreciation of the hel given by members of the Atomic Energy Researc Establishment, Harwell, where the active sample were prepared by slow neutron irradiation in th low-energy pile.

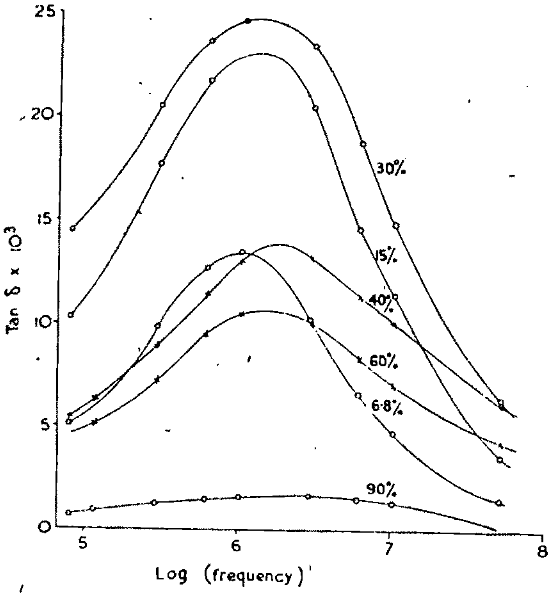
Dielectric Absorption in Crystalline Long-Chain Ketones

FOR dilute solid solutions of long-chain pola compounds in paraffins, it has been shown that th rotational transitions of the polar molecules from one position of minimum potential energy to anothe lead to dielectric absorption of the Debye type[1,2]. A theoretical study has also been made[3,4] of the dielectric properties of pure crystalline compounds, in which dipolar interaction is an important factor.



Dielectric absorption at 20° C. for a range of concentrations of laurone in *n*-hexacosane

In order to investigate the effects of dipolar interaction, it seemed desirable to make dielectric measurements with mixtures containing a gradually increasing proportion of polar molecules. The accompanying graph shows the frequency / tan δ relationships for a series of concentrations of the ketone, laurone ($C_{23}H_{46}O$), in a non-polar solvent, *n*-hexacosane. The measurements were made at 20° C., and over the frequency-range, 60 kc./s. to 50 Mc./s. It is seen that the dielectric loss at first increases with increasing concentration but later decreases, pure laurone giving negligible loss within this range.

With concentrations up to at least 15 per cent, the majority of the laurone molecules are probably surrounded by non-polar solvent. The rapid increase of the maximum tan δ with concentration in this ange suggests that solute molecules thus situated are able to perform rotational transitions leading to dielectric absorption in an alternating electric field. A small proportion of the ketone molecules, however, occupy adjacent positions in the crystal lattice, and he resulting dipole interaction probably causes a very high energy difference, *V*, between equilibrium positions. The probability of finding such molecules in a higher equilibrium position is thus small, and they therefore contribute little to the polarization. As the concentration of laurone increases, the proportion of adjacent molecules increases rapidly, the effect on the polarization being indicated by the dielectric absorption results given. It is probable that pure crystalline laurone provides an example of the type treated theoretically by Fröhlich[5], in which, even at room temperature, $kT \ll V$, and there is no dielectric loss of the Debye type. Similar results were obtained with the ketones, myristone ($C_{27}H_{54}O$), palmitone ($C_{31}H_{62}O$), stearone $C_{35}H_{70}O$) and 22-tritetracontanone ($C_{43}H_{86}O$).

In contrast to the ketones, several long-chain esters gave strong absorption of the Debye type. The maximum tan δ and frequency values for three such compounds are given in the accompanying table.

Ester	Tan δ (max.)	Frequency (max.)
Dodecyl laurate, $C_{24}H_{48}O_2$	$1 \cdot 4 \times 10^{-2}$	3 Mc./s.
Dodecyl myristate, $C_{26}H_{52}O_2$	$4 \cdot 0 \times 10^{-2}$	600 kc./s.
Cetyl palmitate, $C_{32}H_{64}O_2$	$1 \cdot 5 \times 10^{-2}$	100 kc./s.

Thus, with these esters, the energy difference between equilibrium positions is probably less than in the ketones of corresponding chain-length, and a significant proportion of the molecules are to be found in the second position. This suggests that dipole interaction in the esters is less than in the corresponding ketones.

Potassium and Neuromuscular Transmission

IN a study of the effects of ions on the rat diaphragm, it has been found that denervated preparations are much more sensitive to potassium than the normal diaphragm stimulated through its nerve. A dose of potassium, for example, exposure to a concentration of 0·08 per cent in Krebs's solution, which has no depressant action on normal muscle, may completely depress the response of denervated muscle to electrical stimuli while its response to acetylcholine remains. Observations have now been made on diaphragms denervated functionally by curare, which prevents the action of acetylcholine, or by lack of glucose, which prevents its synthesis or release. The effect is the same in both cases. If now, however, the experiment is reversed and the potassium added first, it is found that after curare, or through lack of glucose, which abolish neuromuscular transmission, the muscle has become inexcitable. The exact cause of this somewhat dramatic finding is not certain.

An obvious suggested explanation of these facts might be that potassium and curare have a synergic action, or that acetylcholine and potassium oppose each other. Another explanation would be that the potassium does, in fact, render the muscle inexcitable to direct stimulation in all cases, but it can remain excitable to nerve stimulation only. This explanation is supported by preliminary observation that, although after potassium the muscle contracts normally, its resting potential is reduced by one third, as shown also by Boyle and Conway[1], and its action potential is negligible. This latter observation is in accordance with that of Brown and Euler[2], that action potential may be reduced by potassium while the muscle tension is increased.

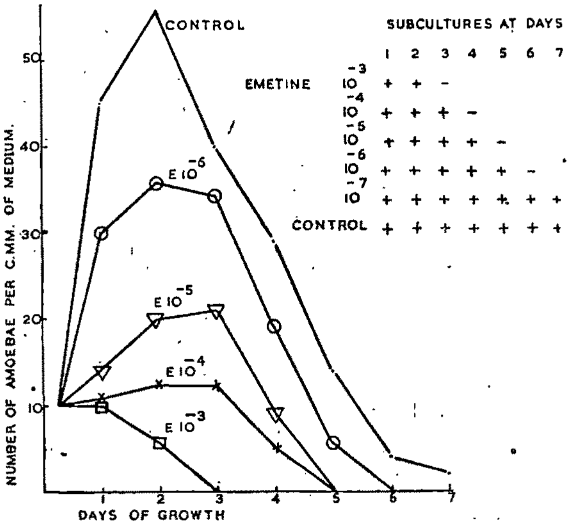
Nature of the Action of Emetine upon *Entamœba histolytica*

THE fact that emetine exerts a powerful toxic action upon *E. histolytica*, *in vivo* and *in vitro*, has long been established[1,2]. The mechanism of this action, however, is far from clear[3]. Furthermore, the end-point of toxicity of emetine to *E. histolytica* is variable *in vitro*, depending upon such factors as the nature and reaction of the medium, time of observation, and composition of the bacterial flora which necessarily accompanies the growth of the amœba in culture[2,4].

In the experiments reported below, emetine hydrochloride was added (*a*) to cultures of *E. histolytica* in a basic medium of horse serum, rice starch and saline buffered with phosphate to *p*H 7·2, and (*b*) to suspensions, prepared from such cultures, with a cell density of 150–300 per c.mm. Ten strains of *E. histolytica* were used, each having been isolated originally from cysts in human fæces. One strain (*M*) was grown with *Bact. coli* plus *Cl. welchii*; the other strains included in their bacterial flora non-lactose-fermenting coliforms, *Ps. pyocyaneus*, enterococci and *Clostridia*. Acting in the basic medium, emetine did not inhibit the growth or respiration of these bacteria, individually or in combination.



At *p*H 7·2, emetine (in dilutions ranging from 10^{-6} to 10^{-7}) sterilized cultures of *E. histolytica* in three to seven days. A study of growth curves showed that this effect was due to a reduction of the propagation-rate (see graph). No division occurred at dilutions of 10^{-3} to 10^{-4}; at higher dilutions there was a progressive increase in the rate of division, and dilutions higher than 10^{-7} showed no difference from control cultures. The addition of cysteine (0·02 per cent) did not antagonize the action of emetine.

When emetine was added to suspensions of *E. histolytica*, there was no change in the morphology of the cells, and subculture of washed cells was always positive during the first four hours. Thereafter, at dilutions of 10^{-3} or less, emetine produced conspicuous degenerative changes in 80–100 per cent of the cells, clearly shown in fresh or iron–hæmatoxylin preparations. Bi-nucleate or dividing cells were absent, and, after 48 hours, subculture was negative. With higher dilutions, there was a proportionate decrease in the number of degenerate cells; dividing cells were present and subcultures made after 48 hours were positive, as in the controls. The morphologica changes observed were, in order of appearance: loss of motility, vacuolation, coarse granulation and central retraction of cytoplasm, loss of nuclear differentiation, and disintegration. These morphologica changes were not specific for emetine, since cells comparable in appearance though not in numbers were seen in the control suspensions, especially after 24–48 hours, when the death-rate rose sharply.

From these observations it would seem that emetine does not exert an immediate toxic action upon *E. histolytica* in the fashion of a general protoplasmic poison. It does, however, have an 'amœbostatic' effect, absolute at a dilution of 10^{-3} but still evident at 10^{-7} with some strains. Cultures growing in the presence of emetine are sterilized more rapidly than controls for the reason that the cell count reaches a lower maximum, and the culture dies sooner. The end-point of survival of such a culture is determined by the ratio of propagation-rate to natural death-rate of the cells. The cell envelope remains intact, and motility is preserved in the majority of the cells for four hours in the presence of emetine. Surviving cells, transferred from an emetine medium after 24–48 hours, grow normally Emetine does not produce a definite stage of mitotic arrest, and its action is not antagonized by cysteine an —SH donor. It seems likely, therefore, that emetine acts upon *E. histolytica* by a highly specific interference, in proportion to its concentration, with some essential cytoplasmic reaction at a phase in the growth of the cell prior to cell division.

Effect of the *Striga* Germination Stimulant on Extension Growth on the Roots of Peas

THE seeds of *Striga hermonthica*, like those of certain closely allied parasites, will normally only germinate after they have been treated with a stimulant that is released from the roots of a large variety of species[1]. The situation suggests that the parasite seed is supplied from actively growing hos roots with a hormone which is normally required i germination but which is not synthesized by the seed[2]. Moreover, the hormone only acts at a comparatively late stage in the germination process, anc then it has the effect of promoting the extension o the cells of the radicle. When the radicle emerges, a first there is no division at the apex, and the increase in length is apparently due primarily to cell extension Thus the hormone may be one that promotes cel extension in the root of *Striga*, and since it is produced from a large variety of species it may be one that stimulates extension growth in roots in general[2]

This possibility has been investigated by treating segments of pea roots taken from the extending zone with various dilutions of a solution of a concentrate of the hormone. The segments are obtained by cutting out of intact roots the zone extending from 1·5 to 3·0 mm. from the tip. Observations can be made rapidly with this material, and extension growths in the root can be studied independently of the tip, both considerations being of importance since the available evidence suggests that the hormone is produced in the tip and that it is highly labile. In the normal procedure, the segments after they are excised are placed on sintered glass disks standing in the experimental solutions, twenty segments being allocated to each disk. After incubating for 18 hr. at 25° C. in the dark, the segments are examined microscopically, and the length and breadth of each is measured against a calibrated micrometer eyepiece. Each figure given below is the mean of twenty observations made with each treatment.

The mean lengths and breadths (mm.) given with various dilutions of the concentrate and with water are presented in Table 1, which also includes the calculated percentage increases in volume over the original volume at the beginning of the experiment. It will be noticed that at a concentration of 10 mgm./litre the preparation of the natural stimulant gives a volume increase considerably greater than that of the control with distilled water (in Table 1 the differences in the group of means for breadth are not significant, but those for length are highly significant).

Table 1.

Concentration (mgm./litre)	Length	Breadth	Percentage increase in volume
0 (Control)	2·17	1·10	55·9
100	2·25	1·10	61·5
10	2·35	1·13	81·1
1	2·12	1·11	57·8
0·1	2·14	1·10	53·7
0·01	2·15	1·11	60·0

The stimulant involved in the germination of the *Striga* seeds has not been isolated in the pure state; but it has been found that concentrates of the natural stimulant that give germination at high dilutions contain pentose sugars which are probably not aldopentoses, and that D-xyloketose may induce germination at lower concentrations than the purest preparations of the natural stimulant that have so far been made[3]. Thus it is probable that the natural stimulant is at least similar to D-xyloketose, and the effect of this sugar on the extension of pea root segments has therefore been examined in some detail. The results of two experiments with xyloketose conducted with the technique described above are shown in Table 2. It is evident that at appropriate concentrations of D-xyloketose, increases in length and breadth, and therefore of volume, are given that are considerably greater than the corresponding increases given with water. (The differences in the means for length are highly significant for both *A* and *B*; for breadth they are not significant for *A* but highly significant for *B*.) Moreover, it may be noted that stimulation of extension growth is given with concentrations so low as 0·1 mgm./litre.

Table 2

Concentration (mgm./litre)	Length		Breadth		Percentage increase in volume	
	A	*B*	*A*	*B*	*A*	*B*
0 (Control)	2·33	2·15	1·08	1·10	65·1	51·6
1000	2·42	2·34	1·07	1·15	70·9	79·1
100	2·39	2·22	1·08	1·14	70·7	68·6
10	2·48	2·37	1·09	1·15	80·5	83·3
1	2·59	2·30	1·12	1·13	99·1	71·6
0·1	2·38	2·22	1·09	1·10	73·9	56·8
0·01	2·31	2·20	1·09	1·10	67·3	55·9

All results obtained with the natural stimulant have shown some increase in breadth at certain concentrations of the stimulating solution. In certain instances the increases in breadth are not statistically significant; but they have been observed repeatedly, and they are a characteristic of the stimulation due to this hormone. With pea-root segments, heteroauxin may give a slight increase (less than with D-xyloketose) in length at a concentration of 0·001 mgm./litre, but increases in breadth have never been observed. Indeed, the breadths of the treated segments are always lower than those of the water controls for all concentrations of heteroauxin greater than 0·0001 mgm./litre. The differences between the volumes of the segments treated with heteroauxin and those of the water controls are rarely as great as 10 per cent, whereas the corresponding differences between those treated with D-xyloketose and the controls are rarely less than 30 per cent, and may be as high as 60 per cent at the appropriate concentrations.

Finally, so far as we know, this is the first record of a stimulating effect on the growth of plant tissues of a simple sugar in concentrations of less than 10 mgm./litre.

We wish to express our thanks to the Colonial Products Research Council for financial support in this investigation, and to Mr. A. G. Long for preparing some of the samples of D-xyloketose that have been used.

Free Amino-acids in the Hæmolymph of *Calliphora erythrocephala* Meigen

The recent publication by Raper and Shaw of an analysis of the amino-acids of the hæmolymph of the nymph of *Aeschna cyanea*[1] prompts us to report a similar investigation we have carried out upon the hæmolymph of the larva of *Calliphora erythrocephala*. The larvæ used for this study were inbred descendants of a single female and were reared on ox liver at 25° C. for 4–5 days. The amino-acids were separated and identified by paper partition chromatography.

About fifteen larvæ were washed with water and then each larva was bled on to a small strip of filter paper by puncturing the heart with a needle. These papers were dropped into 90 per cent alcohol, and so a clear solution of the free amino-acids was obtained; the protein constituents remained adsorbed on the filter paper. This solution was concentrated to about 0·15 ml. on a water-bath or, preferably, at room temperature *in vacuo*, and then 20-c.mm. samples of this were used for analysis. One- or two-dimensional chromatographic analysis was carried out by the ascending technique[2] using phenol ammonia, *n*-butanol-acetic acid (4/1, by volume), collidine–lutidine (1/1, by volume) as solvents. The papers were dried and finally developed by spraying with ninhydrin. The accompanying table lists the amino-

Amino-acids	Proportion	Amino-acids	Proportion
Alanine	2·5	Phenylalanine	0·5
Tyrosine	2·0	Glycine	0·3
Proline	1·0	Leucine	0·3
Valine	1·0	Lysine	0·2
*iso*Leucine	0·7	Serine	0·2
Histidine	0·5	Aspartic acid	0·1

acids identified and gives an estimate of their relative proportions by weight.

There are several interesting features about the results of this analysis. Phenylalanine has not previously been found in hæmolymph in other larvæ, for example, *Dytiscus marginalis*[3], *Oryctes nasicornis*, *Melolontha vulgaris*[4] or *Aeschna cyanea*[1]; but in this case it occurred in appreciable proportion. It is of interest to note that Goldberg and de Meillon have recently shown that phenylalanine is essential for the growth of the larvæ of *Aedes ægypti*[5]. The same workers showed that cystine and methionine were necessary constituents of the diet. It seems surprising that neither of these amino-acids has, as yet, been detected in any hæmolymph.

Florkin and Duchateau[3] have reported the tyrosine concentration in the hæmolymph of *Dytiscus marginalis* as 117–168 mgm. per cent. Taking their value of 106 mgm. per cent amino-acid nitrogen, our results would correspond to about 150 mgm. per cent tyrosine, a value comparable with their result. Such a concentration seems abnormally high when compared with the solubility of tyrosine in water (45 mgm. per cent at 25° C.). The proportion of tyrosine reported in our table was confirmed by direct comparison with the valine using spot-dilution technique.

The presence of both leucine and *iso*leucine was shown by separation of the 'leucine fraction' by one-dimensional chromatography; then, after extraction from the paper, the two were separated by further chromatography using benzyl alcohol. The trace of histidine was detected by treating the appropriate region of the paper with diazotized sulphanilic acid in sodium carbonate solution. Histidine then shows as an orange-red coloured spot.

This work is part of an investigation of the nutrition of tissues. It is hoped to study the metabolism of both insect and mammalian tissues *in vitro*.

Use of Wetting Agents against Heath and Undergrowth Fires

Suggestions have been made[1] that by the addition of wetting agents an economy can be achieved in the use of water in fire fighting, particularly with heath and undergrowth fires. Preliminary experiments which we have recently completed indicate some of the probable limitations of this proposal, and also suggest fields in which it might have some practical use. The combustible materials used were ling (*Calluna vulgaris*), bracken (*Pteridium aquilinum*) and purple moor grass (*Molinia cœrulea*); the samples were provided by the Forestry Commission at the end of the winter and after a long dry spell, so that they were in their most dangerous condition from the point of view of the forest fire-fighter.

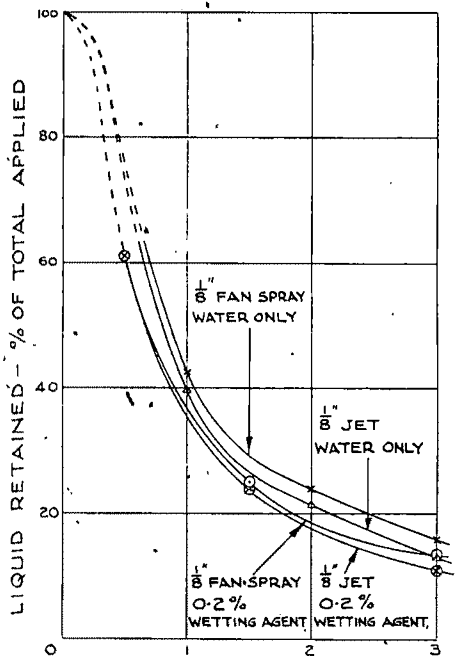
Three series of experiments were carried out: (i) extinction of fires; (ii) prevention of spread of fire; and (iii) wetting of dry materials at normal temperature (that is, without fire).

In each series a comparison was made between the effectiveness of water and that of a solution of each of three commercial wetting agents (one non-ionic and two anionic), and of application in the form of a jet and as a spray. The wetting agents were used in 0·2 per cent aqueous solution, since increases in concentration beyond this point did not greatly reduce the surface tension with any of the agents used.

For the fire extinction experiments, the material was spread on a circular area of ground, and was ignited at the centre. The fire was attacked when its diameter was approximately half that of the circular area. No significant difference was observed between water and the wetting agent solution, either in the time taken to extinguish the fire or in the amount of liquid used.

For the second series of experiments, a 6-in. layer of *Molinia* was spread in a rectangular colander, 4 ft. long × 2 ft. wide. Liquid was applied by means of a spray for a predetermined period to one half of the specimen, the other half being covered. At the end of the wetting period, the cover was removed from the dry half, which was then ignited. It was found that the quantity of liquid required to prevent the advance of flame from the dry to the wet zone was half as much with the wetting agent solution as with water.

In the third series of experiments, a 6-in. layer of each of the materials investigated was placed in the colander, and liquid was applied for a given period as either jet or a spray, and the quantity retained in the sample was determined by difference in weight before and after application. Typical



Retention of liquid in samples of ling

Results with ling are shown in the accompanying graph; little difference was revealed between the behaviour of wetting-agent solutions and water.

Within the scale of the experiments it was apparent hat, though wetting agents gave no advantage in ire extinction, they may well prove to be of value in ontrolling heath fires by the technique of wetting he unburnt materials ahead of the fire. This is reasonable in view of the fact that, whereas the small quantities of wetting agent used can have little effect upon the thermal properties of the water, the reduction in surface tension which they bring about is likely to result in improved dispersion within the ombustible material even when it causes no appreciable change in the total quantity of liquid retained.

It is intended to examine further the efficacy of wetting agents in similar materials of different specific urface.

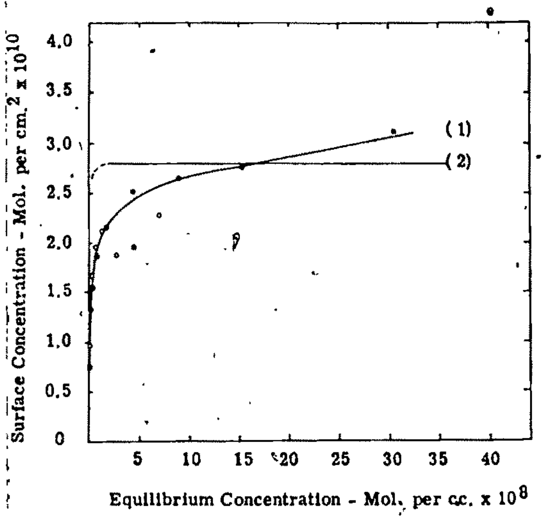
Measurement of the Adsorption of Surface-Active Agent at a Solution – Air Interface by a Radiotracer Method

The adsorption of a water-soluble surface-active agent at a solution – air interface has been measured by taking unique advantage of the soft beta radiation from the radioactive isotope of sulphur, S^{35}. The method depends upon the fact that, because of 'self-absorption' of the radiation by the solution, the amount of radiation escaping from a solution of a compound containing this isotope comes principally from that fraction of the sulphur which is near the surface. Since the molecules of a surface-active agent are preferentially adsorbed at the interface, the radioactivity above a solution containing such an agent labelled with radiosulphur should be higher than the activity from a solution (for example, of sodium sulphate) in which no surface adsorption occurs.

To investigate this idea experimentally, di-*n*-octyl sodium sulphosuccinate ('Aerosol OTN') and sodium sulphate were each synthesized with sulphur-35 procured from the U.S. Atomic Energy Commission). A pure 2–3-mgm. sample of the surface-active agent was secured by five recrystallizations from alcohol – water solutions. Activity measurements were made by placing a mica-window bell-type Geiger counter over small open pans containing the solutions. Measurements were carried out on solutions of the sulphosuccinate and of sodium sulphate having identical concentrations and specific activities. Since the sulphate is not adsorbed at the interface, a comparison of the radioactivity of its solution with that of the surface-active agent permitted a calculation of the amount of agent adsorbed in the interface.

The experimental results showed that the radiotracer technique permitted a successful quantitative determination of the adsorption. Depending upon the specific activities and the concentrations, the counts per minute (c./m.) over the solutions of agent were 1·1 to 20 times those of the corresponding sodium sulphate. For example, in one case the sulphosuccinate solution showed 2,360 c./m., the sulphate solution only 323 c./m. Measurements of some thirty-five different solutions covering a range of specific activities (1×10^{12} to 5×10^{9} counts/min./mole) and of concentrations ($0 \cdot 1$ to 150×10^{-8} moles/c.c.) produced a well-defined adsorption isotherm. It is shown in the accompanying graph, along with an isotherm calculated by the conventional Gibbs equation from surface tension measurements covering the concentration range 4 to 50×10^{-8} moles/c.c. The radioactivity measurements suggested that, after the agent had formed a unimolecular layer, a further increase in bulk concentration caused further adsorption at the interface.



Adsorption isotherm for aqueous solutions of di-*n*-octyl sodium sulphosuccinate. The radioactive isotherm, Curve No. 1, continues without change of slope to a concentration of 150×10^{-8} mol. per c.c., at which point a surface concentration of $5 \cdot 5 \times 10^{-10}$ mol. per cm.² is indicated. The surface tension isotherm, Curve No. 2, remains horizontal to the critical concentration (65×10^{-8} mol. per c.c.). (Temperature, 24° C.)

An interesting aspect is that the rate of adsorption was followed in the low-concentration ranges. The method promises to be useful for studying the kinetics of such adsorption processes.

The radiotracer method outlined above seems to be generally applicable to surface phenomena involving adsorbed layers, either mono- or multi-molecular in nature. Although this note describes the use of sulphur-35, it is evident that other radio-isotopes having sufficiently soft radiation, such as carbon-14, calcium-45, iron-59, etc., could be employed. Moreover, the method appears to open considerable possibility for examining interaction in surface layers. For example, by using labelled sulphate, the adsorption of sulphate ions in the surface layer in a solution containing both cetyl pyridinium chloride and sodium sulphate has already been measured. The application of the method to the study of surface phenomena in bubbles and in systems containing several surface-active materials is under consideration.

Quantitative Chromatographic Analysis of Tetra-, Tri- and Di-methyl Fructoses

In a recent report by Gilbert and Stacey[1] on the constitution of a bacterial levan, these authors state that a convenient chromatographic technique for the quantitative analysis of tetra-, tri- and di-methyl fructoses had so far eluded them. We have devised a partition chromatogram giving quantitative results in the analysis of mixtures of 1 : 3 : 4 : 6-tetramethyl, 1 : 3 : 4-trimethyl and 3 : 4-dimethyl fructoses which is applicable to the study of methylated fructosans based on these sugars. (3 : 4 : 6-Trimethyl fructose has also been examined; but certain difficulties, not yet overcome, arise in analytical separations involving this sugar.)

In principle, the method resembles the separation of methylated glucoses devised by one of us[2], but it differs in practice in two important respects. First, the partitions of the sugars concerned between organic solvents and water necessitate use of a different series of solvents for the mobile phase; and secondly, 1 : 3 : 4 : 6-tetramethyl fructose has appreciable volatility at reduced pressures, both in the dry state and in concentrated solutions, but not in dilute solutions.

The essential steps in our method are as follows. (1) The solution of the sugars is extracted ten times with its own volume of chloroform. The chloroform phase is concentrated (bath temp. 30°) to 50 ml. (no loss occurs). The chloroform is then displaced by distillation with toluene at low temperature (final volume about 50 ml.). This is pipetted on to a silica – water column prepared from a slurry of silica, containing half its weight of water, and toluene.

(2) The tetramethyl fructose is eluted by passing sixteen column-lengths of toluene containing 0·33 per cent of ethanol. The eluate is concentrated (30° C.) to 50 ml. and extracted eighteen times with 50-ml. lots of water, and the combined water phases made up to a known volume. The sugar is then estimated colorimetrically, taking an aliquot of the water phase containing approximately 0·4 mgm.

(3) The water phase from (1) is evaporated to dryness (30° C.), the residue dissolved in a little chloroform and this solution pipetted on to the column. The total trimethyl fructose is then eluted by means of eight column-lengths of chloroform containing 5 per cent (v/v) of *n*-butanol. The eluate is evaporated to dryness (30° C.), some water being added to aid removal of the butanol. The residue is dissolved in ether and this solution evaporated to dryness in a tared evaporation-flask[2]. The dried sugar is then weighed.

(4) Dimethyl sugars are extracted from the column by methanol. This solvent is evaporated, and an ethyl acetate solution of the residue is evaporated and weighed as for the trimethyl sugar.

Recoveries for all three sugars are of the order of 98 per cent (scale of working 100–1,500 mgm.). In every instance the sugars were shown by paper chromatography[3], optical activity and analysis to be pure. A full account of this work is in preparation.

The Teaching of Biology in Schools

I was surprised at the warmth of the hostility with which Prof. Graham Cannon reviewed my pamphlet "Social Biology for Sixth Forms" in *Nature* of April 9, p. 577.

The problem which my paper attempts to answer is this. Supposing that a headmaster will allow a biologist two periods a week to lecture to sixth-form boys specializing in history, classics, mathematics or modern languages, what should he attempt? In my view the answer to this question must take account of three things.

First, the interests of these boys are mature interests. They want to put the questions to a biologist that an adult would ask. Secondly, if biology is worth a place in their education at all, it is because it has implications which affect their philosophy, politics and understanding of history and world problems of the day, such as soil erosion or food supplies. Thirdly, as anybody who knows sixth-form time-tables must be aware, it is unrealistic to expect more than two or three periods a week for such a course, and the time must be carefully used. If the boys have not done any practical biology at an earlier stage—and I should agree with Prof. Cannon in deploring this—it is useless to start here, and unlikely to impress them with the importance of the subject. Of course, one cannot deal exhaustively with the many applications of biology to human affairs in the time available; but one can, as I have shown in practice, arouse interest in the work of biologists which bears on social problems, indicate the kind of answers they would give, and send the boys out keen enough to follow up the work by reading for themselves, and free from some of the superstitions and prejudices with which otherwise reasonable people sometimes approach psychology, heredity, evolution, the birth-rate, intelligence-tests and so on.

Prof. Cannon attacks my course first on the ground that it covers too large a field, and then objects strongly to the idea of selecting some aspects for more detailed treatment than others. The idea that the interests of the class should be a guide as to which problems one pursues comes as a novelty to him, apparently, as in his opinion the order of the course (as laid down by T. H. Huxley, significantly!) must not be disturbed. Later in his review it becomes clear that his eyes are really on examinations rather than education, and, of course, the need to adhere rigidly to a given syllabus is one of the few major drawbacks to an examination system.

The criticism that a course of biology should be based on adequate practical work, natural history and comparative anatomy and embryology is, of course, unanswerable when the biology students, with whom Prof. Cannon deals, are under consideration; but completely impracticable for the history and classical scholars with whom, one suspects, he has very little contact. A good deal can be done by demonstration; they are shown the chromosomes, and the look of an F_2 generation of *Drosophila*, or plankton samples, and they value the experience. But to ask that they should learn the technique of *Drosophila* culture, or that they should be provided with microscopes and personally record the various links in the food-chain of the herring, is unrealistic for the non-specialist.

I should also deny that a course of this kind encourages boys to learn "whole passages or whole problems by heart on the chance of getting a question on them in the examination". In practice it is designed to make them think, and relate theoretical and applied biology to the problems of their time and to their other school subjects. I do not, of course, claim that my outline syllabus is the only answer, or necessarily the right one. It is the result of only fourteen years of experiment in one school. But I am sure that something of the sort is well worth while, and that professors of any of the biological sciences could help by making constructive suggestions as to what scientific ideas the future Civil Servants, lawyers, industrial leaders or clergy of Great Britain should be made aware of. It must be remembered that most of these will come from the sixth forms of our grammar schools, and that for many of them a course of this kind will be the last formal science teaching they will receive. Prof. Cannon does not, however, make constructive proposals.

The accusation that there is too much emphasis on what Prof. Cannon calls 'Neo-Mendelism' is based on a misreading of my paper. The second term's work is not "devoted very largely to a study of Mendelism", but centres on evolution, and embraces also the study of population growth, variation and environmental influences and extinction. When Prof. Cannon writes, of Mendelism, "It is easy to teach, what is certain", I leave it to those who have experience of teaching even highly intelligent non-specialists to judge whether my course or Prof. Cannon's review is the more 'fantastic'.

ERIC LUCAS

The College,
Winchester.
April 25.

MR. LUCAS in his original pamphlet is emphatic that his proposed syllabus is for sixth-form boys specializing in classics, history, mathematics: in fact, in anything other than natural science. Now in the third paragraph of his letter above, he says that if these boys have "not done any practical biology at an earlier stage . . . it is useless to start here". I can only take this to mean that unless these arts students have done some elementary biology in their earlier years at school and so done some *practical* biology, his syllabus for the course of study at the sixth-form level is useless. Is he assuming, therefore, that in these enlightened days all boys, whatever subject they may ultimately specialize in, have had a groundwork in the elements of biology in their early school days ? This may be so at Winchester ; but does he not know that, in the greater number of secondary grammar schools in which biology is taught at all, it is only taught on the science side, and in many of these schools is only dealt with in the sixth form ? His pamphlet, as I pointed out, "purports to deal with the way in which biology and social biology at that can be introduced to a sixth form who have done no biology before"—not the sixth form of any particular school but presumably at any secondary grammar school. That is the way in which I maintain his pamphlet will be interpreted and that is why I criticize it.

But also perhaps I have been guilty of inaccuracy in my review because Mr. Lucas seems to have deduced that I would insist on practical work in the type of biology course he is considering. I did not, however, say this. I merely pointed out that a university professor had the advantage of adequate time for practical work guided by a bevy of demonstrators. If time is short (and nobody disputes this as regards Mr. Lucas's course) then practical work is the last thing I should insist upon. Why, almost as much time can be wasted over practical work in biology as over field-work in botany ! By all means have as many demonstrations as possible, as Mr. Lucas suggests, but heaven forbid that I should ever be called upon to demonstrate an F_2 generation of *Drosophila* to any class, sixth form or otherwise, let alone teach these same boys how to culture the annoying little creatures. No, if I had two periods a week for one year at my disposal and an intelligent sixth form, then, always remembering that the boys had done no biology before and also that the time must be carefully used and not frittered away in snippets here and snippets there, I feel that I could use that time profitably by talking about the *elementary* facts of biology—giving the students some idea of what an organism is, particularly what a human organism is and its relation to its surroundings. This would then enable these boys later on to develop their ideas on these foundations, to ask themselves and others questions that were of importance and not mere trivialities. Mr. Lucas says that his sixth-form boys "want to put the questions to a biologist that an adult would ask". They may want to : but are they equipped to do so ? When they have been given the foundations of the subject they certainly can, if they are intelligent, ask valuable questions ; but until then it will be more by luck than judgment if they manage to avoid the type of inanity with which we are so familiar in our first-year students—and, after all, our first-year students are only glorified sixth-formers. That is why, by the way, I may not be so unfamiliar with the type of student that Mr. Lucas deals with as he appears to imagine.

Then he reproaches me with having an eye on examinations—but why not ? I have had plenty of experience of how schools *do* cater for examinations—especially those for open university scholarships. We all know of the irrational scramble for scholarships among schools, and this all involves catering for examinations : so why not assume that this sixth-form 'culture' is encouraged with one eye on the examinations ? What about this general knowledge paper which it is proposed to introduce into the new examination ? Mr. Lucas's syllabus is just the sort of thing for this paper : and who suggested it ?—Was it the schools or the examining boards ? It was certainly not the latter in this part of the country.

Finally, I am sorry that Mr. Lucas finds genetics a difficult subject to teach. I can only repeat what I said at the meeting of the British Association at Brighton last year, referring to this aspect of biology, "despite the profundities of the Neo-Mendelians, it is still possible to deal with this matter adequately in a few lectures".

But why should Mr. Lucas worry over such a trifle ? As his original pamphlet points out—if a subject is too difficult for the student or the teacher, just drop it and go on to something more entertaining.

Department of Zoology,
University of Manchester.

INELASTIC SCATTERING OF PROTONS BY MAGNESIUM AND ALUMINIUM

By E. H. RHODERICK
Cavendish Laboratory, Cambridge*

THE inelastic scattering of protons by some light elements has been investigated experimentally, using 4·5-MeV. protons from the Cambridge cyclotron. The energy spectrum of the scattered protons was determined by using a proportional counter in conjunction with absorbing foils. The experimental arrangement was similar to that used by Dicke and Marshall[1], except that provision was made for observation of the scattered protons at angles between 20° and 160° at 10° intervals. Only proton groups corresponding to excited states less than 2·5 MeV. above the ground-state were able to reach the counter. The resolving power was improved by a factor of four over that obtained by Dicke and Marshall by the simple expedient of rotating the scattering foil through 90° from the position adopted by them, which minimizes the effect of target thickness. Under these conditions the resolving power was about 250 keV. for inelastic groups of equal amplitude.

The spectrum of the protons scattered by magnesium is shown in Fig. 1. The first inelastic group corresponds to a Q value of $-1\cdot36 \pm 0\cdot03$ MeV., and in view of its large amplitude is almost certainly associated with the predominant isotope, magnesium-24. The excited state of the residual nucleus which is involved is probably that which is responsible for the 1·38-MeV. gamma-ray emitted following the beta-decay of sodium-24, which has been measured very accurately by Siegbahn[2]. The Q value of this group remained constant with angle to within ± 0·015 MeV., which represents the relative error in the measurements at different angles. The second inelastic group corresponds to an excited state 1·82 ± 0·04 MeV. above the ground-state, and in view of its small amplitude may belong to an isotope other than magnesium-24. The presence of an inelastic group at this energy has recently been confirmed by Bush and Fulbright[3], though these authors state that its amplitude is comparable with that of the first inelastic group for higher bombarding energy.

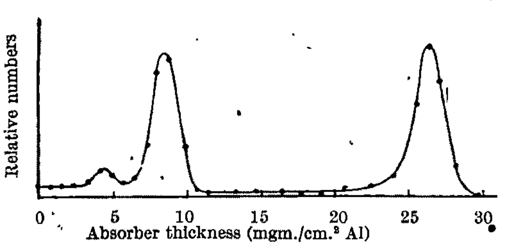

Fig. 1. Spectrum of protons scattered through 110° by magnesium (incident proton energy = 4·73 MeV.)

The spectra of the protons scattered through three different angles by aluminium are shown in Fig. 2, from which it is seen that the first inelastic group has a complex structure. At 90° the peak is nearly resolved into two groups, and can be well explained by the existence of excited states in aluminium-27 respectively 0·80 and 0·97 MeV. above the ground-state. The shape of the peak varies considerably with angle, and in general is too indefinite to admi of such a precise interpretation as that given at 90° though the left-hand component seems fairly wel established at 0·97 ± 0·02 MeV. All that can be said with certainty is that this level is accompanied by at least one other level lying above 0·75 MeV The second inelastic group was able to reach the counter only for scattering angles less than 90°, and corresponds to an excitation energy of 2·15 ± 0·05 MeV. There is little correlation between the excited states of aluminium-27 obtained in this way and existing information[4] on the gamma-rays which follow the beta-decay of magnesium-27.

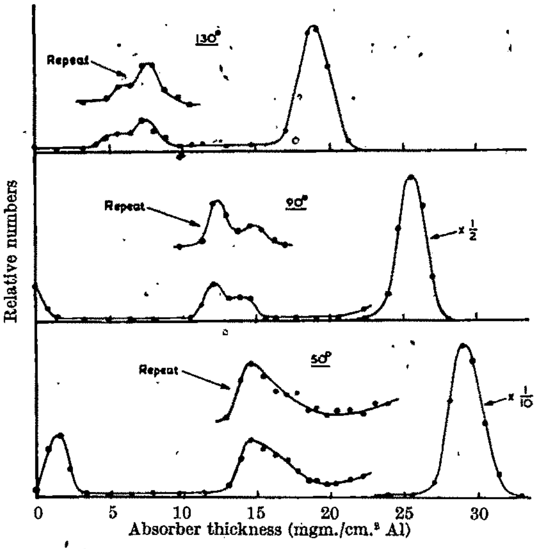

Fig. 2. Spectra of protons scattered by aluminium (incident proton energy = 4·56 MeV.). The vertical scale is not necessarily the same at all angles

The first inelastic group from magnesium is considerably larger than that from aluminium, and has a very different excitation function. The former increases sixfold on raising the incident proton energy from 4·2 to 4·7 MeV., whereas the latter is almost independent of energy in this region. This can be understood in terms of penetration of the potential barrier by the outgoing proton, since, in the case of aluminium, the proton emitted has almost enough energy to pass over the top of the barrier at the lowest bombarding energy used. This suggests that at these bombarding energies the reaction is predominantly a (p, p) process involving formation of a compound nucleus, which is interesting in view of suggestions[5,6] that nuclear excitation might be effected by Coulomb interaction. The total cross-section for excitation of magnesium to the 1·38-MeV. state by 4·73-MeV. protons is about 8×10^{-25} cm.² (assuming it to be associated with magnesium-24), while that for excitation of aluminium to the 0·97-MeV. state by 4·4-MeV. protons is about $1 \cdot 2 \times 10^{-25}$ cm.^{2}. These figures were estimated by an indirect method, and are reliable only to within about 30 per cent.

---

* Now at the Department of Natural Philosophy, University of Edinburgh.

The scattering of protons by beryllium was also investigated briefly, and an inelastic group observed corresponding to an excited state 2·39 ± 0·05 MeV. above the ground-state, in agreement with the results of Davis and Hafner[7]. This state is unstable with regard to neutron emission. No inelastic groups were observed from carbon, oxygen or copper.

I would like to thank Dr. A. E. Kempton and Mr. L. Coates for assistance in the experiments.

MOLECULAR WEIGHT DETERMINATION ON THYMONUCLEIC ACID COMPOUNDS BY DIELECTRIC MEASUREMENTS

By Dr. G. JUNGNER, I. JUNGNER
AND
L.-G. ALLGÉN
Biochemical Department, Karolinska Institutet, Stockholm

Sodium Thymonucleate

THE molecular weight of a thread molecule with a permanent dipole moment such as desoxyribose nucleic acid can be calculated from the anomalous dispersion of the dielectric constant. By the so-called ellipsoid method[1] sodium thymonucleate was shown to have an extremely high dielectric increment, and the molecular weight was found to be very low (only about 16,000). This value, which was obtained only from measurements in 0·1 per cent aqueous solution, has since been found erroneous. In any event, it is quite clear that the dielectric method gives considerably lower values than those obtained by the ultracentrifuge, diffusion or streaming birefringence methods (200,000–1,500,000)[2-4].

In continuing the investigations the ellipsoid method was considerably improved and attained a considerable degree of exactness, and was especially adapted to the unexpectedly high frequencies needed for desoxyribose nucleic acid. Fig. 1 shows examples of some anomalous dispersion curves of the sodium salt of the acid (prepared according to Hammarsten[5]) at different concentrations. The arrows indicate the inflexion points (critical wave-lengths), and the broken curves are the theoretical dispersion curves according to Debye. The smaller graph shows the dielectric increments at different concentrations and at a wave-length of 1,000 metres (0·3 Mc./s.).

The new measurements with 0·1 per cent solution agree well with those previously obtained, except at the highest frequencies, where the earlier results were misleading. Nevertheless, there still occurs a small but constant deviation from the theoretical curve according to Debye (see graph). This deviation can be explained by association, but it indicates that the 'molecular weight' thus obtained is not a true one.

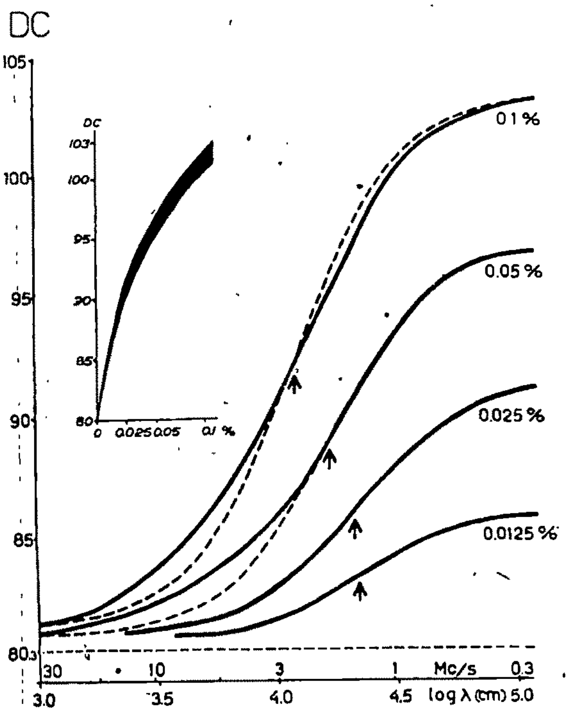

Fig. 1. Anomalous dispersion curves of sodium desoxyribose nucleate at different concentrations. Temperature 20° C. Concentrations in gm. of air-dried substance (moisture content 22·1 per cent) per 100-ml. solution

An attempt to reduce the amount of association by measuring in even more diluted solutions revealed an unexpected effect, namely, that the apparent 'molecular weight' increased with the degree of dilution. This is evident from Fig. 1, which shows that the inflexion point advances towards longer wave-lengths. The reason for this advance is not clear, but we assume that in less dilute solutions a structure is formed (by non-polar association; cf. the smaller graph). In such a structure, the larger aggregates would be impeded in their orientation in the alternating field, and the polarization would be more dependent on smaller and easily movable parts. In very dilute solutions (less than 0·03 per cent) the experimental and theoretical dispersion curves coincide, the critical wave-length is nearly constant, and a dielectrically uniform molecular weight of about 135,000 is obtained.

The high tendency to association led us to doubt whether the new value of about 135,000 was a true molecular weight. It has now also been shown that the 'molecular weight' readily changes, for example, on the addition of small quantities of salts. The effect is completely reversible. It is remarkable, however, that only insignificant additions are needed for the 'molecular weight' to fall, and at a concentration of 0·002 *M* sodium chloride we get approximately 35,000. We have not been able to get lower values. Difficulties due to the method itself prevent measurements in strong salt solutions, and other treatments of desoxyribose nucleic acid (heating, X-ray, etc.) are not reversible. Almost the same value, 33,000, was found by Hammarsten[6] by direct osmotic measurements on sodium thymonucleate in liquid phenol.

The molecule of 35,000 has a quarter of the dipole moment of the 135,000 compound. Thus it is a pure polar association in very dilute aqueous solutions, and the aggregates are built up in exactly the same manner from a dielectric point of view as is assumed for the lower components. Obviously it is necessary to discriminate between *polymerization* and polar (probably end-to-end) *association*. In connexion with aggregates which can so easily be changed that they cannot even exist intact in solutions far below physiological salt concentration, it seems convenient to use the term *association*. *Polymerized* aggregates, on the other hand, will then be decidedly more resistant molecules. The observed value, about 35,000, is then to be regarded as the highest probable molecular weight for the sodium thymonucleate molecule.

The great tendency for desoxyribose nucleic acid to associate seems to be important for the investigation of enzymatic digestion; this should be noted, so that the easy disaggregation may not be mistaken for a depolymerization.

Nucleohistone from Calf Thymus

We have now begun investigations on desoxyribose nucleic acid nucleoproteins, and in the first place nucleohistone. Carter and Hall have made a preparation from calf thymus[7], which has been thoroughly investigated physico-chemically[8,9]. They found the nucleohistone to be monodisperse and to have a molecular weight of about 2,000,000, determined by means of measurements of sedimentation and diffusion. The axial ratio was 35.

We have made five preparations according to Carter and Hall and two others according to Stern[10]. No significant difference in respect of dielectric properties was observed. The chemical composition varied somewhat, and from the results of the analyses a desoxyribose nucleic acid content varying between 42 and 45 per cent was calculated.

Examples of some anomalous dispersion curves of nucleohistone at different concentrations are given in Fig. 2, where the inset graph shows the increments of the dielectric constant at different concentrations and a wave-length of 1,000 metres.

As appears from Fig. 2, the dispersion curves of nucleohistone exhibit the same dependence on concentration as was previously established for sodium thymonucleate (see above). We do not think that this effect can be chiefly due to a change of ion activity or solvation. We assume rather that, as in the case of desoxyribose nucleic acid, it is connected with a structural formation in more concentrated solutions, so that the individual molecule is prevented from orientating itself freely in the electric field.

Calculations of dipole moment and molecular weight were made at the lowest concentrations (less than 0·1 per cent), where the increment rises linearly with the concentration (Fig. 2, inset). The dipole moment calculated according to Debye is then 65×10^{-18} E.S.U. The molecular weight for different preparations varies between 65,000 and 80,000, with a value of about 75,000 as most probable. The content of desoxyribose nucleic acid calculated then corresponds to a molecular weight for that component of about 35,000. This value shows an interesting agreement with our presumed highest conceivable molecular weight for sodium thymonucleate and tha found by Hammarsten[6]. It also indicates that th high molecular weights which will be found fo desoxyribose nucleic acid in dilute aqueous solutions and which are very easily affected by salts, are no true molecular weights.

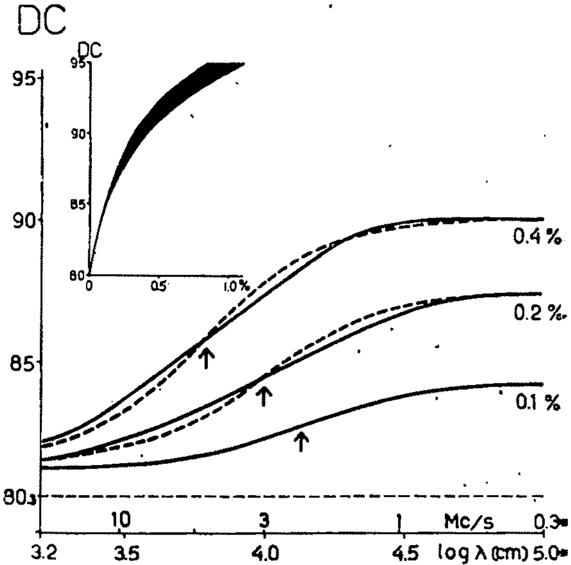

Fig. 2. Anomalous dispersion curves of nucleohistone at different concentrations. Temperature 20° C. Concentrations in gm. of air-dried substance (moisture content 11·7 per cent) per 100-ml. solution

As in the case of desoxyribose nucleic acid, th molecular weight of nucleohistone decreases considerably in salt solutions (about 25 per cent i 0·0004 *M* potassium chloride). The effect is completely reversible, also, by treatment with stronge salt solutions (for example, 1 *M* sodium chloride fo several days). This decrease in molecular weight however, differs from that caused by the influence o salt on desoxyribose nucleic acid in the appearanc of a relatively high content of low molecular parts We think, therefore, that the decrease is due to partial dissociation of the nucleohistone, which doe not necessarily influence the magnitude of th desoxyribose nucleic acid component. Unlike desoxyribose nucleic acid, the molecular weight is no changed in urea solutions.

It has recently been suggested that the nucleohistone prepared according to Carter and Hal probably suffered considerable degradation[11]. Fo this investigation, however, the important point i that the dielectric method gives a considerably lowe value of the molecular weight for this preparation of nucleohistone, as well as for sodium desoxyribos nucleate, than that obtained by other methods.

FULMER RESEARCH INSTITUTE

ANNUAL REPORT FOR 1947–48

THE Fulmer Research Institute, opened in July 1947, is similar in constitution to the Battelle and Mellon Institutes; its first annual report includes a brief description of the main departments —chemistry, physics and engineering, metallurgy, heat treatment—and of their more important equipment. During the eighteen months under review, the staff increased from forty-five to sixty-five, and sixteen workers with university degrees or equivalent qualifications and sponsors' nominees are now engaged in the laboratories under the director of research, Mr. E. A. C. Liddiard. The scientific staff is headed by Dr. P. Gross and Dr. A. H. Sully.

Only a general account of work in progress is given in the report. The team working under Dr. Gross has been mainly concerned with further studies of the reaction between metallic aluminium and aluminium trichloride vapour at 900–1,000° C. and at a few mm. of mercury pressure to give aluminium monochloride, AlCl. The vapour thus formed decomposes again on cooling into the trichloride and aluminium, and the reaction is expected to provide the basis of a new process for extracting and refining aluminium by 'catalytic distillation'. A semi-technical plant is under construction, and the process may possibly permit the extraction of aluminium by carbo-thermic reduction of low-grade ores. Experiments on the possibility of refining other metals by a similar technique indicate that silicon, boron and nickel can be distilled in this way.

An investigation is also in hand to develop materials with improved properties at high temperatures, particularly chromium-base alloys, and for this purpose a high-frequency generator and furnace have been constructed. Machines have also been designed and constructed in the laboratory workshops for measuring the creep of alloys in tension and in compression up to 1,000° C., and have given results of surprising accuracy. Pure alumina crucibles and other shapes have been made by slip casting and firing in the laboratories, and in view of the good service obtained, research has been extended to the refractories field. The recrystallization of refractory oxides is being studied by X-ray diffraction, and a comprehensive investigation is being made of the mechanism of precipitation in high-purity aluminium–copper alloys, with particular reference to the effects of third elements on lattice spacing. The constitution of aluminium–tin alloys has been studied with particular reference to the solid solubility of tin in aluminium and to the effects of tin on mechanical and physical properties, casting characteristics and hardening by precipitation. The properties of fluxes used in remelting aluminium cuttings and turnings are being investigated with the object of increasing their efficiency in preventing oxidation and decreasing metal losses, and a comprehensive investigation on the corrosion of aluminium alloys used in buildings is in progress. The causes and prevention of blisters and similar defects in plated aluminium articles are being studied, and various problems associated with the development of high-speed knitting machines have been solved.

Some 138 inquiries, some outside the field of light alloys or metallurgy, were dealt with in the period. A list of published notes and papers is appended, together with the names of sponsors and a list of staff.

GLASSHOUSE RESEARCH

THE annual report of the Experimental and Research Station at Cheshunt always sets forth a crop of useful results; but the latest one, which is for 1947 (the Station, Turner's Hill, Cheshunt, Herts; 1948), provides the answers to many questions on glasshouse culture. J. Littlewood and O. Owen publish the results of extensive experiments on the relation between the amounts of plant nutrients in the soil and those in the plant, with particular reference to methods of soil extraction used in advisory analyses. They conclude that extractions for potash with $N/2$ acetic acid, and for phosphoric acid with distilled water, give the most practically useful results. This is important; but even more urgent is their insistence on the determination of total nitrogen for advisory purposes, and it is impossible not to agree most strongly with this conclusion. O. Owen and G. W. Winsor have also studied in detail the question of nitrification in glasshouse soils. Farmyard manure is now scarce, and O. Owen has a useful paper on the use of sodium alginate as a substitute for it in tomato composts. The preliminary trials show that it is quite satisfactory.

The tomato moth, *Diataraxia oleracea*, causes serious injury in some commercial glasshouses. A very detailed paper by E. R. Speyer and W. J. Parr assesses its economic importance, describes the various stages of its life-history, and reviews methods for control. The pest was responsible for an annual loss of crop worth £30,000 in the Lea Valley in 1918, was later controlled to negligible proportions as a result of Lloyd's advice to spray with lead arsenate, and again assumed serious proportions following war-time changes in cropping. D.D.T. can now be used successfully against this insect; but the paper also discusses the value of other substances and methods for control. The uses of insecticides for other particular purposes are described by W. H. Read. Azobenzene fumigant and petroleum emulsions provide about equal control of red spider, and the use of hexaethyltetraphosphate is promising.

Didymella stem rot is a serious trouble. It is shown by P. H. Williams to be more severe when nitrogen is in excess in the soil, and its spores can withstand freezing temperatures. W. H. Read has tried treatment with ethyl mercury phosphate; but this does not, as yet, provide a hopeful means of control. R. Howles shows, *inter alia*, that tomato plants kept turgid by the provision of adequate water had less severe virus symptoms than when less water is given. The control of soil pathogens by means of antibiotic substances is a fascinating possibility, and E. Grossbard has found that *Penicillium patulum* will produce a growth-inhibiting substance when cultured on sugar-beet pulp or straw with glucose. The substance is antibiotic to several organisms, including *Bacillus carotovorus*, *B. phytophthorum*, *Phytophthora parasitica* and *P. cryptogea*.

More general investigations, under the control of Dr. W. F. Bewley, director of the Station, include a comparison of sterilizing by steam and by formaldehyde, the use of straw between rows, the effect of withholding lime and phosphate, the usual variety trials, and experiments on watering. These have all yielded results suitable for immediate practical application, and represent the delivery of the digested work of the Station to the industry it serves so well.

J. GRAINGER

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, May 31

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Prof. A. V. Hill, F.R.S.: "Muscular Contraction".* (Further Lectures on June 7 and June 14.)

INSTITUT FRANÇAIS (at Queensberry Way, London, S.W.7), at 6 p.m.—M. Paul Couderc: "Astronomie nouvelle".*

Wednesday, June 1

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Edwin H. Land: "Optical, Polarisers".

Thursday, June 2

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Dr. J. S. Bach: "Some Aspects of Nitrogen Metabolism in the Mammal".* (Further Lectures on June 9, 16 and 23.)

PHYSICAL SOCIETY (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Dr. E. H. Land: "A Colour Translating Ultra-Violet Microscope" (Twenty-sixth Duddell Lecture). (Members of the Optical Group are invited.)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT PHYSICIST IN THE PHYSICS DEPARTMENT—The Secretary, Westminster Hospital, St. John's Gardens, London, S.W.1 (June 3).

LECTURER IN MATHEMATICS at the Constantine Technical College—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (June 4).

LECTURER IN PHYSICS—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford (June 4).

LECTURER IN BIOLOGY to teach botany and zoology up to Intermediate B.Sc. standard—The Principal, Aston Technical College, Whitehead Road, Birmingham 6 (June 4).

SENIOR LECTURER IN GEOGRAPHY (up to Final Degree standard with special reference to Economic and Political Geography) at the Brighton Technical College—The Education Officer, 54 Old Steine, Brighton (June 4).

LECTURERS IN SCIENCE, and a LECTURER IN MATHEMATICS, at the Royal Military Academy, Sandhurst—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 2564 (June 9).

SENIOR ASSISTANT IN MATHEMATICS at the Leeds College of Technology—The Director of Education, Education Department, Leeds 1 (June 11).

EDITOR of the "British Pharmaceutical Codex", "Extra Pharmacopoeia" and other scientific publications—The Secretary and Registrar, Pharmaceutical Society of Great Britain, 17 Bloomsbury Square, London, W.C.1 (June 11).

HISTOLOGIST to collaborate in researches on endocrinology of lactation and reproduction and other research projects involving histological studies—The Secretary, National Institute for Research in Dairying, Shinfield, Reading (June 11).

SENIOR SCIENTIFIC OFFICERS, SCIENTIFIC OFFICERS, EXPERIMENTAL OFFICERS and ASSISTANT EXPERIMENTAL OFFICERS, for work on the physics of metals in Ministry of Supply Research and Development Establishments in London and S. England—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1190/48A (June 11).

PROFESSOR OF GEOLOGY, and LECTURERS IN GEOGRAPHY, BOTANY, MARINE ZOOLOGY, ORGANIC CHEMISTRY, and GEOLOGY, in the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 13).

CHAIR OF APPLIED MATHEMATICS, THE CHAIR OF EDUCATION, THE CHAIR OF HISTORY, a LECTURER IN PHYSICS, and a LECTURER IN SOCIAL STUDIES, at Raffles College (University of Malaya), Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 13).

DEMONSTRATOR OF BIOLOGY—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (June 15).

LECTURER (Grade II) IN APPLIED MATHEMATICS—The Secretary and Registrar, The University, Bristol (June 17).

SENIOR LECTURER or LECTURER, and an ASSISTANT LECTURER, IN THEORETICAL PHYSICS—The Registrar, The University, Manchester 13 (June 17).

PHYSICIST to the Regional Radium Institute—The Secretary, Bradford 'A' Group Hospitals Management Committee, Royal Infirmary, Bradford (June 18).

ASSISTANT MASTERS (with a degree or equivalent qualification in Mathematics, Physics, Mechanical or Electrical Engineering) in H.M. Dockyard Schools at Portsmouth, Devonport, Chatham, Sheerness and Rosyth—The Director (P.A.), Education Department, Admiralty, London, S.W.1 (June 18).

SEAGOING OBSERVERS (with a good general science background up to at least Intermediate B.Sc. standard in chemistry, physics and one other subject, preferably biology) on distant-water trawlers—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.333/49A (June 20).

DIRECTOR of the Laboratory Animals Bureau and SECRETARY of the Council's Advisory Committee on the Supply of Laboratory Animals—The Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1 (June 20).

LECTURER IN PURE MATHEMATICS—The Registrar, King's Colleg Strand, London, W.C.2 (June 24).

ASSISTANT LECTURERS (2) IN THE DEPARTMENT OF ORGANIC CHEMISTRY—The Registrar, The University, Liverpool (June 25).

NATURALIST at the Dove Marine Laboratory—The Registra King's College, Newcastle-upon-Tyne (June 25).

ASSISTANT KEEPER (Biology, with special knowledge of botany and an ASSISTANT KEEPER (Geology, with special knowledge palæontology)—The Director, Museum and Art Gallery, Leicest (June 25).

LECTURER or ASSISTANT LECTURER IN GEOGRAPHY—The Registra The University, Leeds 2 (June 25).

PLANT PHYSIOLOGIST and a PLANT BREEDER (Junior Professiona Officers grade) in the Tobacco Division, Department of Agricultur Southern Rhodesia—The Secretary to the High Commissioner f Southern Rhodesia, 429 Strand, London, W.C.2 (June 30).

KEEPER OF THE DEPARTMENT OF GEOLOGY, a KEEPER OF TH DEPARTMENT OF ETHNOLOGY, and an ASSISTANT KEEPER IN ARCHÆOLOGY AND ETHNOLOGY, in the Liverpool Museums Department—The Town Clerk, Municipal Buildings, Liverpool 2 (June 30).

PRINCIPAL SCIENTIFIC OFFICER under the Ministry of Supply fo technical administration and organisation of research work in physics metallurgy carried out in academic, industrial and Government laboratories in connexion with aircraft metals and alloys—The Minist of Labour and National Service, Technical and Scientific Register (K York House, Kingsway, London, W.C.2, quoting F.332/49A (June 30

ASSISTANT KEEPER to be responsible for the Zoological Collectio in the Manchester Museum—The Registrar, The University, Manchester 13 (July 1).

PRINCIPAL SCIENTIFIC OFFICER for supervision of all aspects, research and development in Helicopters from project stage to completion of tests on experimental types, under the Ministry of Supply—The Ministry of Labour and National Service, Technical and Scientifi Register (K), York House, Kingsway, London, W.C.2, quotin C.303/49A (July 2).

PROFESSOR OF THEORETICAL PHYSICS—The Registrar, India Association for the Cultivation of Science, Calcutta 12, India (July 15

LECTURER IN MATHEMATICS, a LECTURER IN METALLURGY, and LECTURER IN CHARGE OF GENERAL AND ADULT STUDIES, at the Wolverhampton and Staffordshire Technical College—The Clerk to the Join Education Committee, Education Offices, North Street, Wolverhampton.

SENIOR INSPECTOR, and INSPECTORS (2), under the Seed Productio Committee—The Secretary, National Institute of Agricultural Botany Huntingdon Road, Cambridge.

LECTURERS or ASSISTANT LECTURERS (2) IN CIVIL or MECHANICA ENGINEERING, and a LECTURER or ASSISTANT LECTURER I METALLURGY—The Registrar, The University, Nottingham.

CARTOGRAPHERS in the War Department Map Production Establishment—The Survey Production Centre, R.E., 309 Elveden Road London, N.W.10.

LECTURERS (2) IN THE DEPARTMENT OF MATHEMATICS—The Directo of Studies, Royal Naval College, Greenwich, London, S.E.10.

LECTURER IN STATISTICS—The Registrar, The University, Reading

METALLURGIST in the laboratory at Derby—The Scientific Researc Manager, Railway Executive (London Midland Region), Eusto Station, London, N.W.1.

LECTURER IN PHYSICS to Special B.Sc. standard—The Principal West Ham Municipal College, Romford Road, Stratford, London E.15.

LECTURER IN THE DEPARTMENT OF METALLURGY, and a GEOGRAPH MASTER, at the County Technical College, Wednesbury—The Directo of Education, County Education Offices, Stafford.

PHYSICAL CHEMIST with some research experience—The Secretary British Rayon Research Association, 58 Whitworth Street, Manchester

PROFESSOR OF EXPERIMENTAL PHYSICS—The Registrar, Universit of Manitoba, Winnipeg, Canada.

RESEARCH ASSISTANT (graduate in Physiology or Zoology) to joi group investigating biological effects of radioactive substances—Dr. Janet Vaughan, Department of Pharmacology, Oxford.

MUSEUM TECHNICAL INSTRUCTOR by the Government of Nigeria—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quotin M.N.22382/3E.

LABORATORY ASSISTANT—The Headmaster, Hackney Downs School Downs Park Road, London. E.5.

HISTOLOGICAL TECHNICIAN IN THE DEPARTMENT OF ANATOMY—The Secretary, St. Mary's Hospital Medical School, Paddington London, W.2.

LECTURER IN BIOLOGY—The Principal, Royal Technical College, Salford 5.

MECHANICAL ENGINEER for experimental investigation of stresses in motor vehicle components, and an ELECTRICAL ENGINEER o PHYSICIST for research and development work on the application o electronic methods to mechanical engineering problems—The Director Motor Industry Research Association, Great West Road, Brentford Middx.

RESEARCH OFFICERS (2) for fundamental research in chemica problems connected with the manufacture of gelatine and glue—The Director, British Gelatine and Glue Research Association, Sardinia House, 52 Lincoln's Inn Fields, London, W.C.2.

ASSISTANT or ASSOCIATE PROFESSOR OF ORGANIC CHEMISTRY—The Secretary, Department of Chemistry, University of Britis Columbia, Vancouver, Canada,

HEAD OF THE DEPARTMENT OF PHYSIOLOGY—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3.

TEA RESEARCH OFFICER in Nyasaland—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

TIMBER INVESTIGATIONS OFFICER for the Forestry Department, Government of Sierra Leone—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.22155/3E.

HONOURS GRADUATE, with first-class basic training in Chemistry or Biochemistry (or Chemical Engineering or Agricultural Chemistry), for training as a Fish Processing Expert—The Under-Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1.

NATIONAL PARKS IN BRITAIN

WHILE the National Parks Bill received an unopposed second reading in the House of Commons, the course of the debate indicated that some modification might be expected at the committee stage. Dr. Hugh Dalton, indeed, on April 1 went so far as to suggest that members who had ideas on the functions of the commission or the planning authority or any other matters that had been discussed might possibly find their ideas accepted, perhaps in modified form, during the committee stage. There may well be a brisk response to this encouraging, if unusual, pronouncement, though it may be a matter of opinion whether the two most important points on which criticism fastened—the composition of the park planning authorities and the powers of the National Parks Commission—are really committee points as Mr. Dalton suggested.

The Bill makes the National Parks Commission responsible for the preservation and enhancement of natural beauty in England and Wales, and particularly in the areas to be designated under the Act as national parks or as areas of outstanding natural beauty, and for encouraging the provision or improvement of facilities for enjoying the national parks and the opportunities the parks afford for open-air recreation and the study of Nature. Nevertheless, the Commission is to be wholly advisory, and there appears to be no provision for making its advice effective or even to ensure that local authorities act on its recommendations; further, as Sir Arthur Salter pointed out, the Commission is to be advisory in matters upon which it is most unlikely that its advice would prevail against contrary interests.

The full significance of this weakness is o[illegible] apparent when it is realized that the administra[illegible]on of the national parks and execution of the proposals of the National Parks Commission is to be entrusted to the local authorities, either to the planning board of a single authority, or to a joint board where the area of the proposed park falls into several counties. If the Minister decides to dispense with a joint board, the local planning authorities concerned must have a separate committee to deal with any land in their area which is within the boundaries of the park. At least one quarter of the members of the joint boards, advisory committees or special committees appointed for the purpose must be appointed from persons nominated by the Minister after consultation with the Commission. The preparation of development plans for an area including any part of a national park is to be the responsibility of the local planning authorities, who are to be allowed one year after a national park order made by the Commission comes into effect to formulate proposals, which they must discuss with the National Parks Commission.

Such procedure does not warrant optimism that national parks will come into being at an early date. Moreover, the urgency of the problem arises largely, if not primarily, from the action of Government departments which, as was stressed on all sides in the debate, neither the National Parks Commission nor the local authorities will have powers to resist. This, however, as the Hobhouse Committee insisted, is the major threat to national parks in Britain, and its reality has been emphasized by what has been happening in regard to Dartmoor and other areas while the Bill has been under debate. There is no confidence, indeed, in the ability of the Minister of Town and Country Planning to resist such pressure. Mr. Dalton's statement in the debate that something like what is proposed in the Hobhouse Report, namely, the submission of matters in dispute to a permanent group of Ministers, is already the practice, might have been better received if the evidence were more convincing that Service departments are not allowed to be judges in their own cause.

In view of Mr. Dalton's statement that an inter-departmental committee of senior ministers is already operative, it is difficult to understand the reluctance of the Government to adopt openly a recommendation which would go far to restore confidence in the genuineness of its support for national parks. As it is, Mr. Silkin, in addressing a meeting of the Ramblers' Association on April 10, still burked the plain fact that if the conservation of Nature and of natural beauty is to mean anything, at some point a National Parks Commission or an inter-departmental committee of Ministers must have the right to over-rule a particular ministry. The Government itself apparently refuses to recognize the implications of the conflicting demands of so many kinds, all based on genuine national interest, for our limited resources of land; and the failure to co-ordinate, in particular, the Services demands for training areas exacerbates a public opinion which, although it fully recognizes the vital importance of setting aside a proper proportion of land for that purpose, rightly declines to admit that each particular demand can be discussed [illegible] isolation or without regard to other national interests.

The whole point of the argument for national parks is that there are some areas in which the claims of amenity and of natural beauty must come first; even such a vital interest as defence cannot come first all the time, or there will be nothing left to defend. It could be wished that, in introducing the Bill, Mr. Silkin had shown more clearly that he recognizes amenity or natural beauty as a national need and a public interest, and that its claims have to be weighed along with other public interests—the need for food, for water, for electric power, minerals, military training and the rest. In conservation areas its claims must be given more than the usual weight: in national parks they must preponderate and only be over-ruled in some grave and dire emergency.

Some encouragement may be drawn here, however, from Mr. Silkin's reference to a wider function of the Commission which goes beyond the recommendations of the Hobhouse Committee. The Commission is to be responsible generally for directing attention to any question affecting natural beauty in any part of England and Wales, and will also be responsible for selecting the other areas of natural beauty to which special powers are to apply. These areas will normally be smaller in extent than the national parks and, for that, or some other reason, therefore unsuitable for designation as national parks. That function can be adequately discharged unless there is full harmo of purpose between the Commission and the plann committees to whom the executive powers are to entrusted. If the parks are administered by jo boards or, in the single-county areas, by the spe committees to which Mr. Silkin referred, it is impossible that, in the hands of men and women w care deeply for the purposes the Bill purports serve, we may see real national parks and merely local authority parks. What should remembered is that the proposed composition of joint planning boards or special committees place heavy strain on the loyalties of the members appoin by the local authorities—a strain that could reaso ably be argued as invidious.

While that contention finds some support in wh for example, has been manifested already in lo council elections in the Lake District, it should still remembered that the main threat to the preservati of natural beauty comes from public authoriti whether they are local or central. The National Pa Bill does, indeed, provide the means for the claims natural beauty to be advanced as a public intere Whether representations will be effective agai claims of other public interests, both local a central, appears to depend less on the organisati established by the Bill than on our ability administer its provisions with the determination a imagination which will realize the capacities for go which are undoubtedly inherent in the Bill.

Nowhere is this more apparent than in regard the further duty to be laid on the Commission selecting the long-distance footpaths. That duty complementary to the duty placed on the coun councils of conducting within three years a surv of all the public paths in their area, and preparing draft map showing existing footpaths or bridle-wa Some county councils, such as those of Essex, Ham shire and West Sussex, have already taken a ke interest in footpaths and done much of the surveyi and signposting required. Moreover, their work h already demonstrated how far success in this fie depends on co-operation with the urban distric parish councils, private landowners and volunta organisations such as the Ramblers' Association a the Commons, Open Spaces and Footpaths P servation Society.

The progress which some counties are already a to report in this field is one reason for hope, especial as it has indicated practical examples of co-operati between public authorities and voluntary organis tions, and some of the financial difficulties in rega to maintenance which hitherto have been responsi for reluctance to implement long-distance footpat such as the Pilgrims' Way, the coastal paths or t proposed Thames riverside walk from Teddington Cricklade. The National Parks Commission's selecti in this field must clearly be accompanied by reco mendations in regard to the cost of maintenance the Pennine Way and similar proposals are materialize. The financial clauses of the Bill provi for national contributions for that purpose, as w as to the Nature Conservancy.

So far as Nature conservation is concerned, the Bill supplements the powers conferred by royal charter on the Nature Conservancy and gives local authorities the necessary powers to set up local Nature reserves. Powers to acquire land compulsorily are conferred on the Nature Conservancy where it is expedient in the national interest that the land should be managed as a Nature reserve, or where there has been a breach of any agreement prejudicial to its management. Nevertheless, it is clearly intended that here also the normal method of acquisition or management shall be by voluntary agreement; and the full purpose of Nature conservancy as defined in the Bill—the provision of special opportunities for the study of, and research into, matters relating to the fauna and flora of Great Britain and the physical conditions in which they live, and for the study of geological and physiographical features of special interest, as well as the preservation of flora, fauna or such geological and physiographical features—will only be achieved with the full understanding and co-operation of all those concerned, whether private landowners or occupiers, local authorities, or Government departments.

These parts of the Bill are all linked up naturally with the wider and more controversial question of public access to the open countryside. Given that the Government is in earnest in its determination to stop the piecemeal encroachment of Government departments and make the establishment of national parks really effective, whether the purpose of national parks is achieved depends on public understanding and co-operation. There must be no confusion in the public mind between the different purposes of national parks and Nature reserves; the reasons for the different conditions of access must be clearly understood. Moreover, as was repeatedly emphasized in the debate, national parks in Britain, unlike those in other parts of the world, cannot be divorced from ordinary rural life. In them farming, rural industry and afforestation must function as nearly to normal as possible, and accordingly rights-of-way and public access to open country involve responsibilities and duties. The building up of a higher code of conduct on the part of those who enjoy the new opportunities, and the observance of that code less through penal enactment than under the compulsion of a public opinion that fully understands the reasons for the code, is a far surer way of securing the essential *rapprochement* between townsman and countryman.

This lies at the root of the whole matter; it is a disturbing feature in the life of Britain to-day that estrangement between townsman and countryman so readily arises. Numerous factors contribute to that discord; a significant recent example was the failure of farmers in Derbyshire to join with the Council for the Preservation of Rural England and the Ramblers' Association in opposing the extension of the Hope Valley cement works, although the taking of good farmland for clay-pits was the most vulnerable part of the scheme. The reception of Mr. Silkin's Bill in the House of Commons, however, testified to the existence of a large amount of goodwill and understanding on all sides. Strongly as the claims of agriculture were pressed, they were not advanced to the exclusion of other interests, and the whole spirit of the debate encouraged the hope that a satisfactory compromise between all interests will be found provided the Government deals resolutely with the tendency of Government departments to advance piecemeal proposals and attempt settlements which ignore other interests.

If the goodwill shown in the debate continues during the committee stage, the Act going to the Statute Book may satisfy most of the aspirations so widely entertained since Lord Addison's Committee first explored the question of national parks in 1930. Whatever the form of the Act, much will inevitably depend on Government action, public understanding and the establishment of a fresh harmony between townsman and countryman. Nothing could contribute more to the creation of the right atmosphere than a clear lead from the Government on the vexed question of land for the Services. Given this, and the imaginative and energetic exercise by the National Parks Commission of its functions of publicity and the provision of information services, there may be created a public understanding which will prevent the abuse of rights-of-way and access; further, by easing, if not removing, the clash of loyalties which the entrusting of the administration of the parks to local authorities at present involves, the Act will give Britain a system of parks and reserves which are, in fact and in spirit as well as in conception, truly national.

ORIGIN OF THE UNIVERSE

L'Hypothèse de l'atome primitif
Essai de cosmogonie. Par Prof. Georges Lemaître. (Les problèmes de la philosophie des sciences.) Pp. 203. (Neuchâtel: Éditions du Griffon; London: H. K. Lewis and Co., Ltd., 1946.) 8 francs; 10*s*.

PROF. GEORGES LEMAITRE is the eminent relativistic cosmologist (at one time a pupil of Eddington) who in 1927 independently discovered a solution of Einstein's gravitational equations which made the curvature of space depend on the time and so gave an explanation of the expansion of the universe of nebulæ. Actually he was anticipated by A. Friedmann, who had in 1922 and 1924 discovered forms of the fundamental metric of the homogeneous universe which involved the time; but Lemaître himself has always given the credit for the discovery to Friedmann, even to the extent of barely doing justice to himself. Lemaître's paper, which was published in Belgium, was overlooked by Eddington at the time; but it was due to Eddington that the Royal Astronomical Society published a translation of Lemaître's paper in 1931. In the present volume, Lemaître reproduces *seriatim* five addresses delivered by him on various occasions between 1929 and 1945, the title of the last of them giving its name to the present volume. There is also an inspiring preface by Ferdinand Gonseth, the distinguished professor of philosophy at Zurich. Though there are a few mathematical formulæ in the text, the style is that of semi-popular exposition, and detailed mathematical explanations are confined to an appendix.

The point of view of the author is that of orthodox relativity, and as a persuasive outline of that point of view in relation to world structure the addresses could scarcely be bettered. His account of 'curved space', illustrated by means of a Euclidean map, almost over-reaches itself; for why (the reader is inevitably led to ask), if the map is so successful, does the author consider the curved space as reality and reject the Euclidean equivalent as a mere map? He claims to prove that the number of stars in the universe must be finite, but the proof is question-begging. He believes firmly in the existence of the so-called 'cosmological constant', and believes, too, that it must be positive. But he admits, what is sometimes forgotten, that Einstein's relativistic theory of gravitation teaches us nothing about the signs or magnitudes of the two 'constants' of gravitation, and it is therefore surprising that he should be satisfied that a theory which goes so little into the fundamental nature of gravitation should be capable of explaining the origin and evolution of the universe.

This complacency, and consequent failure to see the need for a deeper theory of gravitation, run right through the volume. For example, his mathematical appendix opens with the unsatisfying statement that *proper time* is "the time for which identical experiences successively repeated have the same duration", when, as every philosopher knows, there is no recipe for saying what is meant by 'successive identical experiences', since you cannot put the fleeting minute side by side with a previous minute. Kinematic relativity, on the other hand, gives a rigorous definition of congruent clocks at a distance in any kind of relative motion, and it is because it really begins with fundamentals that it is able to refine on orthodox relativity to the extent of showing that in different dynamical contexts different scales of time are taken to be uniform.

The hypothesis of the primitive atom, a super-radioactive nucleus, as the origin of the universe and the source of nebulæ, clusters of nebulæ and cosmic rays, may seem at first sight, to the hard-boiled physicist, a mere piece of scientific romancing, but it is most attractively expounded by Lemaître. He admits that he may be pushing his description of the detailed sequence of events too far: an initial period of expansion; then a slowing-down as the universe passes through a near-equilibrium state corresponding to an Einstein universe; lastly, a further period of expansion, with the nebular clusters at a mean density of 10^{-27} gm. cm.$^{-3}$ as the fragments of an Einstein configuration of equilibrium between Newtonian inverse-square attraction and cosmological repulsion varying as the distance, and with cosmic rays as the fossil relics of the initial super-radioactivity. But it is becoming increasingly certain that any theory of evolution must envisage conditions near the natural zero of time drastically different from those now ruling.

Kinematic relativity agrees with the essence of Lemaître's hypothesis in tracing the state of the universe backwards to a point-singularity, before which there was neither space nor time nor becoming; and J. B. S. Haldane's related speculations at least show how some of the most vigorous minds of to-day are reacting in the same sense. The one thing that kinematic relativity insists on with regard to this singularity is that no propositions can be asserted about the state of affairs at that epoch; it is transcendent, as becomes the event of the creation of the universe. Lemaître's identification of this singularity with an actual super-radioactive atom seems to m too definite a thesis to maintain; indeed, to definite to have a chance of being true. Bu physicists and astronomers who are sceptical abou the value of theories of world evolution will at leas find food for thought and further reflexion i Lemaître's volume.

E. A. Milne

SCIENCE AND HUMANISM

Gods and Men

A Testimony of Science and Religion. By Sir Richard Gregory. Pp. viii + 214 + 8 plates. (London Stuart and Richards, 1949.) 12*s*. 6*d*. net.

Sir Richard Gregory and I have grown old together; his memory and mine go back to the days when religion and science were in open conflict and when Huxley was assuring his hearers that the more the methods of science took hold of mankind the less would be its belief in supernatural powers and influences. Sir Richard was a pupil of Huxley; no one is better qualified than he to bear testimony as to how the conflict has gone in the last sixty years For forty-five of these years he was editor of *Nature* —a position which entails an intimate knowledge of all branches of science and of the bearing of scientific knowledge on every form of human activity In "Gods and Men" he states, objectively and dispassionately, the relationship which does exist, as well as the relationship which ought to exist, between science and religion. He does not share my fear that the present truce is an uneasy one; the opposite—he is of opinion that the conflict is a thing of the past and that the future must see an active collaboration of science and religion if mankind is to prosper.

The following paragraph illustrates the manner in which Sir Richard states his case for the reconciliation of science and religion:

"In recent years it has become increasingly evident that this [the doctrine of immortality] and other traditional beliefs cannot have a place in progressive thought apart from scientific knowledge and historical evidence. Responsible leaders in the Church of England to-day represent a new and enlightened attitude towards the so-called 'heresies' of scientific thinkers, which convulsed English society in the nineteenth century from the days of Dean Buckland down to the pitched battles which took place on the scientific positions of Charles Darwin, T. H. Huxley John Tyndall and their successors" (p. 142).

I do not think that this instance can be accepted as evidence that science is causing religion to lose its hold on the great public. Indeed, Sir Richard recognizes this and admits that *most* church-goers regard "the acceptance of such views as a capitulation to the forces of modernism and scientific materialism" As evidence of the hold that religion has on the public of England I would cite the fact that the most worldly minded of newspapers adorn their opening page with a biblical text and that at all times the B.B.C. is offering a 'word in season'! Science in nowise hinders the drift of our most eminent literary men from seeking succour in the Roman Catholic Church.

Sir Richard is a devout humanist; for him humanism is a religion. Humanism he defines as "the integration of all human influences which promote the development of the human race, whether in ncludes the teaching of a particular religion or not. Whatever principles or practices raise man out of his nimal ancestry and add to his status among living reatures can rightly be termed humanistic." Humanists believe that human affairs go forward without interference from supernatural powers. However passionately an ideal for the betterment of nankind is held, unless the overlordship of a Divine ower is recognized, that ideal will not be accepted by he orthodox as worthy of the name of religion. Critics might rightly urge that it is humanism, not eligion as usually understood, which Sir Richard lesires to reconcile with science. Humanism and cience need no reconciliation.

Throughout the latter half of "Gods and Men" ir Richard directs his argument to support a high deal which he and his life-long friend, the late Mr. H. G. Wells, held in common—the ideal of all nankind being welded into a human brotherhood nd becoming members of a single world State. The essence of all great religious systems," he claims (p. 130), "is belief in the attainment of high leals by devotion of service to them." If we accept his claim, as men of science are likely to do, then Gods and Men" may be described as a religious ook and its author as an intensely religious man. One bar to the realization of this ideal is the irreconcilability of the doctrinal elements in world eligions. But if the doctrinal element is left out of consideration, there remains in all of them a common element—the ethical or moral element. It is out of this common or ethical element that Sir Richard sees the possibility of constructing a "world religion". "In this composite but practical creed," he maintains (p. 131), "it is permissible to consider the movements oward world fellowship as representing a further and higher stage in the development of religious belief, in which the theological differences which ntagonize will be forgotten in the pursuit of a common and universal moral purpose."

Huxley believed that as the kingdom of science extended its rule the reign of the supernatural would ose its hold on the minds of mankind. Gregory and have seen science become an ever more powerful factor in the life of man; but religion has not lost s hold on the human heart. That is because religion vas born in the human heart, not in the human head. It answers certain basal needs of the 'heart', hat is, of human nature. "The social and cultural onditions change," it is noted (p. 157), "but human ature remains in most respects unaltered". That, think, is why religion holds its own in spite of the great advance of science. Perhaps it is just the unmalleability of those mental elements which go to the make-up of human nature that now stands as the hief obstacle to the realization of Sir Richard regory's ideal—a universal brotherhood.

In writing this book the author has submitted himself to the rigorous discipline of the scientific method; even when dealing with those matters of doctrine, to the handling of which religious minds are most sensitive, his methods of statement remain purely objective. He is critical but never aggressive. Yet his application of the method of science to religious roblems seems to have given offence in some quarters. In a literary journal where orthodoxy is upheld, a ritic has bluntly stated that "Gods and Men" is a ook which should never have been published. The ish to suppress such a book is evidence that the onflict between science and religion is not yet over.

ARTHUR KEITH

ORIGIN AND GROWTH OF THE ROYAL SOCIETY

Scientists and Amateurs

A History of the Royal Society. By Dorothy Stimson. Pp. xiii + 270 + 20 plates. (London: Sigma Books, Ltd., 1949.) 15*s.* net.

IN the present century we have grown so accustomed to the supremacy of the Royal Society in all matters scientific that it is difficult to realize it has not always possessed its high reputation. Such is its authority and its high seriousness to-day that it is hard to believe there have been times when it has been scoffed at and derided for the triviality of its pursuits. Yet this is the case. The Society derives its reputation from the scientific eminence of its members; yet there have been long periods in its history when a majority of those elected to its fellowship have not been men of science at all, when election has been a mark of social rather than of scientific distinction.

Other histories of the Royal Society have been published, written, as histories of institutions often are, by those intimately connected with its administration and drawing on personal knowledge of the various aspects of its affairs. The work under notice is of a different character. It is the outcome of a study by Miss Stimson of seventeenth-century science in England, and as an essential part of that theme, an inquiry into the origins and growth of the Royal Society. The result is a book for the general reader, primarily the American reader, written in a detached and objective manner, and setting the history of the Society against the intellectual, social and historic background of the seventeenth and later centuries. It is an interesting, indeed an absorbing story, and the treatment is original and refreshing.

The title is, I think, a little misleading. It draws a distinction between the professional men of science and those amateurs, the *virtuosi*, who played such a large part in the foundation and the early activities of the Society; but there is a sense in which all true scientific men have remained amateurs, and there are among us, even to-day, some few individuals whose devotion to science is a thing apart from their bread-and-butter interests. In this regimented and socialized age, when we are all classified and labelled, it is well to remember that there are still some who have made great contributions to knowledge, and yet cannot readily answer the question, "What is your profession or occupation?" They have preserved that independence and integrity of mind from which must always spring the advances of the human intellect.

Miss Stimson passes in brief survey the writings of Francis Bacon, the ideas of such men as Comenius and Hartlib, of John Evelyn and Robert Boyle, of Sir Thomas Gresham and his College in the City of London, of the whole movement towards the new learning based on experiment and observation which culminated in the foundation of the Royal Society by Charles II. The meetings of the 'Invisible College' in London and Oxford preceded this royal recognition and encouragement. One of Charles's principal scientific interests was the progress of astronomy as an aid to navigation, and there grew out of this, on the establishment of the Royal Observatory and the setting up of John Flamsteed as the first Astronomer Royal, the association of the Royal Society and the Royal Observatory which has lasted ever since.

Charles's great Navy secretary, Samuel Pepys, was one of the early presidents of the Society. The Society's connexion with the Royal Observatory is closely paralleled in more recent years by its responsibilities for another great national institution, the National Physical Laboratory. From the earliest years the Society has been consulted by the Government in scientific matters, and the advice it has thus been able to give constitutes one of its most valuable public services.

It is well known that King Charles poked fun at the Society "for spending time only in weighing of ayre". There were other and more serious criticisms, in the early years, of the unsubstantial quality of many of the papers published, to which were added financial troubles, and problems of accommodation. Despite the reputation of Newton and the prestige conferred upon it by his presidency, the Society had many difficulties and some opposition with which to contend before it became firmly established. Later, at the end of the eighteenth century, during the long and autocratic presidency of Sir Joseph Banks, there were acute dissensions among the members and strong criticism of the methods of election to fellowship.

Gradually, however, reforms were introduced; scientific attainment was established as the essential qualification for admission of the great majority of the members, and the leading men of science came into control of the administration. By the middle of the nineteenth century, despite the competing activities of the many specialized societies which were being formed, the Royal Society had achieved the position of unchallenged leadership and authority which it holds to-day.

This book is the more valuable because it is obviously the outcome of extensive reading and careful investigation. Miss Stimson has special reasons for her interest in the American contacts of the Society, and has given many interesting particulars of the membership of Cotton Mather, Benjamin Franklin, and other prominent Americans.

THOMAS MARTIN

APPLIED CHEMISTRY

Thorpe's Dictionary of Applied Chemistry

Fourth edition, revised and enlarged. Vol. 9: Oils, Fatty—Pituitary Body. With an Index by Dr. J. N. Goldsmith. Pp. viii+671. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1949.) 80*s*. net.

THE national importance of the chemical industry, and of those allied industries which depend upon chemical science, is reflected to-day in the pronouncements of Ministers and the figures of trade. Chemical technology becomes increasingly scientific, and chemistry constantly makes available new knowledge of materials and reactions. It is essential that this new knowledge should be assembled in a convenient form. Moreover, in these days when we are in danger of being overwhelmed by a mere mass of information, it is most valuable to have it filtered and screened by experts.

The appearance of a further volume of the new edition of "Thorpe" is therefore to be greeted with pleasure and gratitude, both because of the wide range and the authoritative treatment of the subject-matter. The present volume, No. 9 in the series, contains articles from some seventy authors, and the general level of the contributions may be indicated b some samples. Dr. E. J. Bowen writes on "Photochemistry", Dr. U. R. Evans on "Passivity", Prof T. P. Hilditch on "Oils and Fats", Prof. E. L. Hirs and Dr. J. R. N. Jones on "Pectin", and Mr. B. Tople and Dr. B. Raistrick on "Phosphorus". The inclusio of contributions from distinguished overseas author such as Prof. J. H. Quastel (oxidizing enzymes), D Gustav Egloff (petroleum), and Prof. R. J. William (pantothenic acid) is a pleasing feature. The centra position of chemistry in science is well exemplifie by a comparison of the largely mathematical articl of Dr. E. A. Moelwyn-Hughes on "Partition Function" with monographs from the biological end of th subject, such as that by Dr. E. Lester Smith and hi collaborators on "Penicillin".

Sir Ian Heilbron and his colleagues on the editoria board are to be congratulated on the general high leve of achievement. The world of chemistry is in debt t them and to the authors alike.

R. P. LINSTEAD

A STUDY OF IBO LIFE

Ibo Village Affairs

Chiefly with Reference to the Village of Umuek Agbaja. By M. M. Green. Pp. xi + 262. (London Sidgwick and Jackson, Ltd., 1947.) 10*s*. 6*d*. net.

THIS book is a valuable contribution to ou understanding of the Ibo, not for the facts i contains but for the very clear exposition Miss M. M Green gives in Part 1 (Village Organisation) of th general, almost conscious, tendency of the Ibo peopl to disperse authority over as many groups as possibl —whether based on age, sex, occupation or anythin else—rather than to concentrate it in the hands o any central organisation. There are, as she point out, no recognized bodies, either judicial or legislativ that function to the exclusion of other groups, fc any group "can take the initiative and win the day i they can secure enough popular support". Many the difficulties in establishing indirect rule in this pa of Nigeria might have been lessened, if not avoide if this had been fully appreciated earlier.

Parts 2 (Exogamy) and 3 (Women's Organisation are of less general application. The argument th the system of exogamy (whereby all the daughte are married into, and all the wives drawn from, oth villages) forms one of the strongest links by whic villages, in the absence of any political ties, a joined together is probably true of Umueke Agbaj and similar communities where the exogamous un is the village. Exogamy undoubtedly is a cohesi element; but its effect will obviously be of less politica and even social, importance in other parts of I country where the exogamous unit is the extend family and where large numbers of women spen their life in the village or village group in which the are born.

Miss Green adds an interesting appendix in whic she attempts to interpret the Ibo temperament the light of the conclusions reached by Dr. Mur Mackenzie, particularly in his book, "The Hum Mind". Her views are tentative and are, as it wer merely set out for our consideration. But they a certainly thought-provoking, and investigations alo the lines she suggests may well do much to raise t 'iron curtain' which all who have worked among t Ibo feel to exist between the minds of these peop and their own.

J. O. FIELD

NEW EVIDENCE ON THE STRUCTURE OF SOME PROTEINS FROM MEASUREMENTS WITH POLARIZED INFRA-RED RADIATION

By E. J. AMBROSE, Dr. A. ELLIOTT and Dr. R. B. TEMPLE
Research Laboratory, Courtaulds, Ltd., Maidenhead

CURRENT views on the structure of keratin, myosin and related proteins are based on chemical analyses and on X-ray diffraction data. The X-ray evidence (Astbury and Street[1]) shows that these proteins may exist in either of two forms, α and β, each of which shows a characteristic X-ray diffraction photograph. The most intense meridian reflexion corresponds to a chain spacing in the α-form of about 5·1 A., while in the β-form the chain spacing is about 3·3 A. Since it is possible, after suitable softening treatment, to change a natural protein in the α-form to the β-form by stretching or squeezing, it is generally assumed that the polypeptide chains in the α-form are folded in some way, whereas the β-form corresponds to the extended chain. Astbury[2] has proposed a particular form of folding for α-keratin; Huggins[3], Wrinch[4], and Wrinch and Jordan Lloyd[5] have suggested a number of other possibilities. In an interesting recent paper by Astbury, Dalgleish, Darmon and Sutherland[6] the properties of some synthetic polypeptides and natural proteins have been discussed, both from the point of view of X-ray diffraction and infra-red absorption.

We have been engaged in applying measurements made with polarized infra-red radiation to problems of high-polymer structure and have been working on synthetic polypeptides prepared in this laboratory (Hanby, Waley and Watson[7]). An interesting result observed in oriented polyglutamic ester and in α-keratin has already been briefly reported (Ambrose and Hanby[8]). In oriented (rolled) polyglutamic ester and in keratin obtained from porcupine quill, the preferred direction of the N—H bonds is shown by polarized infra-red measurements to be parallel to the chain orientation. This strongly supports the view that the backbone or chain is folded to form a seven-membered ring as indicated by them[8] and shown in Fig. 1. A fold of this kind differing from the above only in the arrangement of the side-groups has been suggested by Huggins[3]. The arrangement of the side-groups shown in Fig. 1 transforms more easily into the β-form and will fold about an axis parallel to the plane of the rings.

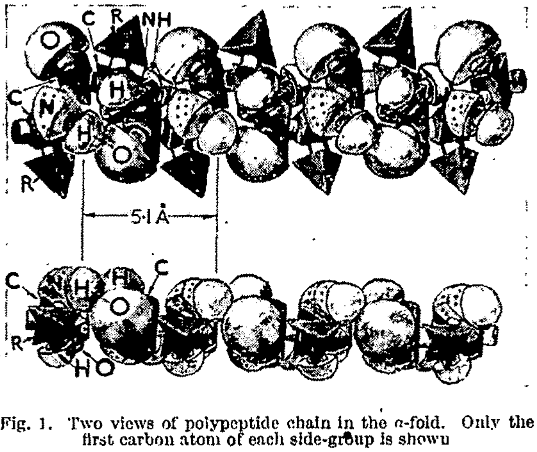

Fig. 1. Two views of polypeptide chain in the α-fold. Only the first carbon atom of each side-group is shown

In view of the importance of the interpretation of the α-structure, we have examined several proteins of the keratin–myosin group. The results, described below, are all in harmony with those obtained in the first instance with polyglutamic ester and α-keratin.

Experimental Evidence

The spectra were recorded in the 3-μ region with a lithium fluoride spectrometer equipped with a selenium transmission polarizer (Elliott, Ambrose and Temple[9]), and tracings are shown in Fig. 2. The keratin specimens were cut sections of porcupine quill (α-keratin) and of swan quill (β-keratin). For orienting specimens of myosin and tropomyosin, the proteins were cast on thin films of rubber, which were afterwards stretched. This technique, which we believe to be new, solved a difficult problem. It was found that cast films of tropomyosin often showed some orientation after drying; this is, no doubt, a consequence of the fact that the material forms fibrillar aggregates in solution (Astbury, Reed and Spark[10]). The myosin was prepared by Edsall's method[18], and tropomyosin was made according to the description given by Bailey[11].

The main features of all the spectra are the bands due to stretching frequencies of the C—H bonds at about 2,900 cm.$^{-1}$, and two bands which almost certainly arise from N—H stretching modes, a strong band at about 3,310 cm.$^{-1}$ and a much weaker one at about 3,060 cm.$^{-1}$. Both N—H bands show parallel dichroism in myosin, tropomyosin and α-keratin, but are markedly perpendicular in feather keratin, which occurs naturally in the β-form (Astbury and Marwick[12]) and is highly crystalline.

Interpretation of Spectra

These facts can be interpreted, as already stated, if it is assumed that the polypeptide chains are folded in the α-form and extended in the β-form. It may be argued that the differing dichroism may arise from the nitrogen atoms on the side-chains; but it is generally considered that the nitrogen is present in the side-groups as $\overset{+}{N}H_3$, and from observations which we have made on glycine ($\overset{+}{N}H_3\,CH_2\,\overset{-}{C}O_2$), the zwitterion form appears to give rise to a very broad absorption band extending from about 2,900 to 3,400 cm.$^{-1}$, with a maximum at 3,160 cm.$^{-1}$. It seems, therefore, that though the side-chain $\overset{+}{N}H_3$ will contribute to the general level of absorption, the bands at 3,060 cm.$^{-1}$ and 3,310 cm.$^{-1}$ can be attributed to the polypeptide N—H linkages. It appears reasonable to assume that in α-keratin and in the α-forms

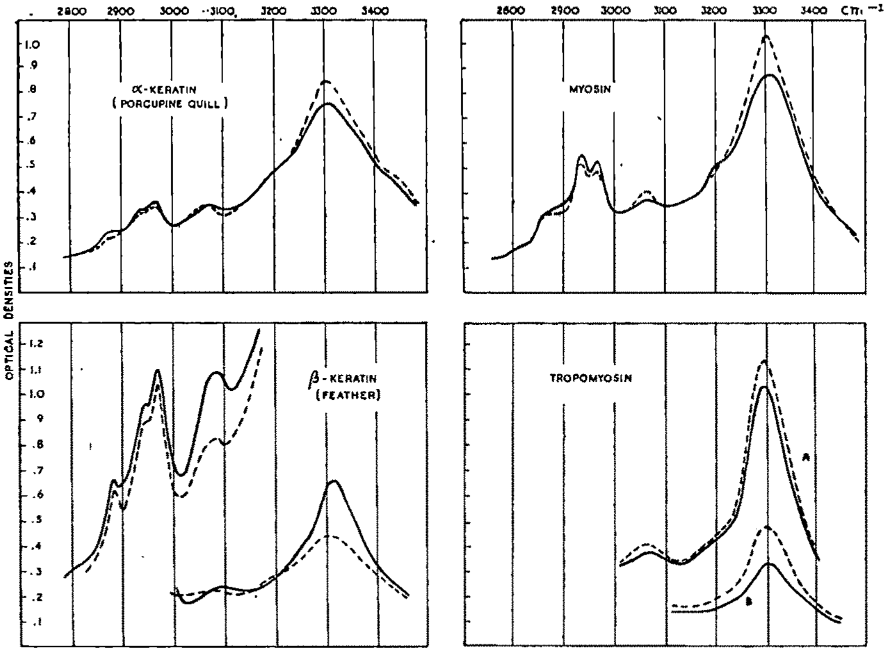

Fig. 2. Infra-red spectra of proteins, using polarized radiation. Full and broken lines show spectra with the *E*-vector respectively perpendicular and parallel to the chain axis. In the tropomyosin spectrum, *A* was obtained with a specimen self-oriented on drying; *B* was a thinner specimen stretched on rubber film. The high-frequency band in β-keratin was obtained with a thinner specimen than that used for the lower-frequency region

of myosin and tropomyosin the same backbone structure is found as in polyglutamic ester, since the same type of dichroism is found in the N—H bands in all these molecules. Without the work on a polypeptide in which there is no nitrogen on the side-groups, one would, however, hesitate to propose a structure for the protein backbone from the infra-red observations.

The weak band at 3,060 cm.$^{-1}$ is ascribed by Astbury, Dalgleish, Darmon and Sutherland[6] to a type of hydrogen-bonded N—H. It is sensitive to changes in structure; for example, Astbury *et al.* found that it weakened in tropomyosin on changing from the α- to the β-form, and we have found that it is weakened in nylons by melting, and by solution in *iso*butyl alcohol. In the proteins we have examined it shows the same type of dichroism as the strong N—H band, generally giving a somewhat higher dichroic ratio. Although a weak band, it may be structurally important, since the low frequency suggests strong hydrogen bonding.

Attention may be directed to the great similarity in the C—H stretching frequencies in α- and β-keratin (apart from the much higher density in the β-specimen caused by the use of a thicker specimen). The similarity of the three peaks includes frequency, relative intensity and dichroism. This may be taken to mean that the arrangement of the side-groups relative to the fibre axis is not greatly different in the two forms. The contrast with the N—H frequencies is striking.

Discussion of Proposed Model

The arrangement shown in Fig. 1 appears to be the one which will give the highest parallel dichroism for the N—H absorption bands. The structure proposed by Astbury[2] gives little preferred direction for the N—H bonds; other arrangements proposed by Huggins[3] as alternative to his '*a*'-fold would give low dichroism also. The spiral shown by Huggins in Fig. 13 of his paper also appears to give about the required amount of parallel dichroism. Although possibly fitting the X-ray observations rather better than the '*a*'-fold, this spiral has the serious objection that it is practically rigid. Moreover, the α–β transition would require that many of the side-chains would have to rotate through an angle of 180°, which in a material such as keratin containing numerous intermolecular cystine and salt linkages seems highly improbable. Calculation based on densities, unit-cell dimensions and residue weights do not allow a choice to be made between four or three residues per unit cell, and hence do not discriminate between the '*a*'-fold and the spiral. Although the dichroic ratios shown in Fig. 2 are not high, the result for tropomyosin shows a dichroic ratio almost as high as we have obtained for the same N—H band in a rolled nylon specimen, though in nylon, of course, the band is of perpendicular character. We have pointed out elsewhere[16] that in nylon (as in other polymers) the dichroism of many bands is not as high as the orientation of the crystalline regions would lead one to expect, taking into account the known direction of the covalent linkage involved, which, in the case of the nylon N—H linkage, is perpendicular to the chain axis. We feel, therefore, that the evidence favours the structure which would show the greatest parallel dichroism in the proteins examined.

X-Ray Data

The true repeating unit along the fibre axis for the model shown in Fig. 1 is 5·1 A. Huggins[3] considers that it is necessary to assume that alternate side-chains are more potent scatterers of X-rays in order to account for the intensity of the 5·1 A. reflexion. Possibly a slight bending or staggering of side-chains of neighbouring molecules resulting from *inter*-chain salt linkages will account for the intensity.

MacArthur[17] has resolved two strong equatorial reflexions of 9·2 and 10·5 A. spacing in α-keratin. One of these, possibly the 9·2 A. spacing, may correspond to the side-chain spacing as in β-keratin, while the other of 10·5 A. may correspond to the spacing between pairs of α-ribbon molecules. The α-ribbons will presumably run alternately parallel and anti-parallel (with respect to the —NH—CO—CH*R*— units along the chain), as they are thought to do in β-keratin (Huggins[3]). These pairs of chains may be packed in a hexagonal array; Perutz has discovered a hexagonal packing of α-folded chains in hæmoglobin crystals.

Fellows would have a special responsibility, if only by reason of their freedom from undergraduate teaching, to play a major part in advanced teaching and graduate studies, and the undertaking of major pieces of research.

A second main difference is that Nuffield is a graduate college. The College may have not more han forty Students at any one time, and these must be reading for the degrees of D.Phil., B.Litt. or B.Sc., or be otherwise engaged in or contemplating approved research. A purely graduate college is, of course, something of an experiment in Great Britain. It is particularly striking that the development should have taken place in a university whose main pride, and rightly so, is in its honours schools. But this year there are about a thousand students reading for advanced degrees in Oxford, the great majority being in medicine or science, so that while increasing the numbers passing through the various honours schools and maintaining the same high standard, the University is also making a major contribution to training of research workers. In medicine and the physical and natural sciences, the graduate finds a base and a place for meeting other researchers in his broad field in the hospital and the laboratories. In social studies he is liable to find himself rather isolated, particularly if he did not take his first degree in Oxford. He has his supervisor, but he loes not fit very easily into the college of which he is a member, for the great majority of the other students will be reading for their first degree. By being also associated with Nuffield College, however, he is brought into close contact with other advanced students in social studies. Already, by providing laily lunches at which Fellows and students eat ogether, by holding special seminars and in various other ways, the College is going some way to provide a corporate life for graduate students in social studies. When at some future date the buildings are complete, there will also be a residential centre.

The main problem at the moment is to find first-class graduates capable of undertaking advanced work in social studies and to keep hold of them. The College offers studentships which may be up to £300, according to needs. At present, however, there is a very heavy demand from Government departments, industry, the universities, and from many other quarters for those who have just graduated with good honours degrees in economics, etc. In many cases, when we have been fortunate enough to get hold of first-class graduates, they have gone off within one or two terms to some attractive university appointment. This is only to be expected at the moment, and we have been glad to have had such capable young men associated with us, even for a short time. It is probably true to say that many of those and of our existing Students would have been lost for university work if Nuffield College had not been able to give them financial aid, for though there are many scholarships and grants available to undergraduates, there is little money for the student who wishes to continue beyond his first degree. It is to be expected that as the present pressure of demand declines, more students will be available for postgraduate work in social studies.

One final point: the founder in his wisdom saw that research in social studies might well be arid unless the College was brought into direct and close contact with practical affairs. There is thus the phrase in the statute governing the College: "to encourage research . . . especially by making easier the co-operation of academic and non-academic persons". This co-operation is helped by the College having visiting Fellows, chosen for their ability to further research in the College by virtue of "their practical experience in the professions or in industry or commerce". They are full members of the College and its governing body. At the moment the College has six visiting Fellows: Lord Beveridge, Mr. Harold Clay, Sir Geoffrey Heyworth, Mr. Herbert Morrison, Sir Raymond Streat and Sir John Henry Woods. It is of great value to have such distinguished men of affairs as these associated with the College and willing to give help and advice in the studies being undertaken there. Another method of co-operation, which owes so much to Prof. G. D. H. Cole and Lord Lindsay, is the private conferences held from time to time. The College invites some forty or fifty people drawn from industry and commerce, government and public affairs and the universities to discuss one or more questions of current importance. During the summer two such week-end conferences are to be held to consider certain problems raised by large-scale organisations and the nationalized industries.

THE GENETICAL SOCIETY

THE Genetical Society holds its hundredth meeting in Cambridge on June 30 and July 1. A number of foreign guests are being invited to the meeting, at which it is planned to present a picture of the growth of genetics and its scope in Britain to-day.

The Society was founded in 1919 by William Bateson, its first president being the Earl of Balfour, whose name is also associated with genetics in the title of the Arthur Balfour chair at Cambridge. Lord Balfour held the office of president until his death in 1930, when he was succeeded by Prof. R. C. Punnett. Since that time it has been customary for the presidency to be held by a professional geneticist for a limited number of years.

The aim of the Society is "to promote the Advancement of Genetics and intercourse among persons interested in that science", and it accepts to membership those who are or have been engaged in genetical research or teaching in the applied genetical fields of plant and animal breeding, or are in other ways attached to the study of the subject. Ordinary membership is thus in no way narrowly restrictive, and, indeed, it now stands at nearly two hundred. In addition, there are twenty overseas members who between them cover most parts of the world. The Society also elects to honorary membership eminent geneticists both from Great Britain and from overseas.

The hundredth meeting is being held just thirty years after the Society was founded—an average of some three meetings a year. These meetings normally take one or other of three forms. For some of them members submit papers dealing with their own researches. Others are organised as symposia on subjects of general interest, contributions being arranged by invitation. These symposia have often been organised and held in collaboration with some other learned society. Thus, genes and chromosome behaviour have been discussed jointly with the Society for Experimental Biology, disease resistance as it relates to plant and animal breeding with the Association of Applied Biologists, the genetics of fungi with the Mycological Society, and micro-organisms with the

Biochemical Society. The third form, which is generally adopted for the summer meetings, is that of visits to genetical laboratories or other places of interest to geneticists. On these occasions primary emphasis is placed on seeing the work in progress and the methods which are used there.

The Genetical Society played a large part in the Seventh International Genetical Congress held in Edinburgh in 1939. It has also always taken the opportunity of inviting geneticists from overseas, who might be visiting Britain, to attend its meetings and to read papers. In this way many eminent geneticists have been the guests of the Society, including the two Nobel Laureates in genetics, T. H. Morgan and H. J. Muller. Since the War a still more positive international policy has been adopted. Scarcely, in fact, was the War over before, in November 1945, the Society held a conference to which were invited geneticists from most of the western European countries and from the United States. Accounts were presented of the progress of genetical work in Britain during the war years, and the foreign visitors described activities in their own countries. Coming when it did, this meeting was appreciated by all as being not only a very happy occasion, but also one of the greatest value in renewing personal exchange of views, and going far to remedy the difficulties caused by lack of free communication during the war years. A further and similarly successful international conference was arranged in 1948 on genetics in relation to cancer problems, this time in co-operation with the British Empire Cancer Campaign.

The history of the Genetical Society is one of steadily increasing membership and steadily widening interest. The growing importance of genetics for other branches of science has been reflected in the Society's co-operation with other bodies in joint discussions. The growing strength of genetics has equally been reflected in the international conferences that have been held. Genetics has, indeed, changed and grown profoundly in the last thirty years, and the process is accelerating rather than declining. The Genetical Society has a great part to play in these changes if it is to serve the science in the future as it has done in the past. It must not merely continue, but strengthen, its efforts to combine the well-established function of promoting intercourse among its members, and the special branches of the science that they practise, with the newer and broader purpose of presenting genetics as one of the focal points not only of biology as a whole, but also of agriculture, medicine and the non-biological sciences; and it must do so on no narrow national basis. The developments, especially of the last few years, show that the Society is aware of these growing responsibilities. Looking back over its first hundred meetings, it may justly face the future with confidence in its ability to meet the needs of the time.

OBITUARIES

Sir Wyndham Dunstan, K.C.M.G., F.R.S.

Sir Wyndham Rowland Dunstan, director of the Imperial Institute during 1903–24, who died on April 20, aged eighty-seven, rendered great service to the British overseas countries. Educated at Bedford School and abroad, Dunstan commenced a notable scientific career as an assistant in chemistry to Prof. Th. Redwood at the School of Pharmacy o the Pharmaceutical Society and succeeded him in 1885 as professor of chemistry, a position held for ten years, during which, in 1887, he became director of the Society's new research laboratories. Simultaneously, he held the post of demonstrator in the University laboratories, Oxford (1884), and in 1885 was appointed University lecturer in chemistry in its relation to medicine. The medical bias of his work was confirmed by his appointment to the professorship of chemistry at St. Thomas's Hospital (1892–1900). Dunstan's organising ability led him to serve as secretary of the Chemical Society (1893–1903), and he was a vice-president of the Society during 1904–06. He was a member of Council of the Royal Society and at the York meeting of the British Association in 1906 was president of the chemistry and agriculture section.

During the earlier years, Dunstan published many papers on the chemistry of drugs; but his major original work was done largely in collaboration with other workers, notably Prof. J. T. Cash, T. A. Henry, E. Goulding, F. H. Carr, H. Brown and A. E. Andrews. Much of the work, for example, that on the pharmacology of aconitine and its derivatives (with Cash), the Indian aconites, podophyllum, and *Hyoscyamus* alkaloids, was still of pharmacological and medical interest; but the research with Goulding on oximes was purely chemical in interest, and that in association with Henry on cyanogenesis in plants was a new field of much scientific and practical importance.

Sir Wyndham's real life-work, however, in which his abilities as man of affairs had full play, was done at the Imperial Institute, which was founded to investigate and display the raw materials of British overseas countries with a view to their commercial utilization. He was appointed director of the Scientific and Technical Department in 1896, and succeeded Sir Frederick Abel in the full directorship of the Institute in 1903. Possessed of clear insight, decision and driving power, he recognized promising lines of work, and, with the help of a staff devoted to the mission of the Institute, greatly extended the laboratory and intelligence services, established technical advisory committees and carried through investigations which have proved of great and lasting value to the overseas countries in developing their natural resources. Particularly valuable work was done in connexion with the much-needed extension of cotton cultivation, and Dunstan's reports on "British Cotton Cultivation" (1904 and 1908) and on "Cotton Cultivation of the World" (1910) summarized the position at those times. He was president of the International Association of Tropical Agriculture in 1910 and of the International Congress of Tropical Agriculture in 1914. In 1916 the circumstances of the War suggested an inquiry into the possibilities of increased use in Britain of certain Indian raw materials, and, at the invitation of the Secretary of State, Dunstan organised, through the Imperial Institute Committee for India, an inquiry into the subject, which resulted in a series of valuable reports. On the mineral side, Sir Wyndham's official "Report on the Coal Supply of India" was published in 1898. At his instance, and under the auspices of the Imperial Institute, Colonial mineral surveys were established in Nigeria, Nyasaland and Ceylon, which had important practical results and laid the foundations of the present Colonial geological surveys. Meanwhile, the quarterly *Bulletin of the Imperial*

Institute had been first issued in 1903, and this publication rapidly increased in importance.

Dunstan early recognized the potential educational value of the public exhibition galleries of the Imperial Institute. He secured the appointment of a scientific staff which commenced the reorganisation of the galleries, and under his direction set in train their evolution, which has advanced step by step with the economic and social development of the overseas countries. He was honorary treasurer and secretary of the Sudeley Committee, and furthered the objects of that body by appointing a guide lecturer in the galleries and encouraging conducted visits of school parties.

By official requests Dunstan visited Cyprus, Asia Minor, Ceylon, India and Newfoundland, and prepared reports on their economic development.

Sir Wyndham, together with Dr. A. Senier, was a founder and a vice-president of the Aristotelian Society. He married as his second wife Violet M. C. Hanbury Tracy, and she survives him.

S. E. Chandler

Sir Robert Robertson, K.B.E., F.R.S.

Robert Robertson passed away on April 28 after a short illness which ended a very strenuous life. He was working at his researches in the Davy Faraday Laboratory almost up to the last, although he was in his eightieth year. I was first associated with him in 1900 when he was directing the laboratory of the Royal Gunpowder Factory at Waltham Abbey. In those days, almost half a century ago, ideas as to scientific control in manufacture were very modest, and the scale of remuneration was even more modest; and so this important Government factory had a staff of five or six chemists only, and their duties were many and diverse.

While at Waltham Abbey, Robertson carried out an important investigation which cleared up the then obscure question of the stabilization of guncotton, and made it possible to rationalize the method of boiling. Together with his colleague, the late William Rintoul, he worked out in his own time a process and plant for the recovery of the acetone used in the manufacture of cordite, and this was installed in the Royal Gunpowder Factory.

In 1907 he was transferred to the Research Department at Woolwich Arsenal, which had been started a few years before, largely at the instigation of Lord Haldane, as a counterpoise to the German *Zentralstelle*. There he directed the laboratories, and his work was again concerned principally with explosives. He continued accurate determinations of the calorimetry of propellants, work which proved of great value during the First World War, when it became necessary to modify the composition of cordite on account of the shortage of acetone. T.N.T. having been adopted for filling high-explosive shells, the manufacturers in Great Britain had difficulty in making enough of it, so Robertson and his staff worked out a process and erected a pilot plant, which was copied on a very large scale at the new factories at Oldbury and Queensferry.

Robertson was elected to the Royal Society in 1917 and was made a K.B.E. in 1918. In 1921 he became Government Chemist, and the range and scope of his activities were greatly extended, but he also found time and energy to carry out researches after hours. With his colleagues he investigated the infra-red spectra of ammonia and phosphine, and so was a pioneer in a branch of physical chemistry which has now become a most important means of investigating molecular structures. He also made discoveries about the structure of diamonds.

In 1931 he was one of the organisers of the chemical section of the Faraday Centenary Exhibition held at the Albert Hall, London. His acquaintance with research workers and laboratories throughout the kingdom enabled him to help bring together a most interesting lot of exhibits, and he inspired the whole of his staff with his own enthusiasm.

He retired under the age limit in 1936, but his activities did not cease, and he continued his researches, now in the Davy Faraday Laboratory; and in 1937 he was appointed director of the Salters' Institute of Industrial Chemistry. The Second World War, however, stopped these researches, as he rejoined the Research Department and took charge of the branch of it which was opened at Swansea. He also became chairman of several research committees, an activity for which he was specially fitted. After the War he went back to his laboratory bench in Albemarle Street and resumed other activities; but even his vitality was ultimately exhausted.

One of Robertson's greatest fields of work was the Royal Institution, of which he was secretary during 1926–29, and treasurer until 1946. During this time he helped to raise a very large sum for rebuilding practically the whole of the Institution and endowing its work.

Robert Robertson was born at Cupar in 1869. In 1903 he married Kathleen Stannus; he leaves a son and a daughter.

Arthur Marshall

Dr. W. J. Perry

W. J. Perry's interest in anthropology developed while he was reading mathematics at Cambridge and had the good fortune to come into close contact with W. H. R. Rivers, when the latter was concerned with external sources of ritual and other cultural features in Melanesia and was interested in Elliot Smith's studies of archaic ritual in Egypt. Perry took up the whole question of evidence for the survival of elements of ancient Egyptian cults, beliefs and institutions in other parts of the world. For a while this was a leisure occupation, but on his invitation to join Elliot Smith at Manchester as reader in comparative religion, he was able to devote himself entirely to these questions, learning Dutch in order to make a detailed study of the Indonesian material, which he published in his first major work, "The Megalithic Culture of Indonesia" (Manchester, 1918).

Perry then proceeded on a programme of much wider scale which sought to demonstrate the diffusion of archaic cults as part of an early cultural complex throughout southern Asia, the Pacific and much of North America. His hypothesis concerning a world-wide archaic culture of predominantly Egyptian origin was set out with a wealth of detail in "The Children of the Sun" (1923), published at the time of his appointment as reader in cultural anthropology in the University of London. Perry's later work in London was increasingly hampered by severe illness, which compelled him to retire in 1939; but he made a number of supplementary studies, notably of the diffusion of agriculture, related crafts and ritual in prehistoric Europe in "The Growth of Civilisation" (1924) and of cosmological ideas among Oceanian and other peoples in "The Primordial Ocean" (1935).

It is now generally held that Perry, like Elliot Smith with whom he worked so closely in this field, over-simplified the processes of cultural diffusion, and sometimes too readily assumed that similarities of a general or formal kind, such as the practice of similar crafts or beliefs in sky beings, were indubitable evidence of particular connexions and unitary origins. The insistence on an exclusively Egyptian source for archaic cultural features also unfortunately rendered many of his generalizations unacceptable to specialists on the early cultures of the ancient East, on which new excavations and comparative studies were accumulating a wealth of fresh material. Controversies as to Egyptian versus Sumerian or Babylonian origins often side-tracked the opportunity for collaboration between prehistorians and ethnologists in the comparative study of relations between prehistoric and living civilizations in southern Asia. But the late A. M. Hocart brought strong support for some of Perry's contentions in his comparative studies based on field research on coronation rites and other archaic ceremonials in India, Ceylon an Oceania.

Even though it be held that he claimed too much Perry's studies established the importance of earl centres of higher civilizations as factors in shapin the form and symbolism of human cult and belie over wide areas of so-called primitive culture. In th years that have followed, interest in cultural anthropology in Britain has moved strongly in othe directions; but Perry will be remembered for hi passionate convictions, his amazing industry, hi vigour as a controversialist and not least for hi warm humanity as a colleague. DARYLL FORDE

WE regret to announce the following deaths:

Dr. Norman R. Campbell, formerly of the Researc Laboratories of the General Electric Co., Ltd. Wembley, on May 18, aged sixty-nine.

Mrs. Nernst, widow of Prof. Walther Nernst For.Mem.R.S., who had been living with her daughte for the past three years in Wimbledon, Surrey, o May 4.

NEWS and VIEWS

Physical Society's Duddell Medal: Dr. E. H. Land

THE Duddell Medal for 1949 of the Physical Society was presented on June 2 to Dr. Edwin Herbert Land, inventor of the polarizing material 'Polaroid'. Though attempts had been made by previous workers to replace the costly and limited Nicol prism with dichroic substances in the form of thin laminæ, Land was the first to demonstrate the possibility of manufacturing such laminæ with sub-microscopic dichroic crystals of quinine iodosulphate correctly oriented to simulate a single crystal extended to a superficial area previously considered impossible. This method is now being superseded as the result of two stages of further development. In the first, a plastic medium is stretched to cause orientation of the micelles. It is then soaked in a solution of the iodonium compound, which is precipitated on the oriented micelles to produce a polarizing medium. In the final method, a stretched plastic medium is treated in a way which converts about 1 per cent of its bulk to a polyvinylene compound, a straight-chain polymer in which the double-bonded oxygen gives the necessary intense directional light absorption. It is claimed that this material is extremely heat-stable and very efficient. The light transmission of the single sheet is about 40 per cent, and is reduced to 0·02 per cent for two sheets in the crossed position. This is a very remarkable development of the original idea. First, Land has succeeded in eliminating the step of orienting sub-microscopic crystals of the iodonium compound; secondly, he has eliminated the compound altogether.

Land has also described an ingenious system of stereoscopic photography in which the two images are formed in two layers of polarizing crystals crossed with respect to each other and mounted on an aluminium background. Stereoscopic pictures on this principle were developed by the Polaroid Corporation under the name of 'vectographs' (*J. Opt. Soc. Amer.*, **30**, 230; 1940). A further novel development described by Land is a one-step photographic proces in which the positive print can be produced in abou one minute from the time the photograph is taken In this system, the processing is carried out b feeding the negative and the printing paper betwee pressure rollers, the reagent being spread in th form of a viscous liquid between the negative an positive emulsions (*J. Opt. Soc. Amer.*, **37**, 61 1947).

National Geographic Magazine and Dr. Gilber Grosvenor

DR. GILBERT GROSVENOR, president of the Nationa Geographic Society of Washington, D.C., was presented with a medal named after him at a ceremon on May 17, to mark his completing half a century a editor of the *National Geographic Magazine*. Th *Magazine*, which is really of his making, now has circulation of about two million copies a month. I was in 1899 that the President of the Society at th time was concerned about its official organ, whic had only a trivial circulation and no funds behind it The president in those days, who was A. Graham Bell, of telephone fame, appointed as editor o the *Magazine* a young, untried, but not untravelled man. Since then Dr. Grosvenor has built up th reputation and circulation of this finely illustrate journal, which is known throughout the world fo the excellence of its photographic illustrations and it colour plates. After five or six precarious years, th corner was turned about 1905 and the circulatio steadily grew. Dr. Grosvenor has collected photographs from every corner of the globe and articles b many eminent travellers. He has also edited a serie of large-scale detailed political maps issued with th *Magazine* from time to time, which have a wid circulation and use, and are notable for their accuracy The profits of this successful publication have bee largely devoted to exploration and research in variou lands and seas.

Marine Biological Station at Bangor: Dr. F. Gross

Dr. Fabius Gross, who has since 1937 been lecturer in experimental zoology in the University of Edinburgh, has been appointed director of the new Marine Biological Station to be erected on the Menai Strait at Bangor. The Station, while under the immediate control of the University College of North Wales, will be managed by a committee representing the biological departments of the constituent colleges of the University of Wales, and it is likely to become a vital link in the chain of British marine stations. Apart from its function in promoting educational facilities for the students of the University and others, it will conduct and encourage research, particularly in the almost unexplored field of marine microbiology, in which botanical and zoological studies meet. It will thus be in a position to make great contributions to fundamental knowledge as well as to the practical basis of fishery research, for there can be little doubt that the food-chains which ultimately produce our fish stocks have their biological origin in the microplankton.

Dr. Gross is eminently qualified to direct the work of the Station. His zoological studies in the University of Vienna under Profs. Storch, Versluys, Przibram and Joseph, and his researches there and in the Kaiser Wilhelm Institut für Biologie in Berlin, laid the foundation for experimental investigations of feeding, swimming movements, variation and regeneration in various aquatic invertebrates. Since he came to Britain in 1933, he has turned his attention particularly to culture methods for marine organisms, and this led to the war-time research, conducted by a team partly from the Department of Zoology in the University of Edinburgh and from Millport Marine Station, into the effect upon food-chains culminating in food fishes of the addition of inorganic nutrients to restricted sea areas. His extensive experience of British marine stations has been supplemented by large-scale plankton culture at the Oceanographic Institute at Göteborg in Sweden, and he has been invited to spend the present summer in collaborative work at the Oceanographical Laboratory at Woods Hole.

Linnean Society of London

Prof. Otto Jaag, of the Federal Technical High-school, Zurich, and Dr. David Fairchild, senior agricultural explorer to the U.S. Department of Agriculture, have been elected foreign members of the Linnean Society. Prof. Jaag is distinguished for his researches in limnology, and is editor of the *Schweizerische Zeitschrift für Hydrologie*. Dr. Fairchild, now eighty years of age, is distinguished for his labours in botany in its relation to horticulture. He has introduced many thousands of useful and ornamental plants into the United States. As an author, in addition to his scientific papers, he has published five books dealing with his travels in search of plants.

Two new associates *honoris causa*, the list of whom has never exceeded twenty-five, have also been elected by the Linnean Society; they are Dr. Robert Lloyd Praeger, of Dublin, distinguished for his long and thorough work on the flora of Ireland, and for his monographs of *Sedum* and *Sempervivum*; and Dr. Arvid Hjalmar Uggla, of Uppsala, distinguished for his researches on the work, writings and life of Linnæus. Dr. Uggla is the secretary of the Svenska Linné-sällskapet and editor of that Society's *Årsskrift*; and is at present working on a complete catalogue of the known manuscripts of Linnæus.

Disk for the Isaac Newton Telescope

Sir Harold Spencer Jones, Astronomer Royal, has recently spent three months in the United States, at the invitation of many American astronomers, in the course of which he visited most of the astronomical observatories, studying programmes of work and, in particular, the design and performance of large telescopes in connexion with the design, now under consideration, of the Isaac Newton reflector. During his visit he received the gift of a 98-in. 'Pyrex' glass disk for use in this telescope. The disk, which was cast before the War by the Corning Glass Co., was originally intended for use in a large reflector for the Michigan Observatory, a project which for various reasons was later abandoned. Its cost had been defrayed from the McGregor Fund. Judge Henry Hulbert, president of the Trustees of the McGregor Fund, informed the Astronomer Royal that the Trustees had unanimously resolved to make an outright gift of the disk, together with a 26½-in. disk for a secondary mirror and the central plug from the large disk, to the Royal Greenwich Observatory, for use in the Isaac Newton telescope. This generous gift, which has been gratefully accepted, should enable the telescope to be completed and brought into use some two or three years before it would otherwise have been possible. It is a symbol of the good-will on the part of the United States towards Great Britain, which the Astronomer Royal found everywhere in the course of his visit, and of the desire for close co-operation between the astronomers of the two countries.

Gamma-emitting Materials for Industry

A preliminary announcement has already been made by the Ministry of Supply on the sale of radioactive products for industrial radiography (see *Nature*, May 7, p. 717). A paper dealing with the supply and uses of radium and radon for industry is now being distributed by the Ministry to trade associations, professional institutes and research centres. Points of interest arising from this paper are the different physical properties of radium and radon. Though they both emit gamma-rays of identical quality, the radiation of the former is constant, whereas that of the latter has a half-life period of 3·8 days. This means that the effective life of radon is a little more than a week, but this is an advantage in, say, field-work where the loss of a capsule would not be serious, nor comparatively dangerous (in contrast to radium). The disadvantage of the variable strength of radon is further offset by the fact that, for equal intensities, it is of much smaller bulk than radium; hence, for radiographs of equal resolution, radon can be used much closer to the object under test, with a corresponding reduction in exposure-time. Radium may be obtained, on hire only and after notice of two months, for periods of not less than six months; capsules containing 50 mgm. and 250 mgm. are hired for £11 5*s*. and £56 5*s*. per year, with an additional fabrication and testing charge of £20 and £100, respectively. Radon is sold outright, typical costs being £15, £20 and £25 for sources of 250, 500 and 750 millicuries, respectively. Both materials can be obtained from the Radiochemical Centre, White Lion Road, Amersham, Bucks. Gamma-radiography requires skilled personnel for the handling of materials, interpretation of radiographs, etc., and, so far as is known, the only institution in Britain at present offering training facilities is the Kodak School of Engineering Radiography, Wealdstone, Harrow, Middlesex. Advice on the use of gamma-radiography (demonstrations are given) may be obtained from the Superintendent of Radiology Research, Ministry of Supply, Armament Research Establishment, Woolwich, London, S.E.18, and also from the Director, National Physical Laboratory, Teddington, Middlesex.

Gasteromycetes of Greenland

MORTEN LANGE has published a critical survey of the Gasteromycetes found in Greenland prior to the expedition of 1946 (*Medd. Grønland*, 147, No. 4, pp. 32+4 pl. København: C. A. Reitzels Forlag, 1948. Kr. 2.00). Thirteen species are described in detail. Most of them have European or North American affinities, though *Calvatia tatrensis* var. *groenlandica* is practically confined to Greenland. Some earlier records are reviewed, and their naming compared with modern standards.

University of Birmingham: Appointments

THE following announcements have been recently made in the University of Birmingham. The title of reader in renal physiology has been conferred on J. A. Barclay, lecturer in physiology. *Appointments:* F. J. Dyson to be research fellow in mathematical physics; J. T. Allanson to be lecturer in electrical engineering; B. H. Pethica to be lecturer in pharmacology; R. J. Boscott to be lecturer in endocrine chemistry. *Resignations:* Dr. H. B. Whittington, lecturer in geology, on appointment as visiting lecturer in geology at Harvard University; C. D. Cruikshank, lecturer in bacteriology, on appointment as assistant pathologist at the Selly Oak Hospital; S. Harper, lecturer in metallurgy, on appointment as research fellow at the University of Chicago; M. A. Preston, assistant lecturer in mathematical physics, on appointment as assistant professor in the Department of Physics, University of Toronto; P. L. Adams, lecturer in mining, on appointment as senior lecturer in charge of mining in the University of Sydney; S. R. Cornick, a member of the physics technical staff for thirty years and steward of the Department since 1937, on appointment as chief technical officer to the Australian National University at Canberra.

Institute of Metals

THE Institute of Metals has appointed the following to be honorary corresponding members for their respective countries: *Spain*, Prof. J. Orland, professor and chief of the Department of Metallography and Strength of Materials, Instituto Católico de Artes e Industrias, Madrid; *Sweden*, Prof. A. G. E. Hultgren, professor of metallography, Tekniska Högskolan, Stockholm; *United States*, Prof. R. F. Mehl, director of the Metals Research Laboratory and head of the Department of Metallurgical Engineering, Carnegie Institute of Technology, Pittsburgh, and Dr. R. A. Wilkins, vice-president (research and development), Revere Copper and Brass, Inc., Rome, N.Y.

Royal Aeronautical Society

THE Council of the Royal Aeronautical Society for the year 1949–50 has been announced as follows: *President*, Sir John S. Buchanan; *Past Presidents*, Dr. H. Roxbee Cox, Sir Frederick Handley Page; *Vice-Presidents*, Mr. W. G. A. Perring, Mr. N. E. Rowe, Dr. H. C. Watts; *Council Members*, Lord Brabazon of Tara, Major G. P. Bulman, Mr. S. Camm, Mr. A. V. Cleaver, Dr. G. P. Douglas, Mr. G. R. Edwards, Mr. A. G. Elliott, Mr. W. S. Farren, Sir A. H. Roy Fedden, Sir Arthur Gouge, Major F. B. Halford, Prof. A. A. Hall, Mr. S. Scott Hall, Mr. J. W. F. Housego, Mr. P. G. Masefield, Mr. W. Tye, Capt. C. F. Uwins; *Honorary Librarian*, Mr. J. E. Hodgson; *Honorary Treasurer*, Capt. C. F. Uwins; *Solicitor*, Mr. L. A. Wingfield; *Secretary*, Capt. J. Laurence Pritchard.

Announcements

PROF. H. P. HIMSWORTH has been appointed by the Medical Research Council to be its secretary in succession to Sir Edward Mellanby, who retires on October 1. Dr. Himsworth is at present professor of medicine in the University of London and director of the Medical Unit at University College Hospital; he has been a member of the Council since February 1948.

THE Thomas Young Oration for 1949 of the Physical Society will be delivered by Mr. T. Smith on June 10; he will take as his subject "The Contributions of Thomas Young to Geometrical Optics, and their Application to Present-day Questions".

THE Royal Astronomical Society is arranging meetings to be held during June 30–July 2 in Manchester, in co-operation with the University of Manchester and the Manchester Astronomical Society. The programme includes a public lecture at the University, to be given by Dr. M. A. Ellison, of the Royal Observatory, Edinburgh, on "Sun, Radio and the Stars", on June 30; a visit to Jodrell Bank Experimental Station on the morning of July 1, followed by an ordinary meeting of the Royal Astronomical Society, and a dinner given by the Vice-Chancellor of the University; and a Geophysical Discussion on "Ionization in the Earth's Upper Atmosphere", to be held on July 2. Further information can be obtained from the Assistant Secretary, Royal Astronomical Society, Burlington House, London, W.1.

A CONFERENCE on "The Properties of Semi-Conducting Materials" is to be held at the University of Reading during July 11–14, 1950. The conference will be sponsored by the International Union of Physics, in co-operation with the Council of the Royal Society. It is hoped that papers will be read by prominent representatives from the United States and European countries. Details will be published later.

THE Royal Aeronautical Society announces that a scholarship to be known as the Royal Aeronautical Society Charter Scholarship, up to the value of £300 a year, will be awarded annually to assist a student wishing to undertake advanced work or study in aeronautics. Normally, the work should lead to a higher degree or postgraduate diploma, although this is not essential. Scholarships will in the first instance be awarded for a period of one year. Applications should reach the Secretary of the Society not later than June 30, stating the course it is intended to follow.

ERRATUM. In *Nature* of May 28, p. 833, it was stated that a summer school on electron microscopy will be held at the Cavendish Laboratory, Cambridge; the dates for this school are August 16–27.

High-Energy Electron Accelerators as Pulsed Neutron Sources

In the time-of-flight method of distinguishing between neutrons of different energies, various types of pulsed neutron sources have been used. So far, however, the use of pulsed sources of high-energy electrons for generating neutrons through the (γ, n) reaction has not been reported. Experiments reported in the following letter show that the X-rays from a 3- or 4-MeV. linear accelerator will produce useful intensities of neutrons from a beryllium target.

From these results it would appear that a 10-MeV. linear accelerator would provide a suitable source.

By such means, time-of-flight measurements could be made with reasonable resolutions up to energies hitherto unobtainable.

J. D. Cockcroft

In the preceding letter, Sir John Cockcroft discusses the possibility of using high-energy electron accelerators as pulsed neutron sources. To investigate the potentialities of the method, measurements have been made on the linear electron accelerator at this Establishment[1]. An experiment was performed when the accelerator was providing 100 m.amp. peak current in a 2-μsec. pulse of electrons of energy 3·2 MeV. The electrons were absorbed in a lead target, and the resulting X-radiation was absorbed in a container about 13 in. long (in the direction of the beam) and 5 in. square. The container was filled either with heavy water or with beryllium scraps, the latter giving a density of about 0·7 gm./c.c. The neutrons produced were absorbed in manganese sulphate solution in a tank surrounding the container. The neutron production was measured by comparing the activity of the manganese solution with that produced by a 200-mgm. radium – beryllium source inserted in place of the container.

Under these conditions, calculations based on the Bethe – Heitler theory of X-ray production from electrons predict a peak neutron production in the pulse of about 3×10^{12} neutrons per sec. (for heavy-water target). The experimentally determined value was $2 \times 10^{12} \pm 25$ per cent neutrons per second, the error being due partly to uncertain calibration of the radium – beryllium source and partly to uncertainties in the comparative geometry in the main and calibration runs. The beryllium target gave a neutron production 30 per cent lower than that from the heavy water.

It is apparent, therefore, that this method holds great promise for time-of-flight measurements. With higher energy linear accelerators, measurements with good resolution up to neutron energies of 20 keV. or more should be possible. Moreover, the high electron currents available at low pulsing-rates on machines using Marx-type generators might provide neutron sources of sufficient strength to work up into the 100-keV. region. The low pulse-rate would be a disadvantage, but measurements would be possible using very long time-of-flight paths, or, alternatively, a shorter path coupled with a short pulse and a high-resolution detector.

Effect of X-Rays on the Incorporation of Carbon-14 into Desoxyribonucleic Acid

It was observed by several experimenters[1] that the incorporation of phosphorus-32 into desoxyribonucleic acid of the Jensen sarcoma, and also of normal organs, of the rat is markedly reduced by irradiation with an X-ray dose of some hundred röntgens. This result strongly suggests the explanation that the rate of formation of desoxyribonucleic acid is reduced by the effect of ionizing radiation, though the objection may be raised that it is the re-phosphorylation of the molecule during incorporation of labelled phosphate which is hampered, and not the formation or the assembly of the main constituents of the nucleic acid molecule. To avoid this objection, the effect of X-rays on the incorporation of carbon-14 into the purines of desoxyribonucleic acid in the organs of rapidly growing rats has been studied.

About five microcuries of carbon-14 incorporated with the carboxyl group of sodium acetate were injected subcutaneously to each of 91 one- to three-week-old rats. The rats were killed after the lapse of six hours, and the desoxyribonucleotides were separated from the proteins by extraction with hot trichloroacetic acid[2]; the purines obtained by hydrolysis were twice precipitated as silver salts and their radioactivity was measured. Previous to the extraction of the kidney and muscle proteins, 20 mgm. of desoxyribonucleic acid, kindly presented by Prof. Hammarsten, were added to the trichloroacetic acid extract. Half the rats were previously irradiated with a dose of 950 r., the voltage applied being 165 kV.

As shown by the figures in the accompanying table, the amount of labelled purines formed in the irradiated rats was about half the amount formed in the con-

Ratio of carbon-14 content of 1 mgm. of purine isolated from desoxyribonucleic acid of non-irradiated and irradiated rats six hours after administration of about 0·4 mgm. of labelled carbon as acetate to each of 91 one- to three-week-old rats

Organ	Ratio of C^{14} content of purine from desoxyribonucleic acid isolated from non-irradiated and irradiated rats, respectively				Ratio of C^{14} content of 1 mgm. protein from organs of non-irradiated and irradiated rats, respectively		
	Group 1	Group 2	Group 3	Group 4	Group 2	Group 3	Group 4
Intestinal mucosa	2·3	2·0	2·2	1·5	0·78	0·80	0·90
Liver	2·3	2·0	1·5	1·5		0·83	0·50
Muscles			3·1	1·8		0·91	1·0
Kidneys	1·0		3·0	3·7		1·0	1·0

Percentage of administered C^{14} incorporated in 1 mgm. intestinal mucosa

	Purine min.	Purine max.	Protein min.	Protein max.
Non-irradiated	$3 \cdot 7 \times 10^{-5}$	$2 \cdot 4 \times 10^{-4}$	$4 \cdot 1 \times 10^{-4}$	$6 \cdot 3 \times 10^{-4}$
Irradiated	$1 \cdot 7 \times 10^{-5}$	$1 \cdot 3 \times 10^{-4}$	$5 \cdot 2 \times 10^{-4}$	$7 \cdot 8 \times 10^{-4}$

trols, which is very similar to the reduction in the incorporation of phosphorus-32 observed earlier[1].

The rate of incorporation of carbon-14 into the proteins was not reduced by irradiation; even some increase was observed, which may be due to a decrease in the metabolic-rate produced by irradiation and leading to an increased level of carbon-14 in the liver and intestinal mucosa, corresponding to a greater incorporation of carbon-14 into the proteins of these organs. The fact that, despite the increased carbon-14 content of the proteins of the irradiated rat, we observed a markedly reduced incorporation of carbon-14 into the purines of desoxyribonucleic acid of such rats clearly indicates a reduced rate of formation of the last-mentioned compound in the irradiated animal. The observation that the rate of formation of a main constituent of cell nuclei is reduced appreciably after irradiation helps to explain the blocking effect of irradiation on cell division and the formation of anomalous mitotic products in the irradiated tissue.

In this connexion it may be of interest to recall that the hypothesis of nucleic acid starvation was recently put forward by Darlington[3], who assumes the chromosomes to vary in their behaviour and appearance according to nucleic acid supply available.

My thanks are due to Miss G. Dreyfus for very effective assistance.

Surface Transport of Liquid Helium II

RECENTLY, Atkins[1] has reported transport-rates in helium films which were many times greater than those observed under somewhat similar conditions by J. G. Daunt and one of us[2]. Moreover, these rates were not constant, as in our experiments, but evidently varied in a complex manner with the length of the film. Atkins used glass beakers which, in contradistinction to our original experiments, ended in a large bulb. He ascribed the phenomena observed by him as being due to the geometrical arrangement and connected with the temperature gradient in the film, supporting this suggestion by a separate experiment. Lately, de Haas and van den Berg[3] have also observed such high transfer-rates. It appears that there was no temperature gradient in their experiment, and they attribute the high rate to the complete absence of incident radiation.

A systematic study of the factors affecting the film transfer has been in progress in this Laboratory for more than two years, and it may therefore be of interest to compare our results with the above-mentioned observations. First, we have found *no* indication that high transport-rates are caused by a temperature gradient[4]. Secondly, we found that the transfer-rate of a narrow beaker was *unchanged* after a bulb had been attached to it. Thirdly, we found that the transfer-rate remained *unchanged* even when radiation was excluded completely.

It thus appears that beside the frictionless film transfer with a maximum transport-rate of about 10^{-4} cm.^{3}/cm./sec., which has consistently been observed by us in well over a hundred individual experiments, there can occur occasionally a surface flow reaching much higher rates and of more complex aspect. However, the curious fact remained that our results differ from those of Atkins and the Leyden workers, although our experimental arrangements conformed with the conditions postulated by these authors as causing high rates of flow. This seemed to indicate that the real reason for the appearance of high flow-rates has to be sought in some subtle difference in experimental technique. Observations by J. O. Closs and one of us[5] of a desorption of helium layers, probably akin to the film later discovered by Rollin and Simon[6], already showed the strong dependence of this desorption on the state of the surface. A careful analysis of all experiments in which a high transfer-rate seems to have occurred suggested to us that the real cause of this effect might be found in the condition of the solid surface carrying the transfer, and in particular in the contamination with condensed gases. In order to investigate this point, we carried out a standard transfer experiment with a cylindrical glass beaker, out of which helium flowed into the surrounding bath. The rate of transfer was again found to be in good agreement with our previous work. Then some helium gas containing a small amount of air was introduced into the cryostat, and a thin layer of solid air was deposited on the beaker. A repetition of the previous experiment showed that the character of the transfer had now completely changed. The initial transport-rate had increased about ten times, and varied with the distance of the higher level from the rim of the beaker, as observed by Atkins. Subsequent observations have shown that: (1) On depositing successive thin layers of solid air, the transfer changes gradually from the normal type to that observed in Cambridge and Leyden. (2) Beyond a certain thickness of the layer of solid air, the transfer does not increase with further deposition. (3) The layers of solid air up to the thickness which gives the saturation transport-rate are completely transparent and colourless. The appearance of still thicker layers suggests that the deposit is granular with a grain-size of the order of the wave-length of light. (4) An adsorbed layer of air deposited on the glass surface at 90° K. slightly increases the transport-rate.

These results, together with our inability to obtain high transport-rates in the earlier experiments, seem to leave no doubt that the phenomena observed in Cambridge and Leyden are entirely due to contamination of the surfaces employed and have, to some extent, lost the character of pure film transfer. While thus, in our opinion, these high transport-rates are spurious effects which may be difficult to interpret in a quantitative manner, the phenomenon is of considerable importance for cryogenic technique. We observed that after the introduction of impure helium which had deposited a layer of solid air, not only on the beaker, but also on the walls of the cryostat and the pumping tube, the evaporation of helium was greatly increased owing to the higher transfer along the walls. Clearly, the recognition of the real cause of high transport-rates and its avoidance is of particular importance for experiments below 1° K.[7]. A letailed discussion of our experiments and their mplications will be published elsewhere.

Strengths of Metals

No experimental method has been suggested for recording directly the pure diffraction broadenings of X-ray reflexions; there is always an appreciable amount of broadening due to experimental conditions, and the diffraction broadening has to be disentangled from the total broadening by various procedures[1,2]. In any statement of results, therefore, it is essential that the particular procedure used should be stated, so that even if other workers think it unsatisfactory they should at least have some basis for comparison with their own results.

Wood and Rachinger do not give such experimental details in the results they have recently published[3]. In re-stating the claim that the broadening of X-ray reflexions from cold-worked metals is due to the smallness of the crystallites into which the grains are broken, they make no reference to our critical comments[4] on evidence previously given[5] in support of this claim, nor to the considerable amount of experimental work[6–9] which points to inhomogeneous internal strains as the principal cause of the broadening.

There still remains, however, the striking agreement obtained for the yield stresses of a number of metals when the values of Wood's 'limiting crystallite size' are substituted in the expression that Bragg[10] has derived theoretically. The main purpose of this present communication is to show that this agreement results also from the theory that the broadening of the reflexions is due to inhomogeneous internal stresses, the argument being as follows.

Wood's 'limiting crystallite size' t may be regarded as a parameter related to the broadening β by the relation

$$t = \lambda/\beta \cos\theta, \tag{1}$$

where λ is the wave-length of the radiation, and θ is the Bragg angle. (In effect, this is Wood's original definition, but the unfortunate name he proposed for the parameter has been the cause of much misconception.) In Bragg's theory of the strength of metals[10], it is shown that the yield stress Y should be related to the true crystallite size t_c by the expression

$$Y = ns/t_c, \tag{2}$$

where n is the rigidity and s is the atomic diameter. If Wood's values for t are substituted for t_c, Bragg showed that the correct order of magnitude for Y is given for a number of metals.

Combining equations (1) and (2), we have

$$Y = ns\beta \cos\theta/\lambda. \tag{3}$$

Now, according to Stokes, Pascoe and Lipson[7], the yield stress should be related to β by the expression

$$Y = E\beta \cot\theta, \tag{4}$$

where E is Young's modulus, which for the present purpose may be regarded as constant.

Equations (3) and (4) may be written as

$$\left.\begin{aligned} Y &= \frac{ns}{\lambda}\,\beta\cos\theta \\ \text{and } Y &= \frac{E}{\sin\theta}\,\beta\cos\theta \end{aligned}\right\} \tag{5}$$

and it can be shown that ns/λ and $E/\sin\theta$ are approximately equal for the conditions of Wood's experiments.

The ratio of these quantities is

$$\frac{ns\sin\theta}{E\lambda} = \frac{1}{2(1+\sigma)}\,\frac{s}{\lambda}\sin\theta, \tag{6}$$

where σ is Poisson's ratio. Sin θ is almost exactly unity, because Wood uses only the back reflexions, and, since $\sigma \simeq 0{\cdot}3$,

$$\frac{ns\sin\theta}{E\lambda} \simeq 0{\cdot}4\,\frac{s}{\lambda}. \tag{7}$$

For most of the metals considered, $s \simeq 2{\cdot}5$ A., but λ, of course, is different for different radiations. We may, however, take the two radiations quoted by Wood[5] as examples; for cobalt $K\alpha$, $0{\cdot}4s/\lambda \simeq 0{\cdot}55$, and for molybdenum $K\alpha$, $0{\cdot}4s/\lambda \simeq 1{\cdot}4$. Thus the coefficients of equations (5) are approximately equal, and approximately correct values of Y follow from either of them.

In order to distinguish between the two equations, qualitative work is useless; quantitative results, for the variation of β with both θ and λ, are necessary, and we believe that these results have already been produced in the papers quoted in this communication.

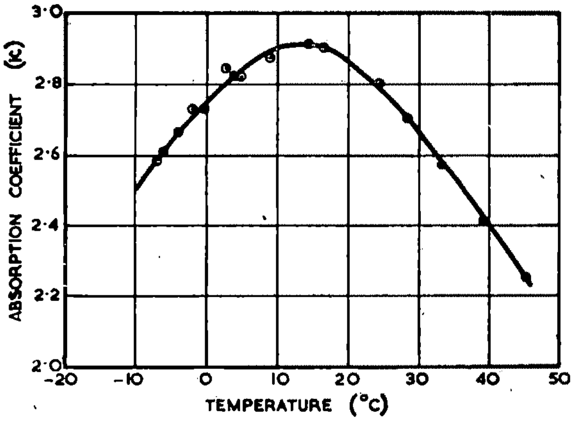
Absorption of 12·5-mm. Wave-length Electromagnetic Radiation in Supercooled Water

We have recently succeeded in measuring the absorption of radio waves of wave-length 12·5 mm. in transmission through water in the supercooled state in layers of varying thickness up to several millimetres: the lowest water temperature so far reached in this work is − 7° C.

The complex refractive index of an absorbing medium may be expressed as $(n - j\varkappa)$, and our measurements have led to a determination of the absorption coefficient $\varkappa$. It is well known that if such an absorbing medium is inserted in a wave-guide, completely filling it over a portion of its length, the rate of attenuation of waves passing through the medium is, in general, dependent both upon $\varkappa$ and upon the refractive index n. If the lateral dimensions of the wave-guide are sufficiently great, however, it may be shown that the absorption coefficient determined by measuring the rate of attenuation in a system such as this differs by a negligible amount from the value of $\varkappa$ pertaining to a medium of infinite extent. We have used this method, the diameter of the cylindrical wave-guide concerned being 24 mm.; such a diameter is quite adequate to yield the 'infinite medium' value of $\varkappa$ at a wave-length of 12·5 mm. After transmission through the water layer, the energy was picked up in a narrow cylindrical wave-guide probe filled with polythene, of dimensions such as to restrict the propagation to that of the H_{11} mode; the probe was driven by a micrometer, so that its location in the water was accurately known.

It is very difficult to maintain liquid water in a markedly supercooled condition, no matter how pure it may be, except when in contact with quite a restricted range of materials, one of which is glass. No success was achieved in the present series of experiments until the wide wave-guide was lined inside with a thoroughly cleaned thin-walled glass tube, and until the probe wave-guide was similarly covered with a thin-walled clean glass sheath. It was established, by making comparative measurements at temperatures above 0° C., that the introduction of these pieces of glass made no difference to the measured absorption coefficient. The temperature of the water was determined by a calibrated thermocouple inserted between the outer wall of the probe wave-guide and its glass sheath. The observed values of $\varkappa$ over the temperature range $-$ 7° C. to 46° C. are shown in the accompanying graph.



Absorption coefficient of pure water as a function of temperature and for a wave-length of 12·5 mm.

It will be seen that the absorption coefficient varies in a completely continuous manner as the temperature of the water passes through 0° C. The absorption mechanism in water, which is a pure polar liquid, is that associated with dipolar dispersion, and it has been shown[1] that a close relation exists between the relaxation time of the polar water molecule and the viscosity of water, though not quite of the simple form originally suggested by Debye[2]. Since it is known[3] that the viscosity varies continuously through 0° C. down to $-$ 9·6° C., it is therefore not surprising that the absorption coefficient exhibits similar characteristics. A detailed description of this work will be published elsewhere later, together with an account of similar measurements at other wave-lengths.

The work described above was carried out as part of the programme of the Radio Research Board. This paper is published by permission of the Department of Scientific and Industrial Research.

A Photo-electric Wool Staplemeter

The possibility of constructing a photo-electric apparatus capable of measuring the variations in fibre-length and diameter, and hence of 'tippiness' and 'break' in wool staples, has been exercising the mind of one of us (H. G.) for some time past, but only after reading a recent paper by Lord[1] were steps taken towards its realization. An experimental model, constructed by the other (R. E. B.), was ready in December 1947. In this model, the wool staple, after it has been prepared as described below, is laid lengthwise under a sheet of glass on an optically black tray (Fig. 1). The tray is capable of moving between two guides along the floor of a light-tight compartment of the apparatus. A 100-watt pearl lamp illuminates a narrow rectangular slit which is focused by means of a cylindrical lens to produce, on the tray top and at right-angles to its motion, a narrow rectangular light image approximately ⅛ in. wide and 3 in. long. The scattered light from the wool is measured by means of a photo-cell which is located directly above the light image. This cell is connected to a direct-current amplifier[2] the output of which is noted on a 0–50 micro-ammeter.

The meter reading (after the zero adjustment operation has been completed) is approximately proportional to the intensity of the light falling upon the cathode of the photo-cell and is thus dependent upon the light scattered by the wool fibres. This in turn is proportional to the number of fibres, their cross-section and, to a minor degree, the nature of the scattering surface.

The aim of the preliminary investigation, on which this account is based, was to ascertain the relationship between the photo-electric reading in microamperes and the number of fibres counted at the level at which each of the readings was taken. For this purpose twenty-eight wool samples of the same count

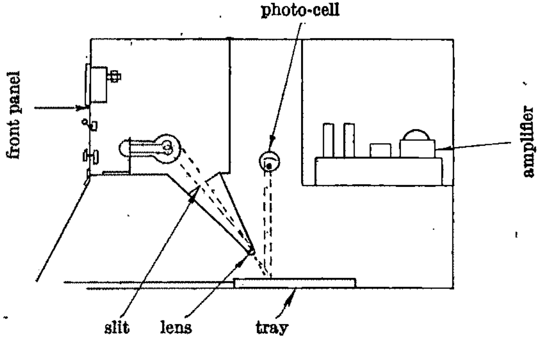

Fig. 1. General arrangement

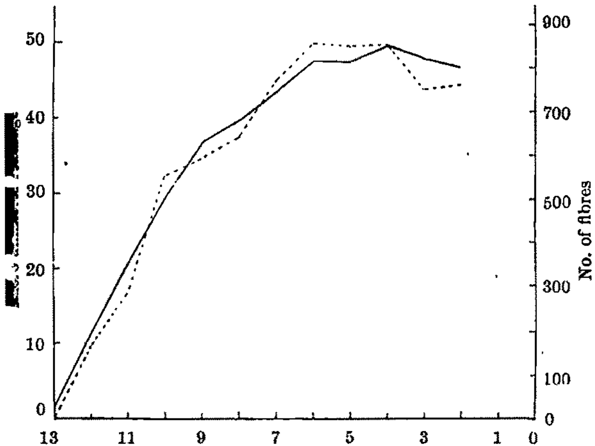

Fig. 2. Full line, number of fibres; broken line, micro-ammeter readings

50's) and practically free of hairiness[3] were taken from New Zealand Romney Marsh unshorn (that is, not shorn as lambs) hoggets[4]. The following testing procedure has been adopted: a small sub-sample is pulled from the staple, secured in a clip at the base of the staple, and washed in benzol. When dry, it is spaced on the staplemeter clamp and teased while hanging perpendicularly. It is then transferred to the staplemeter tray, covered with the cover-glass and the micro-ammeter reading recorded at centimetre intervals. For the purpose of counting the fibres, the sub-sample is cut at centimetre intervals to correspond with the points at which the micro-ammeter readings are taken.

The twenty-eight intra-staple correlation coefficients between the micro-ammeter readings and the number of fibres thus computed proved to be statistically highly significant; their values ranged from $r = 0 \cdot 943$ to $r = 0 \cdot 994$ with 9–16 degrees of freedom. Similarly, the correlation coefficient, based on all measurements in twenty-eight samples, $r = 0 \cdot 955$ with 414 degrees of freedom, is very satisfactory, and the coefficient of regression indicates that one unit of the micro-ammeter equals twenty fibres of 50's count on the average.

Fig. 2 gives what probably is a typical example of the relationship between the micro-ammeter readings and number of fibres.

Thanks of one of the writers (H. G.) are due to Dr. E. R. Cooper, director of the Dominion Physical Laboratory, for lending the experimental model for the duration of the experiment, and to Mr. E. A. Clarke, head of the Sheep and Wool Department, Massey Agricultural College, for encouragement and helpful advice; the other writer (R. E. B.) wishes to acknowledge helpful suggestions from Dr. A. G. Bogle, of the Dominion Physical Laboratory.

Drug-Resistance Shown by Trypanosomes Following 'Antrycide' Treatment

THE control of bovine trypanosomiasis by chemotherapy has recently received a welcome stimulus owing to the discovery of the trypanocidal properties of the new drug 'Antrycide'. The original investigators (Curd and Davy, 1949 [1]) have shown its curative and prophylactic action in experimental animals against several species of trypanosomes infecting man and cattle, and at Entebbe, Uganda, we have shown[2] that the soluble sulphate salt of 'Antrycide', in doses of 3–5 mgm. per kilo, cured *Trypanosoma simiæ* infections in pigs. One pig, however, infected with *T. simiæ* and dosed with the relatively insoluble chloride salt at 2 mgm. per kilo, relapsed. A second immediate treatment with 5 mgm. per kilo 'Antrycide' sulphate failed to cure this pig, and the relapse strain was considered, therefore, to have developed drug-resistance in this short time.

This question of drug-resistance will require careful investigation in the case of *Trypanosoma congolense* and *Trypanosoma vivax* infections in cattle. Experiments at Entebbe indicate that strains of trypanosomes found in re-infected animals after the first treatment with 'Antrycide' may have considerable resistance to further treatment. This is illustrated by an experiment in which ten cattle were dosed with 2 gm. each of 'Antrycide' sulphate and were then exposed to trypanosome infection in a *Glossina pallidipes* area. Only one was alive six months later, and a strain of *T. congolense* collected from this animal and sub-inoculated into a non-infected calf at the laboratory resisted treatment with 5 mgm. per kilo 'Antrycide' sulphate; and when six mice were infected with the same strain and treated with 10 mgm. per kilo 'Antrycide' sulphate, two of them relapsed 52 days later. A field strain collected in the same area from an untreated ox was cured with 'Antrycide' sulphate at 0·5 mgm. ger kilo.

In some cases, animals re-infected some months after treatment with 'Antrycide' and re-treated with curative doses of 'Antrycide' sulphate have developed cryptic but nevertheless fatal infections. Should such cryptic infections or prolonged latent infections prove to occur frequently after 'Antrycide' treatment, an accurate estimation of the true duration of the prophylactic effect will be difficult.

We have some evidence to show that *T. vivax* also quickly develops an appreciable degree of drug-resistance after treatment with 'Antrycide'.

Treatment with 1 mgm. per kilo dimidium bromide (phenanthridinium 1553) of relapse or re-infected strains of *T. congolense* following 'Antrycide' treatment has been unsuccessful, and it appears that strains resistant to 'Antrycide' are also resistant to curative doses of dimidium bromide.

In animals which have relapsed or become re-infected after treatment with 'Antrycide', a dose of 5 mgm. per kilo will not ensure sterilization of the infection in every case and may favour the development of drug-resistance, while a dose in excess of 10 mgm. per kilo can be toxic. The toxic symptoms sometimes develop quickly, the animal losing consciousness and dying two to six hours after treatment; in other cases a severe gastro-enteritis develops forty-eight hours after treatment, and death occurs between the sixth and twelfth days.

Drug resistance may be due to the elimination of the more susceptible trypanosomes with the consequent development over several generations of resistant strains, or possibly the drug may favour the development of resistant mutant strains. In either case, the early treatment of relapsed or re-infected cases before any marked change in the trypanosomes can be produced is obviously more likely to be successful. The limited experience we have had at Entebbe does support this contention. Repeated treatments in the field three to four times a year will, however, require careful planning, may prove expensive, and the ultimate success of such a procedure in tsetse areas still awaits proof.

Influence of Streptomycin and Mineral Salts in the Action of Ribonuclease

The influence of streptomycin sulphate (Pfizer) and chloride (Ayerst) on the action of crystalline ribonuclease, prepared according to Kunitz[1], has been tested under the conditions indicated by Kunitz himself for the dosage of the activity of this enzyme.

The antibiotic was added to the fermentative system in the quantities required to attain concentrations decreasing from 1 : 1,000 to 1 : 10,000,000. As a substrate, a highly purified ribonucleic acid was used, which could be wholly precipitated by means of uranyl acetate in trichloracetic acid solution. Contrary to the observations of other authors[2], who have, in any event, worked under different conditions and employed different methods, inhibition of the action of the ribonuclease through the streptomycin was not observed.

Under the conditions in which our experiments took place, an increase of the activity of the enzyme was obtained, which at a 1 : 1,000 concentration of streptomycin reached an average increase of 50–60 per cent of the initial value. At a concentration of 1 : 10,000, the increase was 20 per cent on the average; and no change in comparison with the control could be observed by further dilution.

In order to investigate whether there is a relation between the power of streptomycin to precipitate the nucleic acids and its influence on the activity of the ribonuclease, the effect of soluble salts on such a precipitate was studied[3,4,5].

Sodium chloride and magnesium sulphate were used, and it was found that even in the absence of streptomycin, sodium chloride increases the effect of ribonuclease by about 60–65 per cent at a concentration of 0·45 per cent in the fermentative system. The effect resulting from the association of sodium chloride and streptomycin does not correspond to the addition of the effects of each substance taken separately. In fact, in a system containing streptomycin at a concentration of 1 : 1,000 and sodium chloride at a concentration of 0·45 per cent, an average increase of only 75 per cent is obtained.

Magnesium sulphate also shows an activating action on ribonuclease, greater than that of sodium chloride at the same concentration. Indeed, it produces an increase of 50–60 per cent at a concentration of 0·1 per cent, whereas at such a concentration sodium chloride is wholly ineffective.

The association of magnesium sulphate and stre mycin does not produce an effect correspondin the addition of both actions.

The effect of other substances on the actio ribonuclease is being studied. The results of studies will be published later, together with a tailed description of the method employed.

I wish to thank Miss Anna Spelta and Miss En Berti for their co-operation.

Origin of Hyaluronidase in the Rat Te

Duran-Reynals[1] demonstrated that mammal testes contained a factor—the spreading facto which was capable of increasing the permeability the connective tissue. This observation has b confirmed by other investigators, and the factor been identified as the enzyme hyaluronidase. Spr *et al.*[2] showed that hyaluronidase was present testes from adult rats, but not in testes from fantile or cryptorchid rats. In their opinion, formation of hyaluronidase depended on compl spermatogenesis.

Eichenberger[3], Kurzrok *et al.*[4], and Werthesser *al.*[5] demonstrated a certain relation between content of hyaluronidase of human semen the number of spermatozoa, but were una to demonstrate any complete proportionality. It not ascertained at which stage of spermatogen the hyaluronidase was formed.

In order to find out at which time the hyaluronid is formed in the testis, I have examined testes fr rats of different ages, and the amount of hyaluronid has been compared with the histological pictu The testicular tissue was extracted with water, to ten times its own weight; the extraction t place at 4° C. and lasted twenty-four hours. Th the amount of hyaluronidase was determined by viscosimetric technique described by Riisfeldt[6], wh is a slight modification of the method of Hale[7]. T results are shown in the accompanying table.

No. of rat	Weight of one testis (mgm.)	Histological examination	Hyaluronidas content per gm. wet tissu (relative value
28	85	Only spermatogonia	0
29	83		
38	90	Spermatogonia and few spermatocytes	(+)
39	95		
45	160	Spermatogonia, many spermatocytes and ÷ spermatozoa	++
81	385	Spermatogonia, spermatocytes and ÷ spermatozoa	+++
27	520	Spermatogonia, spermatocytes, few spermatozoa	++++
106	1250	Adult rat with normal spermatogenesis	++++

It is thus possible to demonstrate considerable amounts of hyaluronidase in rat testes before spermatogenesis is complete. In No. 28, which contained spermatogonia only, it was impossible to demonstrate the presence of hyaluronidase in spite of the fact that a very concentrated testicular extract was used in the determination. In Nos. 28 and 29, owing to the small quantity of testicular tissue, the determination of hyaluronidase was performed on all four testes at the same time, after tissue for the histological examination had been removed. The same applies to Nos. 38 and 39, where it was found that the formation of spermatocytes had commenced, and here it was possible to show the presence of hyaluronidase, although only in a very slight amount. Not until in No. 45, where there were many spermatocytes, was it possible to show the presence of larger amounts of hyaluronidase. Also in No. 81, where the number of spermatocytes was still larger, considerable amounts of hyaluronidase could be demonstrated in spite of the fact that the spermatocytes had not yet been transformed into mature spermatozoa.

In No. 27 spermatogenesis was complete; but only a few spermatozoa were found at the histological examination. The largest amount of hyaluronidase was found here; but incidentally not much more than in No. 81, where the formation of mature spermatozoa had not begun.

Thus the content of hyaluronidase seems to increase with the number of spermatocytes.

In a large number of rats it was possible to show that the formation of hyaluronidase was very pronounced in testes before the spontaneous descent had occurred.

According to the investigations presented here, there seems to be no doubt that the formation of hyaluronidase in rats occurs at an early stage of the spermatogenesis, namely, before there are any mature spermatozoa, and that it is the spermatocytes that are responsible for the formation of hyaluronidase.

A detailed account of the present work will be published elsewhere.

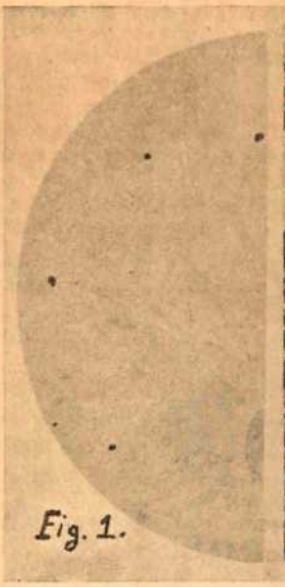
The Histochemical Test for Alkaline Phosphatase

WE should like to direct attention to the occurrence of a phenomenon of diffusion in the histochemical technique for the demonstration of alkaline phosphatase which makes precise localization of the enzyme difficult and is apt to produce errors in interpretation. With regard to such possible diffusion, two opposing views have been taken. Danielli[1], on the basis of specially designed experiments similar to, but not identical with, some of those to be reported here, has denied such diffusion (that is, of the reaction product) and declared the method as very reliable with regard to the localization of the enzyme. Lison[2], on the other hand, takes—at least with certain tissues—the occurrence of diffusion (that is, of enzyme) for granted and makes bad histological fixation responsible for it. There is abundant evidence in the literature in the form of photomicrographs, tabulated records, and descriptions of positive reactions given by cell constituents, especially nuclei, in the vicinity of regions of high phosphatase activity which makes the existence of diffusion as a complicating factor very likely; yet positive proof has so far been wanting. The following experiments seem to furnish such proof.



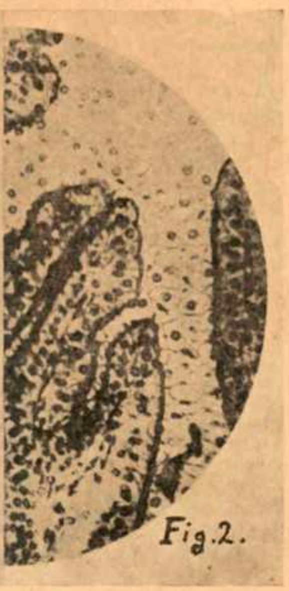


Fig. 1. Portion of guinea pig liver. Alkaline phosphatase reaction, 24-hr. incubation. Only a few phosphatase-positive cells in sinuses. Liver parenchyme negative. × 190

Fig. 2. Part of rabbit duodenum superimposed on guinea pig liver. Alkaline phosphatase reaction, 6-hr. incubation. Note: 'positive nuclear reaction' of the underlying liver cells with a decreasing gradient towards the top right, that is, away from the villi. × 190

(1) Frozen or paraffin sections of alcohol-fixed portions of small intestine or renal cortex (material with high phosphatase content) were superimposed on ready-mounted paraffin sections of alcohol-fixed guinea pig liver (material which for the present purpose can be regarded as phosphatase-negative[3] (Fig. 1)). Gomori's technique with and without added magnesium ions to the substrate mixture (sodium glycero-phosphate, pH 9·2–9·5) and with varying incubation periods was then applied. As a result, the nuclei of the underlying liver cells gave, sometimes as early as after $\frac{1}{2}$-hr. incubation, usually somewhat later, a positive reaction in regions that lay close to centres of high phosphatase activity of the superimposed section, with a gradient of diminishing 'staining' intensity away from these centres (Fig. 2). The degree of this 'positive nuclear reaction' in the underlying tissue is a function of the amount of active phosphatase in the overlying section and of the time of incubation.

(2) That diffusion also occurs within a section from foci of high phosphatase activity could be shown by excising a peripheral wedge, containing portions of Brunner's glands and adjacent muscle coats from a paraffin section of alcohol-fixed rabbit duodenum (previously tested and found to have a very high phosphatase activity), and treating this excised material simultaneously with, but on a different slide

from, the donor section according to Gomori's method. Whereas the latter—after 24-hr. incubation or even earlier—showed a widespread nuclear reaction including all the acini of Brunner's glands and most of the outer muscular coats, the excised wedge was found negative even after 72-hr. incubation.

There was no evidence of bad histological fixation. The diffusion occurs during the incubation period. Its duration is therefore of paramount importance and has to be carefully controlled for each tissue under investigation, for which purpose diffusion tests employing guinea pig liver as underlying material can be recommended.

Details of these and other experiments and a discussion of their implications will appear in the *Journal of Anatomy.*

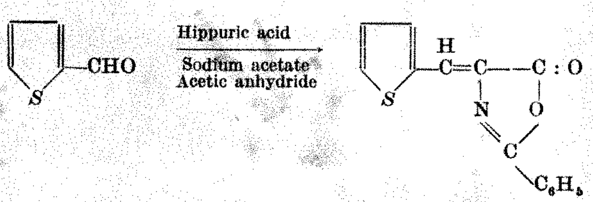
Syntheses of New Azlactones from Thiophene Aldehydes

In view of the availability of thiophene-2-aldehyde, 3-methylthiophene-2-aldehyde, 5-methylthiophene-2-aldehyde, 5-ethylthiophene-2-aldehyde, 5-propylthiophene-2-aldehyde, and 5-chlorothiophene-2-aldehyde[1], it was decided to prepare their azlactones, since these compounds serve as useful derivatives and intermediates for further syntheses.

The formation of these compounds proceeds as follows:



Using the procedure of Kropp and Decker[2], the compounds in the accompanying list were prepared.

Compound	Yield (%)	m.p. (° C.)	Analyses Calculated (%)	Analyses Found (%)
2-phenyl-4(2-thenal) 5-oxazolone[3]	68	174·5–175·5	C 65·88 H 3·53 N 5·49	C 66·1 H 3·66 N 5·69
2-phenyl-4(2-thenal 3-methyl)5-oxazolone	60	151–152	C 66·91 H 4·09 N 5·20	C 66·87 H 4·07 N 5·51
2-phenyl-4(2-thenal 5-methyl)5-oxazolone	58	152–153	C 66·91 H 4·09 N 5·20	C 67·00 H 3·94 N 5·40
2-phenyl-4(2-thenal 5-propyl)5-oxazolone	60	97–98·5	C 68·69 H 5·05 N 4·71	C 68·80 H 5·28 N 4·90
2-phenyl-4(2-thenal 5-ethyl)5-oxazolone	60	107·5–109	C 67·84 H 4·59 N 4·94	C 68·02 H 4·48 N 4·94
2-phenyl-4(2-thenal 5-chloro)5-oxazolone	61	182·5–183·5	C 58·03 H 2·76 N 4·83	C 58·40 H 2·74 N 5·19

All melting points are uncorrected.

Our studies include an extension of the reactions of unsaturated azlactones to the thiophene series as well as other syntheses of the rhodanine and hydantoin derivatives of thiophene aldehydes.

This investigation was carried out with the aid of a grant from the Office of Naval Research, and full details of it will be presented in due course elsewhere.

Thermal Decomposition of Hydrogen Peroxide in the Vapour Phase

Baker and Ouellet[1] reported that when they boiled 98 per cent hydrogen peroxide solution at 100° C. and passed the vapour at pressures varying between 3 and 18 cm. of mercury through a wide 'Pyrex' tube heated to 335° C., they got no explosion even when they passed an electric discharge along the tube or caused a piece of cotton to burn in the gas. We find that, in a 3-cm. diameter 'Pyrex' tube at 100° C., thermal decomposition flames and explosions are very readily initiated by a hot wire or a spark when the pressure is about 2 cm. of mercury or higher. At atmospheric pressure the explosion is very violent and is initiated by catalytic spots on imperfectly cleaned glass. The minimum temperature to which a wire must be heated to cause immediate ignition of the gas at atmospheric pressure has been roughly determined to be about 600° C. Thus, hydrogen peroxide seems similar in its behaviour in the vapour phase to the di-alkyl peroxides with which Harris[2] obtained thermal explosions. These compounds, unlike hydrogen peroxide, decompose entirely homogeneously below 170° C., the temperature around which the explosions occur. The results of the latest workers with hydrogen peroxide are not in complete agreement on this point. Giguère[3] reports no slow thermal decomposition at temperatures as high as 420° C.; but Mackenzie and Ritchie[4] are of the opinion that their results may indicate an appreciable gas-phase reaction in the upper part of their temperature range (namely, 82–137° C.).

It has been found possible to stabilize the flame at pressures as low as 4 cm. of mercury on a jet. It is then clearly visible in a darkened room. An interesting effect is produced by igniting the vapour above rapidly boiling liquid. The flame comes to rest on the surface, and the liquid then boils away steadily but much more quickly than before, going straight to the decomposition products. When resting on the liquid, the flame becomes less easily visible, probably because its temperature is lowered by the presence of a fine spray of the liquid.

The vapour explosion shows no tendency to pass to the liquid phase even when that is 99·8 per cent hydrogen peroxide boiling at atmospheric pressure (*c.* 150° C.). It is clear that most of the explosions said to result from heating concentrated hydrogen peroxide solutions to 150° C. occur in the vapour, and not the liquid phase as is generally implied[5].

It is proposed to continue to study this interesting reaction in greater detail, and to publish a full report elsewhere.

Vibrations of an Infinitely Long Chain of CH_2-Groups and the Infra-red Spectrum of Polythene

THE vibrations of an infinitely long chain of CH_2-groups have been calculated using a valence and angle force potential. It is assumed that the carbon atoms form a zigzag line in the x,y-plane, from which the two C—H linkages branch off symmetrically with respect to this plane, with the x-axis as molecular axis. This array can be considered as a crystal lattice the elementary cell of which consists of two CH_2-groups (six particles in the cell) resulting in eighteen vibrations of the elementary cell. The potential function V has the form:

$$2V = f_C \sum_i l_i^2 + f_H \sum_i (l_i'^2 + l_i''^2) + b^2\varphi_H \sum_i \beta_i^2 +$$
$$a^2\varphi_C \sum_i \lambda_i^2 + ab\,\varphi_{CH}\left\{\sum_i(\delta_i'^2 + \delta_i''^2) + \sum_i(\varepsilon_i'^2 + \varepsilon_i''^2)\right\} +$$
$$2\,ab \sin\frac{\theta}{2}\,\tau \sum_i \Psi_i^2.$$
$$(\lambda_i = \beta_i - \delta_i' - \delta_i'' + \varepsilon_i' + \varepsilon_i''),$$

where l_i is stretching of $C_i—C_{i+1}$ linkages; l_i' and l_i'' are stretching of two C—H linkages attached to C_i; λ_i is change of the angle $C_{i-1}—C_i—C_{i+1}$; β_i is change of the angle $H_i'—C_i—H_i''$; δ_i', δ_i'' are changes of the angle $C_{i-1}—C_i—H_i$; ε_i' and ε_i'' are changes of the angle $H_i—C_i—C_{i+1}$; Ψ_i is angle of twist of C—C linkages produced by a rotation of the two CH_2-groups at the ends of the bond around it; a is the equilibrium distance of the carbon atoms, b of the C—H linkages and θ the tetrahedral angle; f_C, f_H, etc., are the force constants associated with these movements.

The vibrations can be split up into two groups, symmetric and antisymmetric with respect to the x, y-plane. There are five frequency branches in the symmetric group and four branches in the antisymmetric group. The eighteen vibrations (corresponding to the phase differences 0 and π) have been evaluated as functions of the force constants and interatomic distances, and the dipole moments associated with them calculated on the assumption that only the C—H linkages carry a dipole moment. Five frequencies turn out to be zero (improper vibrations), and of the remaining thirteen only five are infra-red active. The inactivity of the other vibrations is due to the inner symmetry of the elementary cell (symmetry group S_2(i)).

An attempt has been made to fit these vibrations to the observed infra-red spectrum of polythene[1] (molecular weight 13,000); the results of the calculations are compared in the accompanying table with Thompson and Torkington's[1] and Fox and Martin's[2] observations.

Infra-red spectrum of C_nH_{2n}

Symmetry class	Frequencies in wave numbers		Relative intensities	
	Calc.	Obs.	Calc.	Obs.
A_g	ν_2 1090 cm.$^{-1}$	1080 cm.$^{-1}$ [1]	0	3·5
	ν_3 2880	2853 [2]	0	0·9
	ν_4 1560	—	0	—
	ν_5 890	890 [1]	0	2·0
	ν_6 1617	1640 [1]	0	1·0
A_u	ν_8 717	725 [1]	100 M_z	100 σ [3,4]
	ν_9 2960	2960 [2]	0·7 M_z	0·6
B_g	ν_{12} 1710	1710 [1]	0	0·9
	ν_{13} 1490	1380 ? [1]	0	16 π [4]
	ν_{14} 2980	—	0	—
B_u	ν_{16} 1307	1310 [1]	10 M_x	0·8
	ν_{17} 2884	2925 [2]	1·7 M_y	0·5
	ν_{18} 1460	1460 [1]	65 M_y	27 σ [3,4]

The observed intensities refer to the absorption coefficient at maximum absorption; the calculated intensities are proportional to $n^2e_H^2$, where n is the number of CH_2-groups in the molecule and e_H the effective charge on the CH-dipole. M_x, M_y and M_z are the non-vanishing components of the dipole moment; the observed polarization is indicated by π and σ. π and σ mean that the intensity of the band is stronger when the incident electric vector is parallel or perpendicular to the molecular axis (x-axis). The inactive bands are, with two exceptions, weakly active, possibly on account of the two CH_3-groups at the ends of the molecule. Besides, any folding of the chain would destroy the $S_2(i)$ symmetry, that is, alter the selection rules. The spectra of cracked polythenes observed by Thompson and Torkington[1] seem to show that the case of molecular weight 7100 ($n \sim 500$) must still be treated as a finite molecule, whereas the periodic structure is fully established for a molecular weight of 13,000 ($n \sim 900$).

It is proposed to extend this treatment to more complicated polymers. A detailed report of the calculations will be published shortly.

Metallic Oxides as Barrier Treatments for Prevention of Attack by Light on Cellulose

ALTHOUGH the literature contains evidence of sporadic attempts to investigate various types of barrier treatments on cellulose for the prevention of attack by light[1,2,3], no systematic work would appear to have been carried out to date on the subject. The evidence is often conflicting, as in the case of iron compounds[1,3], and in any event the mechanism of protective action of such diverse barriers as have been studied is not clear. In the course of a wider investigation on the elucidation of the mechanism of attack by light on cellulose, which is in progress in this Laboratory, it was considered of immediate practical importance to study on systematic lines the influence of certain metallic oxides deposited on cotton fabric in protecting the latter against actinic attack. While the details of the technique of investigation and the results obtained, particularly on the chemical aspect of protection/deterioration of cellulose, are reserved for a future publication, it is the object of the present note to direct attention to the remarkable effect of manganese (as oxide) in inhibiting actinic deterioration.

The metals investigated were chromium, copper, iron, manganese, tin, titanium and aluminium. Three different concentrations of the metals, approximately 0·05, 0·5 and 1 per cent on the weight of fabric, were studied. Dosootie, a fabric of Indian tentage, was used. The metals were deposited as their oxides on the fabric by a double-bath process involving initial treatment in a soluble salt solution and subsequent decomposition with aqueous solution of alkali. The treated fabrics and untreated control pieces were exposed during hours of sunshine at Kanpur (lat. 26° 26′ N., long. 80° 22′ E.) for a total period of 2,400 hours. Samples were drawn according to a randomized plan initially and at intervals of 400 hours. Bursting-strength determinations were carried out at each sampling.

The results showed that manganese (0·56 and 1·3 per cent) on fabrics retards in a remarkable manner the course of actinic degradation; there is possibly a critical concentration of manganese above which only the protective effect is apparent. Although iron and aluminium in the higher concentrations (0·84 and 0·45 per cent respectively) show some protective effect in the very early stages of exposure, they are not useful. Fabrics containing chromium in the higher concentrations (0·8 per cent) generally follow the pattern of the control in the rate of degradation. Copper, tin and titanium accelerate degradation, the effect being most marked in the case of copper and titanium.

While the result with copper is not surprising, the behaviour of manganese in inhibiting actinic degradation has considerable practical possibilities. Confirmatory experiments on this are in progress.

Preparation of Ferric Succinate Jellies

It is well known that a neutral solution of succinic acid gives a brownish-red precipitate of ferric succinate with a ferric chloride solution. Handl[1] obtained brownish-red crystals of ferric succinate by treating a ferric chloride solution with a solution of sodium succinate. We have now succeeded in preparing ferric succinate jellies.

The jellies have been obtained by the metathetical reactions between ferric chloride and sodium succinate. A ferric chloride solution containing 17·54 gm. of ferric oxide per litre and a 5 per cent solution of sodium succinate were found to give the best jellies. To 4 c.c. of the ferric chloride solution were added different amounts of the sodium succinate solution. The total volume was kept at 6 c.c. in each case. The mixtures were shaken for about thirty seconds and then allowed to stand in a bath maintained at 25° C. The influence of the varying amounts of sodium succinate on the time of setting of the jellies was recorded.

Amount of sodium succinate (c.c.)	Time of setting (hr.)
2·0	1
1·9	2
1·8	4
1·7	6
1·6	9
1·4	15
1·2	24
1·0	36

These jellies, like the jellies of ferric phosphate and ferric arsenate investigated by Prakash[2], and of thorium borate investigated by Mushran[3], are transparent, firm and perfectly stable. It is, however, interesting to note that whereas the other transparent jellies of ferric salts have been obtained by the dialysis of their sols and subsequent coagulation with suitable electrolytes, ferric succinate is the only jelly of iron so far known which has been obtained in a perfectly transparent state by the metathetical process. These jellies do not exhibit any syneresis and maintain their transparency even when kept for a long time. They set more readily at higher temperatures than at low, but lose their uniformity of texture and become opaque when allowed to set at high temperatures.

Genetical Differences in Taste Sensitivity to Phenylthiourea and to Anti-thyroid Substances

Fox[1] first observed that people differed in their ability to taste phenylthiourea, and it was found (Blakeslee and Salmon[2], Blakeslee[3], Snyder[4,5]) that these differences were genetically determined. The distribution of taste thresholds to this substance in all populations so far studied has been found to be bimodal. Familial investigations indicate that the two classes of individuals, 'tasters' and 'non-tasters', that is, those relatively sensitive and those relatively insensitive to phenylthiourea, differ in respect of a single gene pair, the 'tasters' being homozygous or heterozygous for the dominant allele, the 'non-tasters' homozygous for the recessive allele. Between one quarter and one third of all individuals tested in various populations appear to fall into the recessive class. Fisher, Huxley and Ford[6] have described observations which suggest that similar differences may exist among anthropoid apes. They have pointed out that this implies the existence of a stable, balanced polymorphism, and that, for such a system to occur, the heterozygotes should have had some selective advantage over the two types of homozygotes.

The taste sensitivity to phenylthiourea has been found to show only slight correlation or no correlation at all with taste sensitivity to some other bitter substances, such as quinine[7,8,9], strychnine[7], picric acid[7,9] and diphenylguanidine[10]. On the other hand, Fox[1] observed that 'non-tasters' for phenylthiourea appeared also to be insensitive to several closely related substances, such as *para*-ethoxyphenylthiocarbamide, symmetrical diphenylthiocarbamide, dibenzylthiocarbamide and dicrotylthiocarbamide, whereas 'tasters' for phenylthiourea were sensitive to them. In this work he used only the powder for testing purposes, and did not determine threshold values. He was not able to detect any differences by this method for one closely related substance, thiourea, which he found had a "nauseating taste to both tasters and non-tasters". Riddell and Wybar[11] found that thiouracil tablets were markedly bitter to phenylthiourea tasters and not bitter to phenylthiourea non-tasters. Hopkins[12] found that 2-mercapto-5,5 dimethyloxazoline, a substance which he extracted from the seeds of a cruciferous weed *Conringia orientalis*, was also bitter to phenylthiourea tasters and not bitter to phenylthiourea non-tasters.

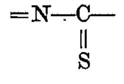
x	<1	1	2	3	4	5	6	7	8	9	10	11	12	13

Thresholds for phenylthiourea and thiourea for 37 individuals. The abscissa denotes threshold values for phenylthiourea in units of $0{\cdot}26 \times (\frac{1}{2})^x$ per cent. The ordinate denotes threshold values for thiourea in units of $(\frac{1}{2})^y$ per cent. The two groups of 'tasters' and 'non-tasters' are the same for both substances.

Recently, we have developed a method of measuring taste thresholds which aims at determining the lowest concentration of the substance at which an individual can accurately discriminate the solution from water. Using this method, we have tested a number of individuals with phenylthiourea, thiourea, symmetrical diphenylthiourea, thioglyoxaline, thiouracil, phenylurea, uracil and urea. We found that there is a high correlation between taste sensitivity for phenylthiourea, symmetrical diphenylthiourea, thiourea, thioglyoxaline and thiouracil. There was no such correlation between sensitivity to these substances and to urea, phenylurea and uracil. (The accompanying table illustrates the relationship found between sensitivity to phenylthiourea and thiourea.) Thus, substances so far tested, to which the genetically distinct types of individuals respond differently, all contain the grouping



$$=\mathrm{N}-\underset{\underset{\displaystyle \mathrm{S}}{\|}}{\mathrm{C}}-$$

This grouping has been found to be of importance in quite another sphere of biological research.

Chesny, Clawson and Webster[13,14] observed the development of goitre and a decrease in metabolic-rate in rabbits fed exclusively on cabbage. This led to experiments with the *iso*-thiocyanates, important chemical constituents of cabbage, and eventually with thiourea and thiouracil. Thiourea and thiouracil have been found to interfere with the function of the thyroid gland and to reduce the formation of thyroxine. Many closely related substances have been examined and found to possess the same anti-thyroid activity in various degrees. Some of these substances, for example, thiouracil, methylthiouracil, propylthiouracil, are now commonly used in the treatment of thyrotoxicosis. Astwood, Bissell and Hughes[15] investigated two hundred and twenty different substances and found that two types of chemical structure were associated with antithyroid activity. The more active class possessed the thiocarbonamide grouping. Among the substances tested and found to have antithyroid activity was 2-mercapto-5,5 dimethyloxalidine.

Differences in taste sensitivity may reflect metabolic differences between individuals with respect to these substances. Such metabolic differences could presumably affect the biological fitness of the three genotypes, and hence perhaps lead to a balanced polymorphism.

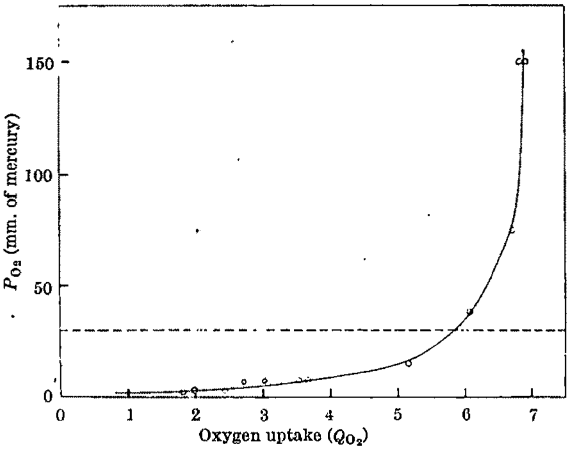
Aerobic Metabolism in Nematode Parasites of the Alimentary Tract

THE conflicting evidence concerning the relative importance of aerobic mechanisms in the metabolism of nematode parasites of the alimentary tract may be summarized by reference to the work of Davey[1], who found that oxygen prolonged the survival of certain intestinal parasites *in vitro*, and that of von Brand and Weise[2], who found oxygen to be absent, or present only in small amounts, in the contents of the alimentary tracts of several host animals.

The problem has been re-examined in the following way: (1) Oxygen tensions in gut fluids close to the mucosa of host animals have been determined in anæsthetized animals with intact alimentary circulations using the electrometric method of Brink and Davies[3]. It was considered that such a method, rather than the analysis of relatively large samples from the intestines of dead animals, would give a more exact indication of the oxygen available to small parasites which probably live close to the mucosa (Porter[4]). (2) The ability of certain nematode parasites of the alimentary tract to utilize oxygen at low partial pressures was next examined. Oxygen uptake was determined by the indirect method of Warburg, using a saline medium in vessels of about 4-ml. capacity. The shaking-rate was adequate, and the oxygen uptake, at a given oxygen tension, was directly proportional to the amount of respiring tissue (50–100 mgm. wet weight).

The parasites examined were *Nippostrongylus muris* from the rat small intestine, *Hæmonchus contortus* from the sheep abomasum and *Nematodirus filicollis* and *N. spathiger* from the sheep small intestine. These parasites were selected because it was thought that they might be small enough to allow oxygen to penetrate to their central tissues even without the aid of a circulatory system, and because they all contain specific hæmoglobins which have low loading tensions, particularly in the case of the sheep parasites (Rogers, unpublished).

Oxygen concentrations close to the mucosa in the small intestine of the rat ('Nembutal' anæsthesia) and in the sheep small intestine and abomasum ('Kemithal' anæsthesia) were determined. Precautions were taken to avoid, as much as possible, the introduction of air into the alimentary tract when electrodes were inserted. In the region of the intestine of the rat where *Nippostrongylus muris* was found, the oxygen tension varied from 19 to 30 (average 24) mm. of mercury in eight animals. Only two sheep were examined; but measurements were taken at four points along the intestine of each animal. Oxygen tensions, as in the rat, were generally higher nearer the pylorus and varied from 12 to 4 (average 6·5) mm. of mercury. The regions normally occupied by the *Nematodirus* spp. showed the lower range of oxygen concentrations. Oxygen tensions on the abomasal mucosa appeared to be higher than in the sheep intestine, but as the technique for handling the abomasum was not satisfactory, these results can only be accepted with reserve.



Oxygen uptake of *Nippostrongylus muris* at different partial pressures of oxygen. The broken line indicates the upper limit of the oxygen concentrations found in the small intestine of the rat host in the region normally inhabited by the parasites

The oxygen consumption of the parasites was found to vary with the oxygen tensions. Results obtained with *Nippostrongylus muris* are shown in the accompanying graph. When the results were treated according to the relationship:

$$A = \frac{P}{K_1 + K_2 P},$$

where A represents the oxygen uptake (ml./hr./gm. dry wt.), P represents the oxygen pressure (mm. of mercury) and K_1 and K_2 are constants, P/A plotted against P gave a straight line with a K_1, the intercept, of 1·2, and a K_2, the slope, of 0·14.

Nematodirus spp. and *Hæmonchus contortus* gave results similar to those obtained with *Nippostrongylus muris*, though both parasites showed less ability to utilize oxygen at low partial pressures. Thus, with oxygen at a pressure of 5 mm. of mercury, *Nippostrongylus muris* showed an oxygen consumption of 40 per cent of the maximum rate, and *Nematodirus* spp. and *Hæmonchus contortus* respired at 25 and 12 per cent of their maximum rates respectively. The results indicate that *in vivo* oxygen tensions may be such that the respiratory-rate may reach 80 per cent of the maximum *in vitro* rate in the case of *Nippostrongylus muris* and 40 per cent in the case of *Nematodirus* spp. *Hæmonchus contortus* probably respires at a relatively lower rate than the intestinal parasites.

It should be emphasized that the above figures are given relative to the maximum rate of oxygen uptake *in vitro*. Even at low oxygen tensions, the parasites make intensely active movements *in vitro* at 37° C.: this activity almost certainly does not occur *in vivo*, in which case the maximum oxygen uptake *in vivo* may be much less than *in vitro*, and respiration *in vivo* may reach a relatively higher rate than the figures given here really indicate.

It may be concluded that aerobic mechanisms play an important part in the metabolism of small nematode parasites of the alimentary tract, particularly in the case of *Nippostrongylus muris* and *Nematodirus* spp.

The results of the work, which was carried out as part of the research programme of the Division of Animal Health and Production, Council for Scientific and Industrial Research, will be published in full elsewhere.

Lymnæa stagnalis as an Intermediate Host of *Fasciola hepatica*

THE possibility of British species of *Lymnæa*, other than *L. truncatula*, acting as vectors of *Fasciola hepatica* has remained a moot point since Thomas[1], in 1883, observed the miracidia to penetrate young specimens of *L. pereger*. The observation of Nöller and Sprehn[2], in 1924, added to the uncertainty, when by dissection of a young specimen of *L. stagnalis* they actually secured cercariæ that were sufficiently far developed to show the lateral glands. As a result of experiments recently carried out at Weybridge, it can now be stated with certainty that *F. hepatica* is capable of completing its development in *L. stagnalis* with the ultimate emergence of cercariæ, which encyst and are capable of producing fluke infestation in mammals.

The snails used in these experiments were freshly hatched second-generation laboratory-reared specimens, maintained under conditions that would exclude all possibility of unwanted infection, or the ingress of any other species of snail. They were exosed to massive infestation by the miracidia of . *hepatica*, freshly hatched from laboratory incuated eggs, the technique of snail infection being the ame as that employed at the Laboratory for the fection of *L. truncatula*.

Examination of 101 of the experimental snails howed that 13 had become infected. Ten of these 3 were dissected before the developmental cycle of he fluke had been completed, two died soon after ommencing to shed cercariæ; but from the third, 99 erfect cercariæ emerged, including 86 which left the nail within a 24-hr. period, 113 days after the date f infection. Four of these cercariæ were pipetted nto the mouth of a rabbit, and in six weeks time ne half-grown specimen of *F. hepatica* was recovered om the bile ducts.

Attempts to infect adult specimens of *L. stagnalis* ave so far failed, and it is interesting to note that he report of Nöller and Sprehn[2] of partial success ith that species, and the report of Thomas[1] of artial success with *L. pereger*, also referred to young pecimens. It appears, therefore, that immature pecimens are more susceptible than are adults.

Although of biological interest, this observation ay have little significance from the veterinary point f view on account of the definitely aquatic habit f *L. stagnalis*, which appears to be confined to ermanent water. It shows the possibility, however, f the maintenance of liver-fluke infestation in enironments from which *L. truncatula* is absent, and uggests that immature specimens of yet other species f *Lymnœa* may also serve as vectors. The investigaion of these possibilities is proceeding at Weybridge, nd partial development of the fluke in *L. pereger* nd *L. palustris* has already been observed.

Symptomatology of Virus Diseases Induced in Cacao by '2–4,D' Treatment

DURING the treatment with commercial '2–4,D' mulsions of small blocks of cacao (*Theobroma cacao*) r weeding, in Venezuela, a peculiar phenomenon as observed incidentally. Basal shoots ('chupons') eact to the treatment with distortion and malformaion, then dropping of young leaves. A few scattered eaves developed from buds were wrinkled, more or ess curled up to rolled, hardened and rugose or mooth, and more or less ruffled. The size of leaves as frequently reduced, chiefly as regards width in elation to the length. A number of leaves were ottled or even chlorotic, but also vein-banded or ith red-stained veins; others were healthy and ormal.

The symptomatology is that of one or two or someimes even more virus diseases, in the same tree, as reviously described in Trinidad by Posnette[1], and n the Dominican Republic and Colombia by Ciferri[2]. f course, the next new flush of foliage consisted of ealthy leaves.

The same effect induced by treatments with 2–4,D' has been observed in Italy on the vine (*Vitis vinifera*) by Baldacci and Topi[3], with symptomatology resembling 'courtnoué' or 'roncet'.

Nutritional Requirements of *Drosophila*

SINCE our earlier publication[1], the following additional information has been obtained about the nutritional requirements of *Drosophila melanogaster*. Addition of 25 γ thymine per culture to the basal medium leads to accelerated development, pupæ being formed seven days after egg-laying. This represents a decrease in developmental time of one day at least over controls without thymine. Further acceleration can be obtained by addition of 20 mgm. of a yeast fraction prepared by treating yeast with hot 2 per cent sodium bicarbonate, filtering, rendering slightly acid with hydrochloric acid, and precipitating the fraction with an excess of ethanol. Pupation can then ensue five days after oviposition. That the active fraction is not nucleic acid as supplied commercially is shown by the fact that parallel cultures without the fraction, but containing additional nucleic acid, do not show the same effect.

There is also some evidence that the basal medium as constituted at present may be deficient in some specific amino-acid. This is suggested by the fact that the addition of globin (prepared from hæmoglobin by hydrochloric acid hydrolysis and salting out) gave pupæ of much larger size than those obtained from the normal basal medium. This possibility is now being followed up.

For convenience, the composition of the basal medium as now constituted is given below.

	gm.		gamma
Casein (vitamin-free)	0·06	Aneurin hydrochloride	4
Gelatin (reprecipitated)	0·045	Riboflavine	6
dl-Tryptophane	0·005	Nicotinic acid	12
Ergosterol	0·005	Pyridoxin	12
Cholesterol	0·005	Biotin	0·2
Dextrose	0·1	Calcium-*d*-pantothenate	1500
Agar	0·1	Thymine	25
Yeast nucleic acid	0·0034	Inositol	12
Tatum salt mixture (1936)	0·006	Folic acid Choline chloride	2 1000
Water to 5 ml.		(*p*-amino-benzoic acid)	25

Full details will be published elsewhere.

Pregnancy Test using Male Anura

CONFIRMING the validity of the Galli-Mainini test for pregnancy in the male toad *Bufo arenarum*[1] and referring to the suitability of *B. marinus*[2] and *Rana pipiens*[3], Haines[4] raises the question of the possible suitability of two European species, *B. bufo* and *R. temporaria*. We have demonstrated[5] the suitability of a European frog, *R. esculenta*; and on a theoretical basis we have assumed that the Galli-Mainini test must be common to the Anura (toads and frogs).

Meanwhile, many other species have been successfully employed in America (*B. paracnemis*, *B. crucifer*, *Calyptocephallus gayi*, *Leptodactillus ocellatus*, *Xenopus lævis*, *Odontophrynus*, *B. d'Orbigny*[6], *R. catesbeiana*[7]) and in Europe (*B. vulgaris*, *B. viridis*[8], *B. calamita*[9]).

Fifteen species of toads and frogs having been observed and found suitable, we think that the general hypothesis is largely confirmed. Although it will be practically impossible to establish with certainty that any male toad or frog at any time may be used, there is no special interest in such a theoretical security; for it is always possible to avoid false positive reactions by examination of the animal's urine before the test, and to avoid false negatives by previously testing each animal with urine of a woman known to be pregnant, the tested animal being fit for use after a week. From the latter point of view the testing of one animal from among a uniform batch will usually be sufficient, and the remaining animals can be used immediately.

There is one important difference between different species, namely, the size of the animal. The quantity of urine used should be approximately equal to one tenth of the average weight of the species utilized. No special precautions are necessary as regards the woman's urine; any specimen may be used directly. The activity is conserved at least for a week at room temperature[6]. We have obtained positive results with urine kept for a month in a refrigerator.

There is some doubt on the time convenient for certain results[6]. In a great majority of cases (all in our experience) positive reactions occur within two hours. It can be inferred that in the small percentage of cases of delayed response, the delay would not be greater than a further hour. As a positive reaction at two hours can never become negative at three, we propose to adopt a standard time of about three hours.

University Education in Natural Science

In the leading article in *Nature* of April 30, attention is rightly directed to the high degree of specialization which is now demanded of our science graduates, a degree of specialization which, as is said there, "too often begins", and as I should say because of university scholarship demands, "usually begins", at school.

A re-organisation of university teaching is clearly long overdue, but it is doubtful whether it will be as difficult as that article suggests. Is not the obvious solution that which I put forward at the meeting of the British Association at Brighton last year, namely, that the first science degree for undergraduates should normally be a general science degree ? I say "normally" because there is no reaso why the special honours degree should not be retaine for exceptional cases. But for the ordinary scientifi student, surely a degree in a number of interrelate subjects is what is required. "It gives a student grounding in a variety of subjects and, if it is properl taught, of necessity it shows the interrelationships those subjects, and it does not lead to that completely unintellectual isolation which results so ofte from the special honours degree."

Many people, of course erroneously, consider general degree as something new and somethin inferior ; but it is not. The first part of the Cambridg Natural Sciences Tripos is a general honours degre and it is certainly neither new nor inferior. This the principle on which I have acted for years Manchester. Students who wish to specialize i zoology are normally advised to take a general scienc course. If they then obtain a first-class or a goo second-class, clearly they are fitted for further stud and can be advised to specialize in a postgraduat year. For such an extension of their studies mone is nowadays forthcoming; but it is only reasonab that such an extra year's work should carry with a further degree, and why not a master's degree In Manchester, for such a degree there is no nee for the work to be original research. It can alternatively consist "of an essay on some scientific questio of importance involving criticism or historic research". It is an easy matter for a head of department to interpret this latter alternative so to include whatever degree of specialization he considers necessary at such a level.

Another Little-known History of Botany

In *Nature* of May 7, p. 732, Dr. Jules Brun inquires about the "L. G." who was responsible f the "Précis de l'Histoire de la Botanique", the las of the seventeen volumes of "Le Règne Végétal" by O. Réveil, and others, Paris, 1870–71. The wor in question is not accessible to me ; but I find tha in the catalogue of the Library of the British Museu (Natural History), "L. G." is identified as "L. Gérard' I do not know on what evidence this is based ; have been unable to trace any botanist of this nam who might be the writer of the "Précis". Lou Gérard is too early in date, as he was born in 173 Dr. Brunel's tentative identification with L. Guéri is perhaps more probable ; but it can hold only the work is considered to be within the compass of man who does not seem to have been a botanist This is possible, as the "Précis" describes itself a "Biographique et Bibliographique". As anothe alternative—though a speculative one—I should lik to suggest Lazare Garreau, who was professor a Lille. He was born at Autun in 1812, and publishe papers on physiological botany in the decade 1850–6 He was apparently still living when the second editio of Pritzel's "Thesaurus literaturæ botanicæ" appeared (1872).

EFFECT OF LIGHT ON THE COMBUSTION OF HYDROCARBONS

By Prof. R. G. W. NORRISH, F.R.S., and D. PATNAIK
Department of Physical Chemistry, University of Cambridge

THE slow combustion of hydrocarbons in general takes place by a kinetic process which Semenov[1] described as a chain reaction showing 'degenerate ranching'. According to this conception, the hydrocarbon is first oxidized to a moderately stable intermediate, which is itself oxidized to the final products, amely, carbon monoxide, water, etc. Thus a stationary concentration of the intermediate is built up during the reaction, which reaches a maximum t the time of maximum velocity. According to Semenov's conception, the intermediate is responsible for the starting of new chains by an alternative eaction with oxygen, and a delayed or degenerate branching results.

In the case of methane[4] and ethylene, the intermediate may be identified with formaldehyde, which, as shown by Bone, Haffner and Rance[2] and by Harding and Norrish[3], reaches a maximum concentration at the point of maximum velocity, and which when added to the reactants in the right amount c. 1·0 per cent) completely removes the induction period[4].

The complete scheme derived for the oxidation of methane[6], based on the work of Norrish and Foord on methane[4] and Axford and Norrish[5] on the oxidation of formaldehyde, is as follows:

$$\left.\begin{array}{lll} k_1 & CH_4+O_2 & = CH_2O+H_2O \\ k_2 & H_2CO+O_2 & = H_2CO_2+O \\ k_3 & O+CH_4 & = CH_3+OH \end{array}\right\}\text{Initiation and degenerate branching}$$

$$\left.\begin{array}{lll} k_4 & OH+CH_4 & = CH_3+H_2O \\ k_5 & CH_3+O_2 & = H_2CO+OH \end{array}\right\}\text{Propagation}$$

$$\left.\begin{array}{lll} k_6 & CH_2O+OH & = CO+H_2O+H \\ k_7 & H+O_2+H_2CO & = CO+H_2O+OH \end{array}\right\}\text{Coupled formaldehyde chain*}$$

$$\left.\begin{array}{lll} k_8 & H+O_2+X & =HO_2+X' \\ k_9 & OH+\text{surface} & \rightarrow \text{termination} \end{array}\right\}\text{Termination*}$$

* Reactions (7) and (8) are only formally to be regarded as ternary reactions. The transition complex HO_2 formed with c. 50 k.cal. is unstable unless deactivated (reaction (8)), and reactive only if it encounters a formaldehyde molecule (reaction (7)) before it decomposes, or is deactivated.

In this mechanism, the concentration of formaldehyde, initially zero, grows very slowly at first, during the induction period; and later, as the delayed branching by reaction (2) takes effect, at an ever-increasing rate. But the rate of the oxidation of formaldehyde by reactions (6) and (7), which as is generally agreed depends approximately on the square of its concentration, grows still faster, so that eventually a stationary concentration is reached when its rate of destruction is equal to its rate of production. At this point the velocity of reaction must cease to increase; it settles down to a steady value which finally falls off as the reactants are consumed. Thus we get the familiar S-shaped pressure–time curves. A similar scheme has been derived for the oxidation of ethylene[6].

The steady rate is readily shown to be given by the kinetic equation[6]

$$\frac{-d(\text{Hy})}{dt} = \frac{k_4}{k_6}\left(k_3(\text{Hy})(O_2) + \frac{k_2k_4k_7(\text{Hy})^2(O_2)Pd}{2k_7k_9\sigma + 2k_6k_8P^2d}\right), \quad (1)$$

where (Hy) stands for methane or ethylene, σ the specific surface activity per square cm. for termination by reaction (9), P the total pressure in the system and d the diameter of the reaction vessel. The first term on the right-hand side represents the initiation process, the second the propagation; and the former is generally negligible in comparison with the latter. With methane, the first term in the denominator is large compared with the second, which can be neglected; with ethylene, which oxidizes at a lower temperature, the two terms are of comparable magnitude. This circumstance is responsible for minor differences in their oxidation kinetics.

This general view of the oxidation of methane and ethylene led us to the conclusion that the combustion reaction should be accelerated by light, which is known to dissociate formaldehyde into free radicals, for the degenerate branching reaction (2) would now be augmented by the photochemical process

$$\begin{array}{l} H_2CO + h\nu = H + HCO \\ \qquad\qquad\qquad\qquad\quad \searrow \\ \qquad\qquad\qquad\qquad\quad H + CO \end{array}$$

as a chain-starting mechanism.

If the rate of absorption of light by formaldehyde is given by $k(H_2CO)I$, where I is the incident intensity, the rate equation now becomes modified to

$$\frac{-d\text{Hy}}{dt} = \frac{k_4}{k_6}\left(k_3(\text{Hy})(O_2) + k(\text{Hy})I + \frac{k_2k_4k_7(\text{Hy})^2(O_2)Pd + kk_4k_7(\text{Hy})^2IPd}{2k_7k_9\sigma + 2k_6k_8P^2d}\right). \quad (2)$$

Subtracting the rate in the dark (R_D) from the rate in the light (R_L) we obtain:

$$R_L - R_D = \frac{k_4}{k_6}\left(k(\text{Hy})I + \frac{kk_4k_7(\text{Hy})^2IPd}{2k_7k_9\sigma + 2k_6k_8P^2d}\right); \quad (3)$$

or, keeping σ, I and d constant:

$$R_L - R_D = (\text{Hy}) + \frac{a(\text{Hy})^2P}{b + cP^2}. \quad (4)$$

If, in addition, the total pressure P be kept constant by making up with nitrogen,

$$R_L - R_D = (\text{Hy}) + K(\text{Hy})^2. \quad (5)$$

These predictions have all been confirmed. We used a cylindrical quartz reaction vessel (diameter 3·4 cm., volume 175 c.c.) in a horizontal electric furnace lined with polished aluminium with a quartz window 7 cm. in diameter at one end. A beam of light of high intensity obtained from a high-pressure point-source mercury arc, burning 1 kW., and 'cooled' by passing through 50 cm. of water contained in a tank with parallel quartz sides, was focused into the furnace by means of a searchlight mirror of polished aluminium. The reaction was followed by pressure change, measured by a glass spoon gauge sensitive to a pressure of 0·05 mm. mercury. Fig. 1 shows a typical result.

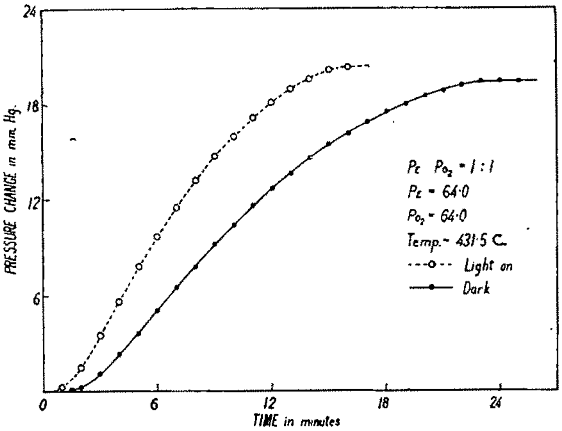

Fig. 1. Effect of light on the slow oxidation of ethylene

When the light beam was passed through a colour filter of 0·5 per cent solution of quinine hydrochloride 7 cm. thick, which cuts out all light of wave-length shorter than 3600 A., the acceleration due to the light was very nearly (90 per cent) suppressed. The formaldehyde absorption spectrum extends from 3750 A. to beyond 2500 A., whereas the spectrum of the lamp extended to 2450 A.; thus the active light lies in the ultra-violet in the region covering the absorption band of formaldehyde. With a more concentrated solution of quinine hydrochloride (2·5 per cent) cutting out all light of less than 4000 A., the effect was completely suppressed.

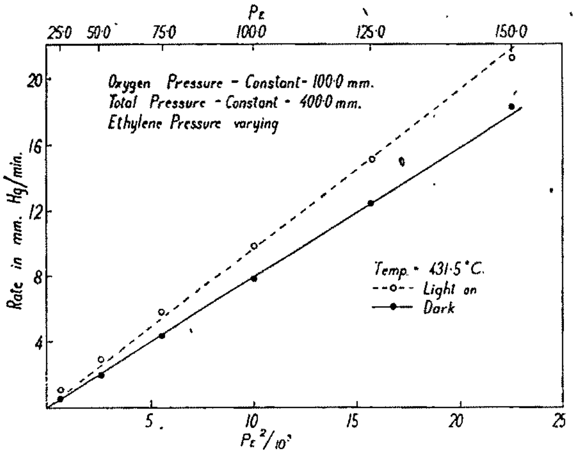

Fig. 2. Effect of light on the slow oxidation of ethylene; ethylene varying, total pressure constant

Figs. 2–5 show that R_L and R_D conform to equations (1) and (2), and that $R_L - R_D$ is independent of (O_2) and approximately proportional to $(Hy)^2$, as is required by equation (4) if the terms in Hy (initiation) are small compared with the terms in Hy^2 (propagation), and if b is large compared to cP^2, as it is in the case of methane. With ethylene we kept the total pressure P constant by adding nitrogen, and therefore $R_L - R_D$ is given by equation (5). Under these conditions, when (Hy) is small the first term in equation (5) preponderates, and $(R_L - R_D)$ is more nearly proportional to (Hy) than $(Hy)^2$. The fact that the experimental points for low (Hy) in Fig. 2 lie above the line is in accord with this.

By working close to the ignition limit with ethylene (C_2H_4 = 225 mm., O_2 = 318, temp. 431° C.) we were readily able to convert a 'slow' dark reaction into an ignition by irradiation; but in this region equation (1) is no longer obeyed owing to the large measure of self-heating as the ignition limit is approached.

These results accord well with the reaction scheme based on formaldehyde outlined above, and confirm the kinetic formulæ previously deduced. They show in effect, that the degenerate branching process can be powerfully affected by light without altering the character of the reaction; and the effect is all the more striking when it is remembered that the initial reactants are completely transparent to the light used.

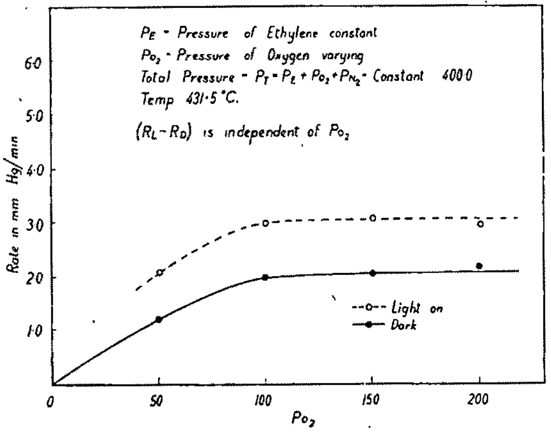

Fig. 3. Effect of light on the slow oxidation of ethylene; oxygen varying, total pressure constant

By using the weaker colour filter (0·5 per cent quinine hydrochloride) it was shown that the effect still persists feebly in light the spectrum of which lies between 3600 A. and 4000 A. Now the predissociation limit of formaldehyde as shown by the threshold of fluorescence is at c. 3000 A.[7], and it must therefore be concluded that some such reactions as

$$H_2CO + h\nu = H_2CO'$$
$$H_2CO' + O_2 = H_2CO_2 + O$$

take place in this region; that is, that reaction (2) is somewhat enhanced by light which excites, but does not split, the formaldehyde molecule.

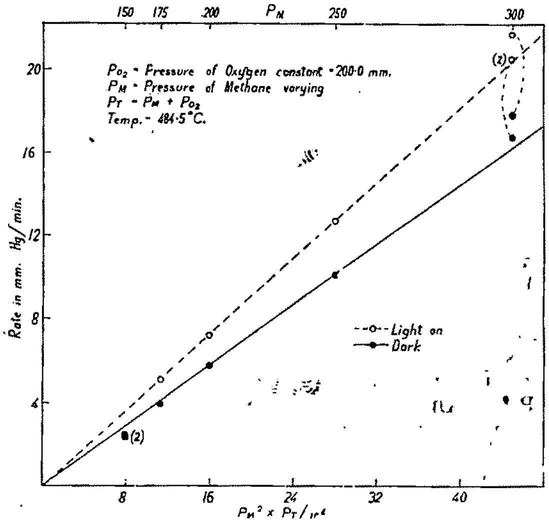

Fig. 4. Effect of light on the slow oxidation of methane; methane varying

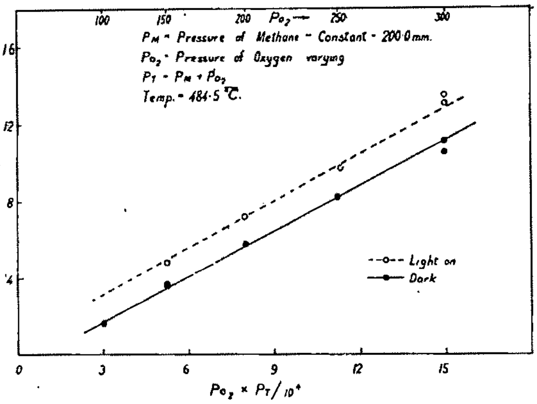

Fig. 5. Effect of light on the slow oxidation of methane; oxygen varying

With heavier hydrocarbons the characteristics of egenerate branching are similarly observed, and we elieve that the heavier aldehydes which are first roduced are similarly responsible for the delayed ranching reaction. On this basis it is possible to uild a self-consistent mechanism of a pattern esembling the simpler reactions treated here[6]. It is gnificant that light readily accelerates the oxidation f butane, and the shapes of the curves in the dark nd in the light suggest different end points; it is robable that the phenomenon will be found to be eneral for hydrocarbons.

This photochemical effect provides a new experiental approach to the study of the reaction kinetics f combustion, and cannot fail to be revealing.

OPTICAL PROPERTIES OF SOLID THIN FILMS

A MOST successful international colloquium on the optical properties of solid thin films was held at Marseille during the week April 19–23 under the auspices of the Centre National de la Recherche Scientifique. Some forty-four physicists attended by nvitation, and, of these, twenty-five contributed papers. There was, of course, a strong contingent from France, including, among others, P. Jacquinot, M. Perrot and P. Rouard. From Great Britain contributions were read by K. M. Greenland, O. S. Heavens, H. Kuhn and S. Tolansky. The United States were represented by B. H. Billings, N. W. Scott, J. Strong and A. F. Turner, the Netherlands by P. van Alphen and B. Blaisse, Italy by M. Ballerini, Switzerland by M. Schaetti and Czechoslovakia by A. Vasicek.

The conference was well organised by Prof. P. Rouard, director of the physical laboratory in the University of Marseille, and was characterized by smooth, efficient working and excellent programme planning. This meeting was held in a provincial university as part of deliberate policy of the Centre National de la Recherche Scientifique, which is arranging a series of international conferences in French provincial university centres. The choice of Marseille for this particular subject of optical properties of thin films was a happy one indeed; for it was there, at the beginning of this century, that Fabry laid the foundation of the very subject under discussion, and it was there, too, under his inspiration that the branch of classical optics associated with the names of Fabry, Buisson, Macé de Lepinay and others was created. Indeed, the visitors all derived considerable pleasure from an exhibition of the original apparatus used by these masters of experimental optics, and were much moved, too, by listening to a recording of the voice of Fabry.

Although a considerable number of papers were read (many contributors read several: for example, the writer contributed five), these all crystallized into four fairly distinct groups: (*a*) determination of optical properties and thickness of thin metal or dielectric films; (*b*) the principles and applications of multiple-beam interferometry; (*c*) preparation of interferometric wave-length filters and discussion of their characteristics; (*d*) improving the optical properties of surfaces by deposition of multiple films with alternate low and high refractive indices.

The conference opened with a session of theoretical papers on the properties of single and multiple thin films, and then plunged into its main work, which consisted of formal papers on experimental aspects connected with the properties and optics of thin films. Occasionally the conference assumed the character of informal discussions on experimental techniques, yet all were agreed that these informal exchanges constituted one of the most valuable features of the whole conference. For it is a fact that success with experimental interferometry, or with those other branches of applied optics which involve surface deposition of films, depends largely upon minor details of personal techniques which are not easily publishable, and are, indeed, often even difficult to describe. For example, a most lively discussion ensued simply on the question of the best method of cleaning a glass surface which is to accept a film by deposition by vacuum evaporation. There were perhaps ten speakers, with the inevitable result that perhaps ten distinctly different techniques were described; but all had one thing in common, namely, final cleaning by ions with a gas discharge. It appears that any reasonable method of cleaning is satisfactory provided the glow discharge is the final cleansing agent.

Many striking and novel optical results were described, and it is anticipated that all the papers contributed will be published together in some form. Such a collection will make a notable contribution to a subject rapidly becoming of considerable importance to technical optics, particularly those fields concerned with either reduction or enhancement of reflectivities of surfaces. The conference was an unqualified scientific success and equally successful socially, thanks largely to Prof. Rouard. The visitors will long remember the magnificent hospitality of their French colleagues. A visit was paid to the astronomical observatory at St. Michel, the visit being of mutual benefit to visitors and residents, for the astronomers there were glad to welcome so much expert opinion on the problems associated with the coating of the mirrors of their reflector telescopes.

On the break-up of the conference everyone felt that he was carrying away many new techniques, little tricks of the trade and valuable 'know-hows', for there was a very frank exchange of knowledge, even from those who represented large commercial organisations, and who might have been forgiven for hesitating to release trade secrets. There were, in fact, no such hesitations, either from the commercial or government representatives who attended, and, indeed, the liaison between the industrial and academic research workers was all that could be desired.

S. TOLANSKY

PHYSICAL SOCIETY

ANNUAL MEETING

AT the annual general meeting of the Physical Society, held at the Royal Institution on May 6, the reports of the Council and Treasurer and the accounts and balance sheet for 1948 were presented and adopted, and the officers and Council for 1949–50 were elected as follows: *President*, Prof. S. Chapman; *Vice-Presidents* who have filled the office of president, Prof. C. H. Lees, Sir Frank Smith, Sir Owen Richardson, Dr. W. H. Eccles, Prof. A. O. Rankine, Mr. T. Smith, Dr. Allan Ferguson, Sir Charles Darwin, Prof. E. N. da C. Andrade, Prof. D. Brunt, Prof. G. I. Finch; *Vice-Presidents*, Dr. W. D. Wright, Dr. W. Jevons, Mr. C. H. Collie, Prof. R. Peierls; *Honorary Secretaries*, Mr. C. G. Wynne, Dr. H. H. Hopkins; *Honorary Foreign Secretary*, Prof. E. N. da C. Andrade; *Honorary Treasurer*, Dr. H. Shaw; *Honorary Librarian*, Dr. R. W. B. Pearse; *Members of Council*, Dr. D. Roaf, Dr. A. C. G. Menzies, Dr. F. C. Toy, Mr. J. H. Awbery, Prof. L. F. Bates, Dr. R. C. Evans, Prof. L. C. Martin, Dr. C. E. Wynn-Williams, Dr. A. G. Quarrell, Dr. A. B. Wood, Prof. Willis Jackson, Prof. H. S. W. Massey.

The officers for 1949–50 of the four Groups of the Society are as follows: *Colour Group:* Chairman, Dr. W. S. Stiles; Honorary Secretary, Mr. R. G. Horner. *Optical Group:* Chairman, Prof. L. C. Martin; Honorary Secretary, Mr. G. S. Speak. *Low Temperature Group:* Chairman, Prof. F. E. Simon; Honorary Secretary, Dr. G. G. Haselden. *Acoustics Group:* Chairman, Mr. H. L. Kirke; Honorary Secretaries, Mr. W. H. Allen and Mr. A. T. Pickles.

During 1948, which the Council report states was a satisfactory year for the Society, there was a net increase in the membership of some six per cent, making the total at the end of the year only a few short of two thousand. Despite the increase in the fellows' annual subscription from two to three guineas, there were very few resignations and lapses. The financial position, though somewhat improved, still gives cause for anxiety.

In addition to the ordinary science meetings, a two-day summer meeting devoted to microwave spectroscopy was held at the Clarendon Laboratory, Oxford, and a full-day meeting at the Research Department of Metropolitan-Vickers Electrical Co., Ltd., Manchester, on surface structure and electrical properties of semiconductors. Prof. E. O. Lawrence was elected an honorary fellow in May, and Prof. R. W. Wood, one of the honorary fellows of the Society, lectured at one of the science meetings on the spontaneous deformation of crystals. The thirty-second Guthrie Lecture was delivered by Sir George Thomson, who spoke on the growth of crystals, and Profs. S. Tolansky and Y. Rocard were the recipients of the fourth (1948) Charles Vernon Boys Prize, and the third (1948) Holweck Prize of the Physica Society and Holweck Medal of the Société Française de Physique, respectively.

The thirty-second exhibition of scientific instruments and apparatus, held in April, had an attendance of about 9,400 visitors, and was again a great success The four subject-Groups of the Society, the Colour, Optical, Low Temperature, and Acoustics Groups, have all been active during the year, and brief details of their composition and meetings are listed in the annual report.

In addition to the *Proceedings*, the publications of the Society during the year included: vol. 11 (1946–47) of *Reports on Progress in Physics*; and special reports such as the "Report on Colour Terminology", the "Strength of Solids", a report of the 1947 Bristol Conference, and "Emission Spectra of the Night Sky and Auroræ". In order to cope with the increased number of papers suitable for publication in the *Proceedings*, and to expedite publication, it was decided that from January 1949 the *Proceedings* should appear monthly in two sections, section *A* covering atomic and sub-atomic physics, including such subjects as crystal structure, quantum mechanics and spectra, and section *B* macroscopic physics, including such subjects as acoustics, optical design and radio. A new feature, introduced in 1948 and now appearing regularly in the *Proceedings*, is "Letters to the Editor", a section similar to that of the same name appearing in *Nature*.

It is to be hoped that the sales of the special reports will improve, so that the decision of the Council to curtail the production of these reports will be rescinded.

S. WEINTROUB

THE SMITHSONIAN INSTITUTION

REPORT FOR 1947–48

THE report of the Secretary of the Smithsonian Institution for the year ended June 30, 1948*, again emphasizes the handicap placed on the work of the Institution by shortage of staff and of adequate buildings. Additions to the collections of the National Museum during the year numbered 507,000, and field parties from the Museum visited Arnhem Land in Australia, the antarctic continent, the Bikini area in the Pacific, the Persian Gulf, Colombia, Panama, and other parts of the world. The Department of Biology has been divided into those of Zoology and Botany, and the Division of Aeronautics has become the nucleus of the National Air Museum.

The director of the Bureau of American Ethnology conducted archæological excavations in western Panama in co-operation with the National Geographic Society, discovering a new, very early culture, while the associate director of the Bureau was occupied mainly with the river basin surveys. Surveys made in eighteen States and thirty-eight reservoir areas have led to 250 sites being recommended for excavation to recover archæological material which might be lost through the construction of dams and river valley reservoirs. An autonomous unit of the

---

* Report of the Secretary of the Smithsonian Institution and Financial Report of the Executive Committee of the Board of Regents for the Year ended June 30, 1948. (Publication 3952.) Pp. ix+158. (Washington, D.C.: Government Printing Office, 1948.) 55 cents.

Bureau, the Institute of Social Anthropology, gave courses in anthropology and conducted co-operative field work in Brazil, Columbia, Mexico and Peru.

The International Exchange Service made the first shipments of exchange publications to Japan since the War, and now sends consignments to all countries except Roumania. In return for similar material received from other countries, ninety-four sets of United States official publications, seventy-three copies of the Federal Register, and sixty-six copies of the Congressional Record were sent abroad. Visitors to the National Zoological Park increased by more than 300,000, and the collection at the close of the year totalled 2,797 animals representing 690 different species. The Astrophysical Observatory terminated the sun and sky radiation studies at Camp Lee, but similar studies will continue at the Montezuma and Miami stations. Promising sites for a new high-altitude station were located in Mexico, southern California, and the Hawaiian Islands. The Division of Radiation and Organism substantially completed its studies of the respiration of broad-leaf plants, the effects of environmental factors on the germination of lettuce seeds, and the developmental physiology of grass seedlings.

A total of 165,740 copies of Smithsonian publications was distributed during the year, and a complete list of the publications during the year is appended. The Library received 53,129 publications, and 36,701 pieces from its collection of duplicates were selected for destroyed libraries overseas. About half the 915,987 volumes of the Library are housed as the Smithsonian Deposit in the Library of Congress. The financial report of the executive committee of the Board of Regents and the usual departmental reports are appended.

LICHENS OF ANTARCTICA

IN a vegetation devoid of vascular plants, as the antarctic continent is generally believed to be, the lichens assume a quite unusual importance. The meticulous study of the lichens of Antarctica and the subantarctic islands recently published (B.A.N.Z., Antarctic Research Expedition Report. Vol. 7, Lichens and Lichen Parasites, by C. W. Dodge. Adelaide, 1948) is therefore a very significant contribution to knowledge of these remote and inhospitable regions, incomplete as it must necessarily be.

The material was collected by several different expeditions, the Australian Antarctic Expedition of 1911–14, the British, Australian, New Zealand Expedition of 1929–31, and there is some residual material from the British Antarctic Expedition of 1907–9. Unfortunately, a large part of the collections from the subantarctic islands of the Indian Ocean visited by the 1929–31 expedition was lost during the bombing of London, having accidentally been sent to the British Museum; but it is indeed fortunate that the bulk of the collections had been sent to the Herbarium of the Missouri Botanic Garden, in which the most complete set has been retained, and that Dr. Dodge was free to devote the very considerable amount of skilled attention to them that this publication obviously shows.

It is not profitable to summarize the purely taxonomic side of the work which will only concern the specialist, but no plant geographer can afford to ignore the implications of geographical distribution outlined in the introduction. Three totally distinct floras are discerned, that of Antarctica itself, which is still very imperfectly known, that of Macquarie Island, which seems wholly unrelated to it though with some affinities with both New Zealand and Tasmania, and thirdly "Kerguelia", which is the name used to cover Kerguelen Island, Heard Island, the Crozets and Prince Edward Island groups.

The lichen flora of Kerguelia is remarkable for the very high proportion of endemism in it, possibly all, and certainly 118 out of the total of 124 known species, being in this category. This can only mean very prolonged isolation. The generic affinities, many of which are also endemics, are, however, of even greater interest since they seem to imply remote physical connexions of some kind over immense distances in the most diverse directions, which include Fuegia, the Auckland Islands, South Africa and the Andes. Evidence of this kind, though insufficient in itself to establish major hypotheses such as that of continental drift, is nevertheless closely cognate to any discussion of such problems. This is perhaps the most important aspect of the study of lichen distribution in the southern hemisphere, since lichens, more perhaps than any other form of plant life, have special limitations in their mode of distribution over long distances. It is therefore greatly to be hoped that further contributions will in due course be made to this very promising, though hitherto much neglected and difficult, field of inquiry.

FORTHCOMING EVENTS

Tuesday, June 7

British Society for the History of Science (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Dr. A. C. Crombie: "Theory and Experiment in the Science of Robert Grosseteste"; Mr. H. C. King: "The Optical Work of Charles Tulley".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. Åke Campbell: "The Colonization of Lappland and Culture Contacts between Farmers and Nomads".

Wednesday, June 8

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Symposium on "Combustion of Hydrocarbons".

Thursday, June 9

Royal Statistical Society, Research Section (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 2.30 p.m.—Symposium on "Stochastic Processes".

Research Defence Society (at Manson House, Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 3.15 p.m.—Annual General Meeting; Prof. C. Lovatt Evans, F.R.S.: "Physiological Research and the Vivisection Act" (Eighteenth Stephen Paget Memorial Lecture).

Friday, June 10

Physical Society (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Mr. T. Smith, F.R.S.: "The Contributions of Thomas Young to Geometrical Optics, and their Application to Present-day Questions" (Thomas Young Oration). (Members of the Optical Group are invited.)

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Prof. S. W. Wooldridge: "The Structure and Morphology of the Country around Fernhurst, Sussex".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Chemistry—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1 (June 11).

Lecturers in Biological Subjects (Botany and Zoology)—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (June 11).

Assistant Lecturer in the Department of Philosophy—The Registrar, The University, Liverpool (June 11).

Readership in Applied Physiology at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 13).

Lecturer in Engineering—The Registrar, King's College, Newcastle-upon-Tyne (June 15).

Director of the Commonwealth Bureau of Dairy Science, Shinfield, Reading—The Secretary, Commonwealth Agricultural Bureaux, 2 Queen Anne's Gate Buildings, London, S.W.1 (June 15).

Senior Lecturer (Grade I) in Horticultural Science—The Secretary and Registrar, The University, Bristol (June 20).

Lecturer or an Assistant Lecturer in Mechanical Engineering, and an Assistant Lecturer in Mathematics—The Registrar, College of Technology, Manchester 1 (June 20).

British Coke Research Association Fellowship—The Registrar, King's College, Newcastle-upon-Tyne (June 21).

Gas Light and Coke Company Research Fellowship in Gaseous Fuel and Combustion—The Registrar, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (June 24).

Lecturer in Electrical Engineering—The Registrar, The University, Leeds 2 (June 25).

Research Officer in the Wool Textile Research Section (Ref. No. 2031), at Geelong, and a Research Officer in the Division of Industrial Chemistry (Ref. No. 2159), at Fishermen's Bend, Melbourne, of the Australian Council for Scientific and Industrial Research—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (June 25).

Assistant Lecturer in Botany, and Assistant Lecturers (2) in Zoology—The Registrar, The University, Reading (June 27).

Agricultural Economist in the Department of Agriculture—The Registrar, The University, Leeds 2 (June 27).

Lecturer in Bacteriology—The Secretary, The University, Birmingham 3 (June 30).

Experimental Officers (2, one for work on cereal breeding, and the other for work on potato breeding), a Scientific Officer for work on genetical and cytological problems, and a Senior Scientific Officer to work on genecological problems of the herbage plant section dealing with the distribution of intra-specific variation in wild and cultivated plants—The Secretary, Scottish Society for Research in Plant Breeding, 8 Eglinton Crescent, Edinburgh 12 (June 30).

Senior Lecturer in Engineering Physics, Senior Lecturers (2) in Electrical Engineering, and a Lecturer in Electrical Engineering, at the Military College of Science, Shrivenham, Swindon—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2576 (June 30).

Curator of the Department of Natural History in the Museum, Kelvingrove, Glasgow—The Town Clerk, City Chambers, Glasgow, C.2, endorsed 'Curator of the Department of Natural History' (June 30).

Senior Lecturers in Veterinary Pathology, in Veterinary Anatomy, and in Veterinary Physiology—The Secretary and Registrar, The University, Bristol (June 30).

Research Officers (3) to work on sugar beet breeding, leguminous forage crop breeding, and cytogenetic investigations—The Secretary, School of Agriculture, Cambridge (June 30).

University Lecturer in Theoretical Electrodynamics and Radio—Dr. F. B. Kipping, Chemical Laboratory, Cambridge (July 1).

Experimental Officer for supervision of metallurgical laboratory, and an Assistant Experimental Officer for interpretation of analyses primarily with casting, hot and cold working of non-ferrous alloys, in a Ministry of Supply factory in Co. Durham—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.366/49A (July 6).

Inspector under the Dangerous Drugs Acts, in the Home Office—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 2596 (July 7).

Readership in Anatomy at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 7).

Lecturer in Forestry—The Secretary, The University, Aberdeen (July 21)

Senior Lecturer in Mathematics (Statistics) at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 30).

Research Chemist for work on the development of new methods of chemical analysis—The Director, British Cast Iron Research Association, Alvechurch, Birmingham.

Entomologist (male) for service with a research unit undertaking a large-scale mosquito eradication experiment in Mauritius using D.D.T. and B.H.C. insecticides—The Under-Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer (Grade II) in Organic Chemistry, an Assistant Lecturer in Physical Chemistry, a Demonstrator in Physical Chemistry, and a Demonstrator in Organic Chemistry—The Registrar, The University, Nottingham.

Senior Technician and a Technician in the Department of Pathology—The Superintendent, Royal Infirmary, Infirmary Road, Sheffield 6.

Lecturer in the Department of Chemistry and Metallurgy, and a Lecturer in the Department of Physics and Electrical Engineering—The Director of Studies, Royal Naval College, Greenwich, London, S.E.10.

Agricultural Chemists in the Colonial Service in East Africa, West Africa and the Federation of Malaya—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Technician (Grade IV) in the Department of Physics—The Secretary, University College, Gower Street, London, W.C.1, quoting Physics/3.

Senior Assistant for the teaching of Organic Chemistry up to Final Special B.Sc. standard, and a Lecturer in Mathematics to B.Sc. Engineering and B.Sc. General Degree—The Principal, Medway Technical College, Gillingham.

Assistant Experimental Officers (covering a wide variety scientific, including engineering, qualifications) in various Governm Departments—The Secretary, Civil Service Commission, Scient Branch, 27 Grosvenor Square, London, W.1, quoting No. 2522.

Veterinary Research Officer in the East African Tsetse a Trypanosomiasis Research and Reclamation Organisation, for wo in connexion with the trypanocidal drug 'Antrycide', and a Veteri ary Research Officer (Animal Husbandry) in the East Afric Veterinary Research Organisation—The Under-Secretary of Sta Colonial Office, Research Department, Sanctuary Buildings, Gre Smith Street, London, S.W.1.

Senior Lecturer in Building Science at the Leeds College Art (School of Architecture)—The Director of Education, Educati Offices, Leeds 1.

University Lecturers (2) in Mathematics (with special qualific tions either in Algebra or in Quantum Theory), and Universi Assistant Lecturers (2) in Mathematics—Dr. A. J. Ward, E manuel College, Cambridge.

Superintending Pharmaceutical Chemist for the Medical D partment, Government of Federation of Malaya—The Crown Age for the Colonies, 4 Millbank, London, S.W.1, quoting M.N. 18288/3

Laboratory Technician (Grade III) in the Department Pharmacology—The Secretary, University College, Gower Stre London, W.C.1, quoting Pharmacology/2.

Chief Chemist for the Process Control Laboratory, East Afric Industrial Management Board, Nairobi, Kenya—The Crown Agen for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.21789/3E.

Electrical Engineers for the Electricity Department of t Federation of Malaya—The Director of Recruitment, Colonial Offic Sanctuary Buildings, Great Smith Street, London, S.W.1, quoti No. 27326/18.

Technician for Hæmatological Department—The Direct Ashford Hospital, Ashford, Middx.

Cerealist for the Directorate-General of Agriculture, Governme of Iraq—The Crown Agents for the Colonies, 4 Millbank, Lond S.W.1, quoting M.N.18187/3F.

COLONIAL DEVELOPMENT AND WELFARE

THE full statement which the Minister of Food, Mr. Strachey, made in the House of Commons on the East African groundnut scheme on March 14 did not dispose of some of the criticism; on the whole, however, with some assistance from the Opposition, he succeeded in putting the scheme in its true perspective in terms of Colonial development. The public has hitherto regarded the scheme as essentially one to produce oils and fats, for which the fact that the Minister of Food was made responsible for the scheme was undoubtedly a contributory factor. The scale of the scheme is now to be reduced; but Mr. Strachey rightly refused to regard the production of oils and fats as unimportant. The world need of fat supplies is as great as ever, and whether or not the revised scheme will give, as is claimed, the same yield of oils and fats, the importance of that aspect remains, even if it is secondary to the main purpose of Colonial welfare and development.

Mr. Strachey stated that the acreage to be cleared in the three East African areas is to be reduced from three and a half to two millions, and that the Overseas Food Corporation estimates that, working to the ten-year plan, the new acreage will give the 600,000 tons of oil-seeds originally forecast. A higher yield would be made possible by including sunflowers in the rotation of crops. Development of the Kangwa area, where practically all the clearance has so far been done, will be restricted in favour of the more promising western area of Urambo and the southern area of Tanganyika; but Mr. Strachey advanced no evidence that better preparation has been made in the southern area, where admittedly no clearing has yet been done.

On such technical points there was surprisingly little comment in the debate in the House of Commons; but such factors will have a very important bearing on the expenditure involved. It was admitted by Mr. Strachey that the cost of the scheme may well be double the original estimate. That estimate may be accepted; but there will be less confidence in his estimate that revenue will also be doubled. Inflation has greatly exaggerated the world shortage of fats, and informed opinion is at least doubtful whether the price of groundnuts is likely to remain at the level of £51 a ton which the Ministry of Food is at present paying in its long-term contract for main supplies from West Africa. That price represents an increase of £6 a ton on the 1947–48 price, and, to say the least, it is unreasonable to expect the British taxpayer to permit the Minister of Food indefinitely to pay an inflated price in long-term contracts and ignore any fall in world prices.

Nevertheless, whatever the financial shortcomings of the scheme, Britain is now committed too deeply for it to be abandoned unless it is proved to be impracticable agriculturally. The best opinion is against so pessimistic a conclusion, and the reforms announced by Mr. Strachey appear to be sound. The revised plan will, however, require vastly improved methods of organisation if it is to succeed, and Mr. Strachey did not conceal the problems which are presented by such matters as stores, tractors and other equipment, and port and railway extensions. Much careful planning and preparation are needed, for these matters are not without bearing on other economic developments, as Mr. Strachey indicated in relation to the railway developments in the Lukeledi valley, which are to provide an outlet to the new port of Mikidani from the groundnut area.

The scientific and technical factors were chiefly stressed in the debate by Mr. Henderson Stewart, who rightly directed attention to the time required to be certain we had found the right solution to problems of cultivation, agricultural implements, the rotation of crops, fertilizers and so on. This speech drew from Mr. Strachey a repudiation of any suggestion that the Government had attempted to drive the Corporation or the managing agency at an unreasonable speed. But it must be recognized that long-term and short-term requirements are not always compatible; the Government has tended hitherto to overstress the short-term aspect of the scheme, and its reluctance to provide a report or 'white paper' in advance of the debate has not made it easy to correct that impression.

Two things at least the debate has done. From all sides of the House, members joined with Mr. Strachey in commending the personal devotion and enterprise of the Europeans working on the scheme in East Africa, and the debate should dispel any lingering ideas that criticism of the scheme should be levelled against those responsible for its execution in Africa. It was, indeed, suggested that the proportion of Europeans to Africans engaged in the scheme is considerably higher than originally envisaged—one to eleven instead of one to every thirty or forty Africans—and concentration of the Europeans on scientific, technical and supervisory tasks to the maximum extent should reduce the administrative and overhead costs. Mr. Frederic Harris also suggested that splitting up the 30,000-acre units into units of 5,000–8,000 acres for private development was a sensible proposition which should also be tried.

Above all, the debate brought out the welfare aspect of the scheme. The Minister of Food spoke of the benefit which would accrue to the African peoples once the project is fully under way; already, he said, there is evidence of benefit to health through the improved nutrition of those participating in the scheme. He might, indeed, have said more about the difficulties of maintaining a steady labour force and the measures that will be required to overcome them. Nevertheless, it can no longer be pretended that the scheme is one of exploitation of African resources for the benefit of the rest of the world; it is essentially a long-term development scheme in which the primary purpose is Colonial welfare, while simultaneously serving the world's needs for oils and fats.

The welfare aspect must, indeed, be kept in mind if the economic aspects of the scheme are to be considered fairly, whether from the point of view of the Colonial people or of the British taxpayer. The debate is one, therefore, to be considered in the context of a subsequent debate on Colonial policy and administration in the House of Lords on April 1 Against this background, too, should be reviewed th recent reports from the Colonial Office on the pro duction of fish in the Colonial Empire and on th work of the Colonial Primary Products Committee A large part of the latter report, in fact, deals wit vegetable oils and oil-seeds and with essential oil and in introducing the report the Committee refe particularly to the bearing of price, particularly o the production of oil-seeds.

Before the Second World War, the primary produce was often penalized by fluctuations in commodit prices on world markets. Marketing schemes established during the War for various Colonial product often paid producers a fixed price for the whol season, and producers of annual crops were guarantee prices for their produce before the planting seaso began. Since the assurance of a reasonable pric tends to encourage the planting of annual crops, continuance of such schemes, suitably modified, shoul increase production; and the system has the furthe advantage that central organisation can accumulat funds at times of high prices and subsidize prices pai to producers when world prices fall, thus cushionin producers to some extent. The Colonial Primar Products Committee in its report welcomes the polic of long-term contracts pursued by the Government particularly for tree crops and where capital development is involved. Quoting the text of the statemen made by the Chancellor of the Exchequer on September 17, 1948, in regard to such guarantees fo Colonial produce, it suggests that similar considerations might govern the conclusion of contracts fo commodities bought by other control buying organisations or associations of users or manufacturers.

It does not appear, however, that Mr. Strache has yet fully appreciated the implications of th Chancellor's observations on price, or on the imperative need for establishing beyond question communit of interest and co-operation if misunderstandings ar not to arise and justice is to be done between th primary producer and the ordinary citizen of Grea Britain. Moreover, as the Colonial Primary Product Committee has noted, where a crop such as oil-seed in West Africa is largely a cash crop, high prices will not result in increased production if there is a shortag of consumer goods. Lord Swinton did well to explain, in opening the House of Lords debate, the interdependence of economic prosperity, health and practical education in the Colonial areas, and the way in which the needs of the Colonial peoples are linked with the needs of people in Britain.

The commodity studies presented in this second report from the Colonial Primary Products Committee are reviewed elsewhere (p. 898 of this issue); it is sufficient here to note that the Committee takes the view that semi-mechanized methods for the cultivation of such crops as groundnuts and sunflowers are unlikely to be introduced rapidly into West African territories. It will probably be necessary to start with pilot schemes, the results of which must be available before production can begin on a larger scale. Similarly, experiments on a large scale over a period of years will be required before any ound conclusions can be reached as to the possibilities or groundnuts in British Honduras.

The improvement of material conditions must learly come first, and the debate in the House of ords brought out the need for a coherent and onsistent policy in Colonial administration. Without hat, neither British nor Colonial scientific workers, even with the help of American technical experts, ill secure the physical development of mineral ealth or other natural resources, water supplies or ransport, or the improvement in health and social elfare which could follow the application of advances n knowledge of nutrition, preventive and curative nedicine and the like. There must be a balance between such measures and those taken in the conomic and political field.

Lord Swinton, at the outset of his speech, enunciated five principles which should guide British Colonial policy and the planning of Colonial development. First, we are trustees for the whole of the Colonial peoples and not for a section or a minority. Secondly, the primary need of all these peoples is improved health and well-being, and the true liberty of he individual to enjoy them. Thirdly, economic and social progress depends on co-operation between the European and the indigenous populations. Fourthly, he ultimate goal is self-government, the evolution of which may be infinitely varied ; and last, that the prerequisite of self-government is the capacity to govern.

These five points were accepted on behalf of the Government both by Lord Pethick-Lawrence and by Lord Listowel. Nevertheless, there remains some doubt whether in practice the tempo of political development is quite in keeping with the first and last points, and whether there is not danger that too much regard is being had to the demands of a more vociferous minority. As Lord Swinton said in amplifying his last point, without effective government here can be no freedom for the individual, and while all suffer, the ordinary man suffers most.

It will not, and cannot, be easy to arrive at a balance which will satisfy all, and the balance must be struck for each territory in the light of the circumstances which prevail there. The Colonial Office tends to be over-cautious and, although sections of the ocal population may be over-eager or over-sensitive in the matter of political independence, the Colonial Office must none the less show more imagination and the leadership which inspires confidence. The points made by Lord Swinton provide some guide in working out a practical policy, particularly when three important points stressed by Lord Tweedsmuir are also remembered. Political independence can only come about when economic independence has been secured, and only then when the capacity for government exists. In all African Colonies and in many others, the Colonial peoples cannot make headway at present without European leadership, and European capital and technical help ; and that help will count for nothing unless we can take some Colonial peoples along with us in partnership. The second of those points was strikingly emphasized by Dr. C. H. Northcott in his recent report on the efficiency of African labour.

Hence Great Britain has still a great part to play in the future of the Colonial peoples, and it is important that at the centre there should be clear and constructive leadership, and that malicious criticism frequently levelled against Great Britain and other Colonial Powers should receive a positive answer. The United Nations Scientific Conference on the Conservation and Utilization of Resources meeting this summer at Lake Success will provide emphatic evidence of the British contribution to Colonial welfare. An even more important contribution of the Conference may be in furthering both the indispensable co-operation between the Colonial Powers and the Colonial peoples, and in shaping regional and other forms of co-operation between the Colonial Powers which will enable scientific and technical advances to be brought most swiftly and effectively to bear on the economic and social problems of the Colonial peoples. Nothing in Lord Listowel's reply was more welcome than his recognition that education is the vital social service, and that teaching people to govern themselves in local communities provides the real basis of political advance.

PROBLEMS OF ORGANIC FORM

Organic Form and Related Biological Problems

By S. J. Holmes. Pp. vii+169. (Berkeley and Los Angeles : University of California Press ; London : Cambridge University Press, 1948.) 27*s.* 6*d.* net.

THE title of this book is aptly descriptive of the contents. In a series of related essays, the author has discussed the factors which determine form in living organisms. It is difficult to do justice to a work such as this in a short review, for the author has succeeded in saying so much, and that with an illuminating perspicacity, that is cogent in each of his condensed chapters. These are concerned with an inquiry into the problem of organic form, the functional aspect of morphogenetic processes, competition as an integrative factor in morphogenesis, differentiation, chemical equilibrium and organic integration, and so on. On each theme, the leading ideas that at one time or another have been held are clearly set out, and an attempt is made to find a sure way to explanations of a valid kind. In these discussions the author's fairness and balance are a striking feature ; his contribution is patently the result of long and deep pondering of central themes in contemporary biology.

In every normal embryonic development the impressive facts are the formation and divergent development of the component parts or organs, their regular appearance in their proper positions, and the regulation and harmony of morphogenetic processes that result in the characteristic development of the whole. How are these phenomena to be explained, and what kinds of explanation are likely to prove acceptable to the contemporary biologist ? On such problems much new light is shed by the analytical approach adopted in this work. In the author's view, morphogenetic and related processes can be referred to biochemical and biophysical processes which are ultimately gene-controlled, that is to say, an epigenetic and mechanistic view of formative processes in plants and animals is upheld, the genes themselves being seen in relation to the evolutionary background. As a sample of the author's style, reference may be made to his chapter on "Genes *versus* Gradients": "If a viable organism is to be made, its parts must be of the right kind, in the right place, and appear at the right time. If oaks, oysters, grasshoppers, and elephants all owe their initial patterns to their metabolic gradients, we must look to other factors to account for the marvellously co-ordinated processes that give rise to these very different styles of organic structure." The decision is heavily in favour of the genes as the physiological agents chiefly involved: "As more becomes known about the relative roles of genes and cytoplasm in heredity and developmental physiology, the more basic the influence of genes is found to be".

Other chapters deal with cancer as a biological problem, the idiosyncrasies of direct adaptation, autocatalytic enzymes and the origin of life, and recapitulation and its supposed causes.

There can be no doubt that in these papers the author has made a significant contribution to modern biology. He has succeeded in giving a clear impression of the aims and outlook of the experimental biologist and in showing how adequate, on the whole, such an outlook can be.

SOUTH AMERICAN BOTANY

La vegetación del nordeste de la Provincia de Entre Ríos

Informe cientifico. (The Plant Cover of the North-east of the Province of Entre Ríos: Scientific Report.) Por P. G. Lorentz. Second edition. Pp. xi+180+xiii+3 plates. (Paraná: Talleres Gráficos Pattarone y Sors, 1947.)

Observaciones sobre la vegetación de la Provincia de Tucumán

(Observations on the Vegetation of the Province of Tucumán.) Por G. (J.) Hieronymus. (*Mon. Inst. Est. Geogr. Univ. Tucumán*, No. 5.) Second edition, revised and with critical notes by Hans Seckt. Pp. 162. (Tucumán: University of Tucumán, 1945.)

Esquisse de mes voyages au Brésil et Paraguay, considérés principalement sous le rapport de la botanique

(Sketch of my Travels in Brazil and Paraguay, with special reference to the Botany of those Countries.) Par A. de Saint-Hilaire. (*Chronica Botanica*, Vol. 10.) Pp. 61. (Waltham, Mass.: Chronica Botanica Co. London: Wm. Dawson and Sons, Ltd., 1946.)

THE work of the botanical pioneers in South America appeared for the most part in the form of pamphlets or monographs which soon became exhausted and inaccessible to later generations, or else it was published in equally inaccessible, obscure periodicals. Most of it was, however, work of great importance and the foundation upon which subsequent research, at all events for certain regions, has been built. For this reason the recent re-publication of some of the outstanding earlier work is a welcome addition to the botanist's armoury, and it is to be hoped that more will follow.

The last to appear has been P. G. Lorentz's classic report on the plant cover of the Argentine Province of Entre Ríos, first published in 1878 and now r issued by the Municipal Cultural Commission o Paraná and the Museum of Entre Ríos at the decre of the Provincial Government. The reproduction i an exact one, without any kind of correction, an reflects faithfully the conditions under which Lorent was working, conditions described also by J. F Báez, who writes the introduction and an appendix Lorentz had the entire goodwill of the Argentin Government of his day and every material assistanc that it was able to afford him; but the nationa exchequer had been so greatly impoverished as result of revolution and counter-revolution that th botanist, fresh from the well-equipped universities o Germany, described himself as "a scientific Robinso Crusoe", lacking the most elementary scientific equipment and especially hampered by the lack of books He was, in addition, dogged by persistent ill-healt which cut his career short in 1881. But his affectio for the country of his adoption was great and hi enthusiasm for his work unbounded, so that, lecturin during term-time at the College of Concepción on th River Uruguay, and, accompanied by some of hi students, exploring the countryside on horseback i the vacations, he assembled an enormous mass o material and information. Most of this is crystallize in the book now reproduced. When for lack of work of reference Lorentz was unable to classify plant himself, he sent them to Prof. Grisebach, of Göttingen for identification.

The work has three chapters. The first (pp. 3–47 contains a general description of the flora of such o Entre Ríos as Lorentz had been able to explore u to 1876. This embraced the north-eastern part from Concepción northwards as far as the junction of the Rivers Mandisobi Grande and Mandisobi Chico, and part of the woodland known as the Montiel. Some of the account takes the form of a diary describing a tour made in 1876. Practically the only form of use to which the country was put in Lorentz's day was a haphazard type of stock raising; but he was impressed by the fertility of the land and foretold a great future for the Province if at least a part o it were devoted to cropping. This has now taken place, and photographs published by J. L. Rich in "The Face of South America, an Aerial Traverse" (New York, 1942) clearly display a land of well-watered plains or gently undulating land with rich black soils, a large proportion of which are occupied by various cultures.

The second chapter (pp. 49–102) lists 620 species of flowering plants and 32 fungi collected by Lorentz and identified by him or by Grisebach of Göttingen. Notes are given on habitat, popular name, flower colour or other salient characters, growth habit, time of flowering, and in some cases the uses of each species. The achievement was a remarkable one. Until the arrival of Lorentz in Argentina, said Holmberg as quoted by Báez, the flora of that country consisted not of plant species but merely of grass and timber.

The third chapter (pp. 103–180) is entitled "Phytogeographical Relations" and compares the flora of Entre Ríos with that of the interior. For the interior, 100 families, 451 genera and 960 species are recorded, for Entre Ríos 98 families, 346 genera and 620 species. The flora of Entre Ríos is considered poor in relation to the geographical position, climate and soil of the Province, the poverty being attributed to the youth of the country. A list of 1,481 Argentine plant species is given (pp. 124–157), with notes of their presence or absence and frequency in Entre ios, the interior *monte* or scrub forest and the sub-opical parts of Argentina respectively, and the gional affinities and differences noted are discussed. he Entre Ríos flora is distinct and independent, onstructed on the same plan as that of the *monte* and the sub-tropical regions, but with different lements. It would probably not be equally independent if compared with the flora of southern razil. Natural plant colonization in Argentina is principally from the north.

A contemporary of Lorentz in Argentina was another German botanist, Georg Hieronymus, who as professor of botany in the University of Córdoba; and the two collaborated in collecting and classifying large amount of botanical material from Central rgentina. It is on the results of their joint work that many of Lorentz's conclusions recorded above ere based. Like Lorentz, Hieronymus did not conne himself to the systematics of the Argentine flora, but was intensely interested in its distribution as overned by climatic and environmental conditions. He published in 1874 a treatise on the plant cover of the Province of Tucumán, which was the foundation f all subsequent botanical work on that region; but or many years it had become quite unobtainable for the ordinary worker and was difficult to find even in braries. Its republication by the Institute of Geographical Studies of the Tucumán University, therefore, has satisfied a real need. Although its general terminology has been modernized by the reviser, H. Seckt, who has also supplied critical notes n Hieronymus's taxonomy, but without changing the ames used, the work remains practically unaltered nd is entirely pertinent to present-day conditions. An introductory chapter lists some fourteen different ormations which make up the plant cover of Argentina generally, and those found in Tucumán are enumerated in the next chapter. Subsequent chapters ive a detailed account of the different types of rassland found in the eastern plains of the Province, f marsh vegetation and water plants, of the different ypes of forest and woodland and their components (pp. 56–128), and finally of the mountain plant ormations with no characteristic tree growth but a ward composed of grasses in association with shrubs nd herbaceous plants. A map of the vegetation is ppended, drawn in accordance with the formations s described by Hieronymus.

The third reprint to which attention is directed here is the reproduction in *Chronica Botanica* of the introduction to Auguste de Saint-Hilaire's great work n the plants of Brazil and Paraguay, published in 1824 and, according to Castellanos and Pérez-Moreau's bibliography of botanical works on Brazil *Lilloa*, 7, 431; 1941), the earliest study of the Brazilian vegetation except one published by Spix and Martius in 1823.

The area traversed by Saint-Hilaire in 1816–22 was small in relation to the whole, vast extent of Brazil; ut it was representative and enabled him in this 7-page introduction alone to give a picture of most f the characteristic Brazilian plant formations and f the flora of Uruguay and the east of Paraguay. Before the advent of the French explorer practically nothing was known of the flora and fauna of these egions. Among interesting descriptions may be noted those of the typical Brazilian bush named *caatinga*, of the *sertão* or hinterland of Minas Gerais, and of the Uruguayan grasslands, of which he says: "Nowhere, perhaps, do better pastures exist". To Lorentz in Argentina the results of civil dissension were ever-present in the form of straitened means and the depleted animal population of Entre Ríos; to Saint-Hilaire in Uruguay and the La Plata region they were manifest in the amazing spread of weed growth and especially of the European *Cynara cardunculus*. Before the war which had just taken place, he wrote, the young shoots of this plant were eagerly grazed and the plant itself was prevented from spreading unduly, but with the war-conditioned destruction and loss of cattle all limiting influences were removed. "*Cynara cardunculus* to-day covers immense terrains; it makes them useless for cattle and horses and it will be an indestructible monument of the civil discords which have rent this fair country." It is only now, more than a century later, that Uruguay is beginning to see an end of this weed problem, one valuable solution being the cutting of *C. cardunculus*, *Silybum marianum* and similar weeds for silage. The silage produced is highly nutritive, and the cutting tends to clear areas of the undesirable plants and to make room for better (A. Boerger. "Investigaciones agronómicas." Vol. 2. Buenos Aires, 1943). An introductory essay by Anna E. Jenkins precedes the reproduction of Saint-Hilaire's work.

G. M. Roseveare

ADVANCES IN ELECTRONICS

Advances in Electronics
Edited by L. Marton. Vol. 1. Pp. xi+475. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1948.) 9 dollars.

THE "Reports on Progress in Physics" have always fulfilled a valuable function in acquainting the specialist in any one of the physical sciences with progress in cognate subjects. These "Reports" cover the whole range of physics, and it was felt that electronics, though a part of physics, so spilled over into electrical engineering and had grown to such a size that a volume of review articles confined to electronics was needed. Dr. L. Marton, now of the Bureau of Standards, has undertaken this task as editor, and the first volume has just been published. Although this is an American publication, it intends to draw freely upon European men of science for review articles, and already plans for volumes 2 and 3 include a number of British contributors. Volume 1 is written entirely by American men of science, but this was due to the difficulties encountered in launching the new venture.

In the preface, Dr. Marton points out that "Advances in Electronics" will be confined to the physics of electrons in the free state—emission, space-charge effects, interaction, etc.—and to the engineering applications of a fundamental character, avoiding so far as possible discussion on instrumentation and circuitry. The contents of volume 1 certainly bear out the policy he outlines.

Electron emission is dealt with in two long articles, A. S. Eisenstein on "Oxide Coated Cathodes", and K. G. McKay, of Bell Telephone Laboratories, Inc., on "Secondary Electronic Emission"; both are most exhaustively treated with what appear to be complete bibliographies over the past decade. Eisenstein's review brings up to date J. P. Blewett's 1939 résumé of the subject, and includes the important war-time research on cathodes in magnetrons and valves pulsed for times of the order of microseconds.

The results of this work focused attention on the importance of the interface between the base metal and the oxide layer, and a whole section of the review is devoted to our present knowledge of the interface and its probable rectifying properties. A further important section reviews the known properties of the complete cathode, and includes the probe experiments and the phenomenon of sparking, all of which have only been reported upon since the War. McKay divides his subject into emission from pure metals and emission from insulators, and includes a summary of early work, since the standard reference hitherto has been in German. It is interesting to learn how little modern work has been done on the velocity of emission of secondary electrons, a field obviously ripe for further exploration. Practically the whole of the long section of the emission from insulators is based on research published since 1939 and is of great importance.

R. G. Hutter contributes an original article on the deflexion of beams of charged particles, a subject which has received far less attention than the focusing of beams by lenses; he deals with single and double electric and magnetic deflexion, with large-angle deflexion, and with the many mixed deflexions in mass spectrometers. M. G. Inghram, of the Argonne Laboratory, supplements this with an article on mass spectroscopy, in which the use of the spectroscope is treated. It was surprising to find no mention of the calutron in an article on mass spectroscopy.

The television pick-up tube has become a third method of visual examination supplementing the eye and the photographic plate. Apart from use in the entertainment world, the television tube has an important future in the research laboratory, and men of science will turn to A. Rose's article on "Television Tubes and the Problem of Vision" to find out the ideal performance of tubes and the degree to which present-day tubes achieve this ideal.

The last article on particles is a review by M. S. Livingston on "Accelerators"; but for readers in Great Britain there is already a recent review in the current "Reports of Progress in Physics", which practically covers the ground.

The importance and fickleness of the ionosphere and the irritating habits of the cosmos are treated by A. G. McNish in "Ionospheric Research" and by J. W. Herbstreit in "Cosmic Radio Noise"; both men work in the Bureau of Standards, and their reports cover almost exclusively the post-1939 research. McNish points out that much more data are required on a world-wide basis, and a comprehensive theory of the ionosphere which will explain the complex features discovered during the War is needed. Cosmic noise has been shown to be so important that the lowest usable field intensity for radio communication is set by it. Its origin is still obscure, and the study of cosmic noise is another approach to the understanding of the heavens.

"Propagation in the FM Broadcast Band" is reviewed by K. A. Norton. It may come as a shock to readers that, within a year, the frequency-modulation broadcast stations in the United States will probably exceed the pre-war number of conventional amplitude-modulation stations, and a review of the factors which influence frequency-modulation propagation is most timely. Frequency-modulation avoids to a large extent the interferences reviewed in the two previous articles; but Norton emphasizes that we are still only beginning to learn about propagation characteristics in the frequency-modulation band—nc set at $\sim$ 100 Mc. in the United States. The artic will be eagerly read in Great Britain by advocat and opponents of the system.

The last article is by J. A. Pierce, on "Electron Aids to Navigation", and includes all the war-tim developments in this subject; but the article do not carry a single reference, so that the resear worker will not be in a much better position f further study.

The book is very well presented and appears have few blemishes. If future annual volumes are good, the "Advances in Electronics" will have important place on our bookshelf.

T. E. ALLIBONE

THE BADGER AT HOME

The Badger

By Ernest Neal. (New Naturalist Monograph Series Pp. xv + 158 + 25 plates. (London and Glasgow Wm. Collins, Sons and Co., Ltd., 1948.) 12*s*. 6 net.

THIS monograph on the badger by Ernest Ne is, I think, the best book that has been publishe on this nocturnal animal. The author has a literall astonishing knowledge of the badger and its habit and he is able to set down this knowledge in a attractive form and in good and readable prose. Th reader with him visits the badger's setts, and the watches the fascinating chapters in the animal's lif He sees a badger emerge from the sett or earth, scratc himself, romp with his mate, and call out the youn ones.

Knowing the animal as he does, Mr. Neal is in strong position when he puts in a plea for the badge He cannot understand why it excites so great ani mosity, and says that it is a beneficial animal an should be protected, not destroyed. He says tha foxes habitually live in badger setts, and believes th fox is responsible for almost all the lambs presume killed by badgers and found near their setts. Does i kill poultry ? Yes, but rarely. Its food is youn rabbits (it has an uncanny faculty of finding these i the nest), rats and mice, snails, slugs and the like, an it does good by destroying many wasps' nests for th grubs, of which it is passionately fond.

The author is doubtful if the badger hibernates i Great Britain; they were, he says, active in thirty four degrees of frost on February 25, 1947. H mentions that, whereas the gestation period has bee put at twelve months, he considers it to be onl seven months, and gives careful reasoning to suppor his views. When he watches at a sett, the autho does his best to have a tree as a background, for h has found that a badger's sight is poor, and that i relies on its keen scent rather than on its sight t warn it of danger.

The book is illustrated by some beautiful an remarkable photographs; that forming the frontis piece, of a badger at night, is, I imagine, the firs colour photograph ever taken of this animal. Th author gives a map showing the places where th badger is most numerous, where it is scarce, an where it is not found. Is he right to give the Isle o Skye as one of the places where it is unknown ? I seem to remember that it haunts or haunted a smal wood at Kingsburgh in that island.

SETON GORDON

nnual Review of Microbiology

harles E. Clifton, Editor ; Sidney Raffel, Associate ditor ; H. Albert Barker, Associate Editor. Vol. 2. p. viii+532. (Stanford, Calif. : Annual Reviews, nc. ; London : H. K. Lewis and Co., Ltd., 1948.) dollars.

N this, the second volume of a new series of annual reviews, an attempt is made to survey major spects of the vigorous and ever-widening field of nicrobiology. Broadly speaking, the matter pre- nted ranges over the physiology, pathogenicity and enetics of fungi, bacteria, protozoa and viruses ; ut particular themes such as antibiotics, the nature f antibodies, the inheritance of immunity, the mode f action of therapeutic agents, nitrogen fixation, hemical disinfectants and the microbiology of soils, rinking water and sewage, have also received atten- on. In a work which is intended to provide up-to- ate information over a wide field, it would be vidious to pick out particular essays for special ention ; indeed, as some of them run to forty or fty odd pages, it would be difficult to do justice to ny one of them in a short review. The reader is, owever, assured of a wealth and diversity of inform- tion both in the text and in the comprehensive ibliographies.

Differences of opinion doubtless exist as to the ontent and function of annual reviews. Those of he kind under consideration tend to be of the nature f compilations—in the preface the editors refer to the task of compiling critical and, at the same ime, comprehensive reviews". While the several apers included in the annual volume afford an dequate account of what is going on in particular ields, there can be little doubt that they will gain in alue in so far as the attempt is made not only to arry out a paper-to-paper survey, but also to pick ut and emphasize the major contemporary lines of dvance and to summarize briefly the main con- lusions which have been reached or to which the ew discoveries point.

The Failure of Metals by Fatigue

roceedings of a Symposium held in the University f Melbourne, December 2nd–6th, 1946, under the egis of the Faculty of Engineering. Pp. xvi + 505. Melbourne : Melbourne University Press, 1947.) 2s. net.

THE holding of symposia to discuss present views on a particular subject is becoming increasingly opular. Each provides the occasion for pooling vailable scientific knowledge in a particular field, to he great convenience of individual workers on the ubject. The main benefit, however, as Dr. H. J. ough says in his foreword to this volume, is in the rovision "of a spring-board from which valuable esearches will be launched".

Thirty papers read at a symposium in Melbourne n December 1946 are here collected. Two-thirds of he papers are by Australians, but the names of . G. Pugsley, U. R. Evans and H. O'Neil are among hose from Great Britain, with H. F. Moore and G. achs among the contributors from the United States. While the papers are generally of high quality, there is no important new contribution to our basic understanding of the phenomenon of fatigue. The papers give practical examples of the occurrence of fatigue failure in specific service conditions, analyse the conditions promoting reversed stresses of sufficient intensity and suggest methods by which failures could be avoided. Important summaries of our knowledge of the mechanism of fatigue failure are included, and there are papers on testing techniques which, although in some cases on the fringe of the field of fatigue failure, are nevertheless of considerable importance in its understanding or its investigation.

All papers are not of the same high level (for example, the writers on fatigue failures of lead cable sheathing seem inadequately informed on previous British work in this field), but the book is one which justifies the considerable trouble that the promoters of such a symposium must have taken. The absence of an index is deplored.

G. L. Bailey

Inorganic Process Industries

By Prof. Kenneth A. Kobe. Pp. vii+371. (New York : The Macmillan Company ; London : Macmillan and Co., Ltd., 1948.) 30*s*. net.

THIS book is intended to impress on students the importance of following the evolution of an industry and of keeping abreast with modern developments by studying the literature. The first chapter gives a very comprehensive method of studying the literature. The remaining nine might better be entitled "Some Inorganic Industries in the United States", and consist of a series of descriptive articles, each of about 40 pages, on the main heavy-chemical industries. These are presented in a historical manner, contain no references, and do not emphasize new developments. At the end of each chapter a number of articles is listed as a recommendation for students to read. These are almost exclusively of American origin. Except for a few historical references, the subject-matter is confined to the manufacture of sodium and potassium salts, chlorine, sulphuric acid, and nitrogen and phosphorus compounds in the United States ; and the book can scarcely be expected to appeal to British readers, in spite of an admirable set-up, clear diagrams and good printing.

H. E. Watson

The Works of George Berkeley, Bishop of Cloyne

Edited by Prof. A. A. Luce and Prof. T. E. Jessop. (Bibliotheca Britannica Philosophica.) Vol. 1 : Philosophical Commentaries, Essay towards a New Theory of Vision, Theory of Vision Vindicated. Edited by Prof. A. A. Luce. Pp. viii + 280. (London and Edinburgh : Thomas Nelson and Sons, Ltd., 1948.) 30*s*. net.

THIS first volume of the new complete edition of the works of Berkeley is most welcome and is a handsome well-produced book worthy of its subject. Fraser's editions of 1871 and 1901 have been useful, but have some serious defects. Fraser discovered the notebooks containing Berkeley's "Philosophical Commentaries", but failed to see that they had been bound together in the wrong order. His transcription was not always accurate. Prof. Luce's magnificent edition of 1944 put right these defects and provided invaluable notes. He here reprints the "Commentaries" in handier form with shorter notes, sufficient for explanatory purposes. The "New Theory of Vision" never presented serious textual difficulties ; but Fraser did not distinguish properly the alterations made by Berkeley in his life-time and does not appear to have used the last version. Prof. Luce reprints this fourth and last edition, indicating all alterations. In his introduction, while stressing the permanent value of this work of Berkeley, he mentions a point often forgotten, namely, how much it owed to the influence of Molyneux.

The "Theory of Vision Vindicated" is here for the first time available in a really intelligible form; Fraser unfortunately used a very imperfect version that had been printed by Cowell. This short work of Berkeley is valuable because it effectively corrects the false impression sometimes produced on modern readers of the "New Theory of Vision". That was the first thing Berkeley published; it embodied a strictly technical discussion of the processes of sense perception; it was a necessary preliminary to his philosophy, but did not require its explicit statement. Had he introduced the novel conceptions and the terminology of his "Principles", to be published in the following year, his first readers would have been confused. Berkeley's care for the difficulties of his contemporaries created difficulties for later readers. These, knowing the views of the "Principles" and finding apparently contrary views in the "New Theory", have often accused Berkeley of inconsistency. Anyone who takes the three works in this volume together will see that there is no inconsistency. A. D. R.

Weather Forecasting

By Instructor-Comdr. S. W. C. Pack. Pp. 192+8 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1948.) 25*s*. net.

INSTRUCTOR-COMMANDER S. W. C. PACK is concerned more with the fundamental bases of synoptic meteorology than with the actual details of weather forecasting. As a grounding, his book is comprehensive, beginning with the structure of the atmosphere and, briefly, meteorological instruments, and continuing with a good deal of climatology, which is an essential background to all weather forecasting. Incidentally, the thermometer at Blackadder which recorded a minimum of −23° F. was *not* conventionally exposed. The chapter on "Fronts" and the development of depressions is on the usual lines; but wind in relation to pressure gradient is more clearly demonstrated than is usual in text-books. The most detailed and best part of the book is the treatment of adiabatic changes, dry and saturated, and the discussion of the tephigram and its uses in determining stability or instability; this should make a difficult subject clear to most students, as should also the later chapter on the variation of wind with height. The chapter on analysis and forecasting covers only eleven pages and is disappointing; there is no actual example of the analysis of a chart, either at ground-level or in the upper air. The book is well illustrated with photographs and clear diagrams, but seems high-priced for its size.

A Statistical Analysis of Advertising Expenditure and of the Revenue of the Press

By Nicholas Kaldor and Rodney Silverman. (National Institute of Economic and Social Research, Economic and Social Studies, 8.) Pp. xiv + 200. Cambridge: At the University Press, 1948.) 15*s*. net.

THIS book arose from a proposal made to the National Institute by the Advertising Association that an impartial inquiry should be made into the economic effects of advertising. The authors have carried out a very difficult task with extreme competence and are to be complimented particularly on their method of presentation. The main emphasis has been placed on the period 1934–38, with the result that we now have a comprehensive statistical survey of advertising expenditure in the United Kingdom for the pre-war years. Figures relating to the revenue of the Press extend to more recent years—up t 1944.

This is a most interesting example of what can b achieved when a research body has the full co-operation of professional and trade associations, togethe with the support of individual firms. Analyses of thi nature will be of particular interest to the historia of economics, and it is to be hoped that they will b repeated at regular intervals in the future. The mai findings are clearly summarized in the first part o the volume in order to save the time of the les statistically minded reader, and the authors hav wisely refrained from detailed comment, leaving th facts to speak for themselves. The second part i devoted to a detailed description of the methods b which the various estimates have been made Consequently, the book can be strongly recommende to students of economics, not only for its subject matter but also for the insight which it gives int methods of approach.

In passing, it is interesting to note how handicappe the investigators were in the absence of a census o distribution. One small criticism is that man references are made to sources of information. Whil most of these are to be found among the index, i would be helpful to the specialist reader if in subsequent edition they were to be listed in bibliography. E. C. DANIELS

Le Bartonien du bassin de Paris

Par L. et J. Morellet. Pp. viii + 437. (Paris Service de la Carte géologique, 1948.) N.p.

LUCIEN MORELLET, whose death occurred i 1945, was one of the many distinguished Frenc geologists who have devoted their attention to th richly fossiliferous Eocene deposits of the Paris Basin In collaboration with his brother, Jean Morellet, h studied especially the calcareous algæ, on which h was recognized as a world-wide authority, and th Parisian Eocene strata above the Lutetian. Th results of more than forty years of observations and collecting by the two workers on this latter subjec have now been edited and arranged by M. J. Morellet and issued as a memoir of the Service de la Cart Géologique.

This study lists and describes in detail, with copiou fossil lists, almost all sections in the Paris Basin 'Etage Bartonien', many of which have been long since obscured, discusses the significance of the fauna and flora with regard to palæogeography and climate, and reviews the history of the classification and correlation of strata at this horizon. In coming to a decision on this vexed question, the authors are wisely tolerant, recognizing the difficulties inherent in the study of these variable strata, and admitting frankly that it is unfortunate that 'Bartonien' was initially proposed for Parisian strata and not for the familiar Barton Beds in England. If it is too much to expect that all students of the Eocene will agree with their 'Bartonien' covering all Eocene beds above the Lutetian in France, and ranging in England from the base of the Upper Bracklesham to the top of the Lower Headons, the supporting evidence and common-sense nature of the final decision for a single stage are obvious, even if the name retained is unwise.

Meanwhile, the volume is a magnificent detailed record of a type-area invaluable to all students of the older Tertiary, and a fine memorial to the life-work of L. Morellet and the long collaboration between the two brothers; M. J. Morellet is to be congratulated. G. F. E.

STRUCTURE AND ACTIVITIES OF THE BACTERIAL SURFACE

ON April 20 the Society for General Microbiology held a symposium on "The Nature of the Bacterial Surface". Seven contributions and two urveys by the chairmen had been printed and irculated to members of the Society before the meeting. On the assumption, which proved to be well founded, that these had already been read by hose attending the symposium, most of the time of he meeting was spent on discussion. Argument had o be restrained rather than promoted by the chairmen, and it ranged over a wide but relevant field; although the meeting was extended beyond the time arranged, it finished with several members still wishing to speak.

There was general agreement on many subjects. Several speakers pointed out that the microscopically visible capsule is dispensible and that there are no definite divisions between the successive layers by which the cell is surrounded; these views were not controverted. Opinion varied over the extent to which electron-micrograms give direct evidence about the original material that is being examined; but, after some years of rather uncritical acceptance of electron-micrograms at their face value, it was refreshing to find that there was general awareness that changes can take place during the preparation, drying and shadowing of a specimen. Finally, the suggestion that the macroscopic properties of films, fibrils and threads are not an infallible guide to the properties of similar, but much smaller, structures, may be mentioned. No one postulated new properties of matter; but there was agreement that we should beware of arguments based on the extrapolation of the conventional properties of matter to bacterial appendages that may be only one-thousandth the size of structures that have already been thoroughly investigated.

Evidence coming from the serological properties of bacteria, and of antigens prepared from them, was considered by W. T. J. Morgan. He argued that the failure of a serological reaction does not necessarily mean that the structure which should have reacted is placed deeply in the organism; it could be near the surface but in a state of chemical combination that keeps it from reacting, or it could be surrounded by larger amounts of a more reactive antigen. In discussion, C. M. Chu stressed the importance of a serological study of the bacterial residue left after the mild extraction procedures advocated by Morgan. In this way more light might be thrown on the actual location of antigens which appear to lie on the surface.

A comprehensive picture of the chemical processes involved in Gram-staining, in the synthesis of capsular polysaccharides, and in the action of the pneumococcal transforming principle, was presented by M. Stacey. Harriett Taylor criticized this picture with logic and pertinacity. Stacey suggested that the deoxyribose nucleic acid, the presence of which promotes capsule formation by non-capsulated pneumococci, is contaminated by traces of capsular polysaccharide, and that this, by analogy with other cases where polysaccharide is needed as a starter for polysaccharide synthesis, is the effective substance. She agreed that the deoxyribose nucleic acid, like all large molecules, is probably contaminated, but looked on the capsular polysaccharide as one of the less probable contaminants. Stacey's suggestion that the Rough pneumococci have less nucleic acid on their surfaces than the Smooth, and that roughness results from growth under deficient nutritional conditions, she likewise emphatically rejected. There were repercussions of this disagreement in the discussion after Harriett Taylor's paper on pneumococcal transformation. It seems to originate in the orthodox chemist's unwillingness to accept the enormous number of specific nucleic acids called for by some biological evidence. Until we know something of the minimum size of these postulated active nucleic acids, and of the effect which a change in nucleotide sequence has on specificity, this unwillingness seems premature. It is easy to get the required number of isomers if every difference in sequence is significant. In Taylor's paper, examples had been given of deoxyribose nucleic acids made from different strains of pneumococcus that are chemically indistinguishable but differ biologically.

Work with the pneumococci suggests that the bacterium can at one time have only one type of capsule and one type of transforming principle—as if there is a single locus which can be occupied by only one type of transforming substance. A somewhat different form of 'exclusion principle' was described by D. McClean. Streptococci can have either hyaluronic acid capsules or they can secrete hyaluronidase, but not both. The addition of hyaluronidase to capsulated organisms decapsulates them, whereas the addition of hyaluronic acid to some streptococcal cultures stimulates the adaptive formation of hyaluronidase. We have here a fascinating field for studying the interplay of the biochemical factors on which the morphological and other properties of an organism depend.

Peter Mitchell considered the properties of the osmotic barrier. He was more concerned with what the barrier does and how it does it than with what it is made of and how thick it is. He showed that for many substances it cannot be regarded as a passive filter, acting by virtue of differences in pore size or partition coefficient, and suggested mechanisms by which osmotic work could be done in the barrier. In discussion, the problem was skilfully defined by K. A. Bisset, who contended that there is no reason to postulate any thickness for the osmotically active layer. In his view it may well merge with the cytoplasm of the cell and so have no defined inner surface.

The reaction between bacterial viruses and the cell involves a series of changes in the bacterial surface; T. F. Anderson discussed the conclusions that can be drawn from this line of evidence. His own work and Schlesinger's shows that the observed number of effective collisions between bacterium and virus agrees with the number theoretically to be expected with particles of these sizes. This means that, in spite of the specificity of the action, nearly every collision is effective. He suggested that this could come about if the first connexion is with a plastic structure on which subsequent rearrangement can take place or which, if this fails, can break off from the organism. With his group of viruses, so long as host and virus have not been deliberately inactivated, absorption only takes place on to cells capable of sustaining virus multiplication. The surface carries "frank, specific displays of its range of suitability as a host for the viruses to which it is sensitive". In the introduction, N. W. Pirie had stressed the lack of evidence that viruses penetrate the bacterial cell wall; their multiplication on, rather than within, the wall would be compatible with Anderson's evidence. As often happens when viruses are under consideration, the discussion took on a slightly metaphysical tinge. Felix urged a return to Bordet's view that bacterial viruses are fragments of the bacterial cell; but Anderson, because of the absence of serological relationships between the viruses and host cell constituents, saw no advantage in this hypothesis. A lysin can be made by ultra-violet irradiation of some viruses; A. Pirie asked if this should be looked on as an enzyme attacking a substrate in the cell surface or as an activator for the autolytic mechanism already present in the surface. Anderson said he did not know how often a molecule had to do the same job, without being destroyed, before it should be called an enzyme. There is no evidence that the substances postulated in these processes act more than once.

The part of the bacterium that is responsible for its mechanical integrity was only discussed briefly. I. M. Dawson showed electron-micrograms of the rigid cell wall made by centrifugal fractionation of a suspension of staphylococci that had been shaken with glass beads, and J. Smiles described the elastic properties of the membrane surrounding various organisms and of the septa which form before or during cell division. In different organisms these structures have characteristically different properties when subjected to stresses by flow of the medium or by drying. The general properties of these membranes were surveyed by E. T. C. Spooner from the point of view of the bacteriologist, but nothing was said about their chemical nature.

The last paper to be discussed was by A. Pijper, on bacterial motility, and this subject was also the main theme of A. A. Miles's introduction from the chair. Pijper contends that bacteria move by virtue of an undulatory or corkscrew movement of their bodies, and that the flagella are wisps of slime trailing in the medium. He does not deny the existence of flagella, but looks on them as the consequence rather than the cause of motility. Observations on living bacteria under dark-ground illumination with sunlight give the main evidence for this point of view, and some of the phenomena were illustrated by a cinematograph film. Here it appeared that the direction of movement of the body is the first thing to change, and that it is only after this has happened that the flagella move round to the rear of the moving organism. Pijper's view was hotly contested. T. Y. Kingma Boltjes thought the mechanics very improbable and preferred the conventional interpretation of motility. A. Fleming confessed himself nearly convinced, but found his own observations on the rotational movements of *Proteus* grown in the presence of penicillin more nearly compatible with the concept of active flagella. This movement only takes place when the specimen is illuminated, and it appears that, when the light is turned on, flagellar movement precedes movement of the organism. The uniformity of flagella in electron-micrograms, and especially the fact that in one organism (unclassified) two distinct sizes are seen, together with the constancy with which the same number of flagella are seen in the same place on the members of one species, seemed to A. L. Houwink to rule out the trailing slime hypothesis. A similar attitude was taken by W. van Iterson, who showed electron-micrograms of flagella apparently connected with the protoplast or with granules. Their formation from these structures would suggest that they are not formed by the casual streaming away of surface slime but are a specific extrusion. What is known of the chemistry of flagella makes such an origin probable. Conclusions about their origin do not, however, radically affect the problem of flagellar movement and, although Pijper's interpretation contains undoubted difficulties, no clear refutation of it was forthcoming.

It was generally agreed that this symposium was valuable, and that much of its value depended on the 'preprinting' of the main contributions. This technique is already used regularly by some societies; but its expense is bound to keep it from being adopted widely. It may therefore be legitimate to argue briefly the national economics of such meetings. Three hundred people attended this one, and at least two hundred of them were paid directly or indirectly out of public funds. The average of their salaries is certainly not less than £2 per working day. For an all-day meeting some are away for more than a day and many get travelling expenses. The hidden cost to the community of such a meeting is £500 at the lowest estimate, quite apart from the ordinary cost to the society. This expense is fully justified; but it is important to recognize that it is there, and to ensure that the best use is made of the time and money spent. If, by 'preprinting' the papers, we can increase significantly the value to the participants of the time spent in a meeting, it seems not unreasonable that the cost of 'preprinting', £100–£200, should be borne by public funds.

N. W. PIRIE

NATURAL PRODUCTS IN THE BRITISH COLONIAL EMPIRE

THE second report of the Colonial Primary Products Committee*, dated January 1949, consists mainly of a series of commodity studies, to which is appended a note by the Imperial Institute on distillation of essential oils, describing inexpensive plant for this purpose. Recommendations of the Committee in regard to groundnuts are discussed elsewhere (p. 889 of this issue); in regard to oil-palm products, the Committee recommends the introduction of a superior grade to encourage the production and sale for export of an oil suitable both for edible and technical purposes. The Committee considers that for coconut products a long-term assurance is of the first importance; but of other edible oils and oil-seeds yielding edible oils produced in the Colonial Empire, kapok seed, neem oil and dika fat are unlikely to be of use for edible purposes, special encouragement of sesame is not recommended, and of the minor oil-seeds only cottonseed and illipe nuts appear worth encouraging. The best hope of increased production of soya beans in the near future appears to lie in East and Central Africa, and the Committee hopes that the assured market will stimulate increased production there, and that departments of agriculture will pursue their variety trials. It suggests that if the large-scale trials of sunflowers as a rotation crop in Tanganyika prove satisfactory, consideration should be given to growing the crop extensively elsewhere. It also considers that every effort should be made to increase Colonial production of drying oils to reduce the gap between sterling demand and sterling supply, and hopes that the present acreage of linseed in Kenya will be maintained, if not extended. Attention is also directed to the considerable possibilities of the candlenut tree, *Aleurites moluccana*, as a native-grown permanent tree crop, and to the desirability of establishing trial plantings over a wide range of conditions. It is suggested that the Colonial Products Research Council should undertake decortication trials with samples of nuts with the view of evolving a suitable decorticator for Colonial conditions. Production in the Empire of tung oil is centred in Nyasaland, and if the yield from the Colonial Development Corporation's project in the Vipya Highlands materializes, together with production in the Southern Province in eight or ten years, much of the United Kingdom's demand should be met. Trials with the cultivation of high-yielding strains of castor giving non-scattering seeds are recommended, and also further trials of rubberseed oil and the cultivation of *Tetracarpidium Conophorum*. Encouragement of the cultivation of perilla, niger seed, chia oil, ongokea or isano oil, poy-ok oil and tee-seed oil is not recommended for reasons given.

---

* Colonial Office. Colonial Primary Products Committee. Second Report, January 1949. (Colonial No. 238.) Pp. 60. (London: H.M. Stationery Office, 1949.) 1s. net.

The three main kinds of starch produced in the Colonies are arrowroot, sago flour and tapioca starch. There is every reason to increase the growing of arrowroot, and it is hoped that two grinding mills of an improved type will permit an increased yield to be obtained in St. Vincent from the root. Growing in Grenada is also proposed; but no unqualified recommendation is given for increased production of cassava for starch.

The Committee considered in detail the production and marketing prospects of a considerable number of essential oils; it recommends, however, stimulation or exploration of production only for cajuput, cananga and ylang ylang, eucalyptus, geranium, juniper, lavender, neroli, patchouli, peppermint, petitgrain, spearmint, thyme, vetiver or 'cus-cus' and wormseed. Of the citrus oils, the production of a better quality of grapefruit oil should be encouraged. New production of citronella oil would have to compete in well-established markets, and future production of cloves and clove-stem oil in Zanzibar and Pemba is likely to be affected by a serious outbreak of the 'sudden death' disease.

With regard to timber, the Committee considers that while it will be a long time before softwood production can be developed on a large scale, the hardwood exports of British Colonial territories are capable of very substantial expansion; but maximum production cannot be secured without a great improvement in the supply of machinery, in communications and increased staff. There is much scope for research in sylviculture and conservation, and especially on utilization. Maximum production depends on such matters as the increased conversion of timber from the log, particularly of secondary timbers, to economize on the freight of logs by transporting them in semi-processed form, and the development of veneer and plywood manufacture in the Colonies.

In regard to paper pulp, there are many products from which paper pulp of varying qualities can be made, but the number of economic materials is reduced by considerations of homogeneity, accessibility and certainty of supply. While there are a number of lines of inquiry, particularly into eucalyptus and wattle, which can be profitably pursued, the Committee believes there is at the moment no project which can be confidently recommended as a practical proposition. Reviewing the position of tanning materials, the Committee considers that owing to the war-time consumption of quebracho for fuel and the serious spread of disease among the chestnuts of South America, there is risk of a world shortage of vegetable tanning materials in the next twenty years if alternative sources of supply are not developed. Wattle is the most promising source of such materials in Colonial territories, and its cultivation should be encouraged, particularly on the highlands of East and Central Africa. The Committee also estimates that present schemes of development could increase Colonial production of tobacco by about fifty per cent, if the equipment, skilled labour, finance and fertilizers are forthcoming. While, however, the Colonies will continue to supply an appreciable part of the United Kingdom's requirements of pipe tobacco, they contribute to a very limited extent only to those of cigarette tobacco.

The Committee has also considered Dr. C. F. Hickling's report on "The Production of Fish in the Colonial Empire", since issued as Colonial No. 237*; it regards this report of the Fisheries Adviser to the Secretary of State for the Colonies as expressing adequately its own views. Dr. Hickling outlines the training now being given to some twenty-one fishery officers, and emphasizes the importance of studying methods of fish preservation with a view to their improvement by research. A fish preservation research officer is to be attached to headquarters, who will advise Colonial Governments as well as conduct research. A large sample of salted fish and of shark has been sent to the managers of the East African groundnut scheme for evaluation; and biological research on the fish taken in the survey of the Mauritius and Seychelles area of the Indian Ocean is also being carried out, and a biochemist has joined the survey. A West African Fisheries Research Institute is being established at Kessy Dockyard in Sierra Leone, and the scheme provides for long-term research on the productivity of the sea off West Africa. In Uganda, research is provided by the Fisheries Research Station at Jinja, and plans are being drawn up for a fisheries research station in Northern Rhodesia. Research in the South-East Asia region is to be provided for by a large research station, preferably at Singapore, which with its research vessel should cover the area from the Andaman Islands to North Borneo. A scheme has been approved for a centre for research and training in fish culture in Penang, Malaya.

Generally, it is considered that while there is considerable scope for increasing the Colonial production of fish, such increased production will be absorbed by the Colonies themselves, and except from the Gulf of Aden, Hong Kong and the Mauritius–Seychelles areas, surplus for export is unlikely. Increased production depends largely on the application of mechanized methods, which is hindered by difficulties in obtaining ships, equipment and trained staff. Although these deficiencies are being overcome, Colonial Governments must be prepared to make the necessary expenditure. Reference is also made to the development of by-products such as shark-liver oils, isinglass, and alginic acid and agar-agar from seaweeds.

CHINESE CERAMIC GLAZES

WITH SPECIAL REFERENCE TO THOSE DERIVED FROM COPPER*

By A. L. HETHERINGTON, C.B.E.
Honorary Secretary of the Oriental Ceramic Society

THE Chinese potters employed for the colouring of their glazes prior to the fourteenth century two metals, and two only, for the great majority of their effects. Those two metals were iron and copper, and both continued to be used extensively in subsequent times. But other metals then came into wider use as well, notably cobalt for the well-known blue and white wares, and, later still, gold for the familiar group known as *famille rose.*

The Chinese potter first used copper on an extensive scale for colouring his glazes in the T'ang dynasty, A.D. 618–906. In that dynasty the potter produced a variety of green glazes from cupric oxide which are relatively easy to produce. In the subsequent periods, green glazes were made in profusion and in a variety of shades. While there is not much evidence of copper greens in the succeeding Sung dynasty—960–1279, or, say, from the date of the crowning of Otto I as Holy Roman Emperor to that of the signing of Magna Carta—they were made in great variety in the Ming and Manchu dynasties; that is, during 1368–1912, or from the date of Chaucer to modern times.

Cupric oxide in a glaze gives rise to a range of colour from blue to green, and these colours are accounted for by the varying amounts of cupric oxide present and especially by the nature of the glazes in which it is incorporated. The more basic the glaze, the greater will be the tendency to a blue colour; and the more acid the glaze, the greater will be the predominance of the green.

Cupric oxide dissolves in a glaze formed of potassium silicate or of sodium silicate, or a mixture of the two, to give a blue colour at about 1,300° C. If alumina is present as well, there is a considerable tendency for the blue to turn to green. If lead is present, the potash lead silicate glaze is blue, but tends to green if the lead is in excess. To retain a blue colour, the alkaline constituent must be relatively high, and if alkali is lost by volatilization, the glaze becomes acidic and green will result. But the alkali content must not be too high, since then the glaze becomes unstable and is liable to break down on exposure to a humid atmosphere.

The blue glazes from cupric oxide were not mastered until the Ming and Manchu dynasties. It was, and is, a difficult colour effect to produce. The greens from copper are relatively simple in comparison.

The fact that ceramic production in China from the Ming dynasty onwards was mainly centred in the ceramic metropolis of Ching-tê-chên, where an enormous number of operatives were employed under imperial patronage, no doubt accounts for the greater technical skill responsible for this and other glaze effects.

Under reducing conditions, copper in a glaze produces the range of reds which are familiar; the famous *sang de bœuf* and the peach-bloom glazes, as well as a variety of other shades of red, are due to copper. These copper-red glazes are brought about by the reduction of cupric oxide to the metal itself in a finely divided colloidal condition. In order to produce a clear blood-red glaze, not more than one half of one per cent of copper must be present. If more than that is put into the glaze, the colour becomes opaque, with a red sealing-wax appearance.

The chemistry of the copper-red glazes was established by Dr. J. W. Mellor and may be briefly summarized as follows. The red colour is due to the even aggregation of finely divided colloidal particles of copper to form a band in a certain portion of the glaze. The formation and maintenance of this red band are assisted by the presence of iron (or tin) oxide. The effect is brought about by a reducing atmosphere at the outset, and the glaze is finished off in an oxidizing atmosphere.

Colloidal copper, when in a very fine state of division, is yellow; in a slightly less fine state it is red, and when the particles are slightly larger still, they look blue by transmitted light.

At the outset, under strong reducing conditions, the cupric oxide is reduced, and any iron present is reduced to ferrous oxide. The atmospheric oxygen, on its introduction, attacks the molten glaze and oxidizes the topmost layer, converting the copper to cupric oxide. As a result, the surface layer of a copper-red glaze is colourless, or faintly green from the small amount of copper in the glaze. Below that layer the oxidizing action is relatively slight, and a layer of yellow can generally be seen consisting of finely divided particles of colloidal copper. Below that layer there is no oxidizing action on the part of the atmospheric oxygen, and a red band of slightly larger sized colloidal particles appears, below which is a narrower band of blue particles of slightly larger size still. The iron oxide present helps to stabilize the colloidal copper and keep it dispersed to form and maintain the red band.

The famous peach-bloom glaze is a variety of the *sang de bœuf* in which the attack of the atmospheric oxygen is allowed to continue longer. As a result, the red colour is diminished to a pinkish-red with the blue particles showing faintly below it. Sometimes in these peach-bloom glazes, which are difficult to produce in perfection, green spots appear. These green spots are due to colloidal particles of copper forming small aggregations by flocculation. These are oxidized to cupric oxide by the atmospheric oxygen and immediately dissolve in the glaze to give the characteristic green of cupric oxide.

An on-glaze copper-red glaze which is entirely different from the in-glaze effect can be produced by the formation of a copper aerosol as a thin layer of copper particles near the surface of the glaze.

---

* Summary of a Wednesday Evening Discourse at the Royal Institution, delivered on May 18.

OBITUARIES

Mr. F. N. Ashcroft

IT was with deep regret that his many friends heard of the sudden death in London on April 4 of Frederick Noel Ashcroft. He had just completed a great task as honorary treasurer to the Eighteenth Session of the International Geological Congress. His careful attention to detail and his devotion to the work contributed largely to the great success of the Congress. He was publicly thanked for his work at a meeting of the Geological Society on March 23. Ashcroft brought to this task a wide knowledge of business accounts. He had been honorary treasurer of the Geological Society of London during 1929–47, and of the Mineralogical Society during 1920–42; also he was a managing trustee of the Geologists Association and of the Mineralogical Society. He was also honorary treasurer and vice-chairman of the Metropolitan District Nursing Association, with which he had been connected as a member of the Executive Committee since 1920. He was president of the Mineralogical Society during 1942–45, and at the time of his death he was its foreign secretary; he was also a vice-president of the Geological Society.

To his many friends in London, it must have seemed that Ashcroft's whole life was devoted to the financial affairs of these societies; but he was first and foremost a mineralogist, and his lasting memorial in the years to come will be the two superb collections of minerals which he had presented, or has now bequeathed, to the British Museum (Natural History), documented with an accuracy which few others would have had the patience and knowledge to achieve.

Ashcroft went from Rugby to Magdalen College, Oxford, in 1897, and gained a first in honours chemistry in 1901. He worked at Tübingen in 1901 and later at University College, London, in the Department of Organic Chemistry, and published a paper in the *Journal of the Chemical Society* in 1907. At Oxford he had also studied mineralogy under Miers, from whom, like so many others, he acquired an interest in minerals which decided the main lines of his future work. Ill-health prevented him from undertaking any full-time work; but Ashcroft could not be idle and he devoted himself to the study and collection of minerals, working partly in the Mineral Department of the British Museum and partly in the Chemistry Department of University College, London, where J. Norman Collie, himself a fair mineralogist, was professor. At first specializing in zeolites, Ashcroft brought together in the course of ten years or so a notable collection of these minerals from all over the world. In 1914 he presented the bulk of this collection to the British Museum, retaining only his Irish specimens, intending to continue publishing accounts of these when time allowed. It was well after the conclusion of peace, in 1920, that Ashcroft turned his attention to the minerals of the Swiss Alps. Here he set out not merely to acquire fine specimens, but also to record the exact localities where each was found and to collect representative specimens of all the minerals associated in each locality, thus bringing together all the data for a complete study of the distribution and paragenesis of the minerals. Carrying a heavy camera, hammers and chisels, he went round the recently worked localities with the mineral collectors on his annual visit to Switzerland, collecting, noting and photographing. He was an expert photographer and his catalogue is profusely illustrated by photographs of his own taking. Many of these were used to illustrate "Die Mineralien der Schweizeralpen" by Niggli, Koenigsberger and Parker, with whom Ashcroft collaborated. Others appear as plates in Arthur Holmes's "Principles of Physical Geology".

It was an education to accompany Ashcroft on one of these visits to the Alps and to see him at work. He had gained the affection of mineralogists and mineral collectors all over Switzerland, and if they were sorry to see their best specimens being taken to London year after year, they forgave him for the big kind-hearted enthusiast that he was. His collecting trips were usually followed by a holiday with his family. He had married in 1904 Constance Muriel, daughter of J. C. Im Thurn, and had two sons and two daughters. He was devoted to his family and very proud of his grandsons, and they were all devoted to him.

He had many friends among mineralogists at home and abroad. He was a member of the Swiss Mineralogical Society and of the Museums Association as well as of the other societies mentioned, and he was a charter member of the Mineralogical Society of America. W. CAMPBELL SMITH

Mr. Edward Heawood

MR. EDWARD HEAWOOD, emeritus librarian of the Royal Geographical Society, died on April 30, in his eighty-fifth year.

Heawood was attracted to geography through an early interest in natural history, and the great narratives of exploration. After taking his degree in classics at Cambridge, he received instruction in surveying and other field studies at the Royal Geographical Society, and spent two years in India working on a settlement scheme among the Santals in the Bengal Duars. On his return, he joined the staff of the Society, assisting with the newly established *Geographical Journal* and in the library. On the retirement of Dr. H. R. Mill in 1901, he succeeded him as librarian, an appointment which he held until 1934. During these years the Society's Library expanded considerably under his guidance, particularly in its collections of foreign geographical periodicals and of early geographical texts and atlases. His extensive knowledge of the literature of geography, aided by an exceptional memory, was readily placed at the disposal of students.

His special interest was at first in African geography and in the history of exploration generally. His "History of Geographical Discovery in the 17th and 18th Centuries", published in 1912, is a careful and comprehensive study which remains the best general guide to that period. This line of study led naturally to that of the cartographic sources, to which his attention was increasingly given, until he had established a widely recognized reputation as an authority. Most of his work is to be found in the *Geographical Journal*, in numerous notes and reviews as well as in longer papers, but two important memoirs appeared as separate publications of the Royal Geographical Society: "The Map of the World on Mercator's Projection by Jodocus Hondius, 1608" (1927) and "English County Maps in the Collection of the R.G.S." (1932). A further development of this work, which was perhaps his most individual contribution, was his extensive study of water-marks used by paper-makers, which threw much light on the sources and distribution of paper, in addition to its use in dating maps and other documents. He concentrated upon marks on paper used in England, filling in the gap left by Briquet and other Continental writers. His first article, in the *Geographical Journal* of May 1924, was followed by others in *The Library* of 1930, 1931 and 1948. On the day of his death he had been at work on an index to a selection of his tracings of marks, which is to be published in Holland.

Heawood received the Research Medal of the Royal Scottish Geographical Society in 1933, and in the following year the Victoria Medal of the Royal Geographical Society. For many years he was treasurer of the Hakluyt Society, and had been recorder of Section E (Geography) of the British Association. G. R. CRONE

Prof. J. Velenovský

The death occurred on May 7 of the Czechoslovak botanist, Prof. Josef Velenovský, at Mnichovice, near Prague; he was ninety-one years of age.

Born at Čekanice, a small southern Bohemian village, on April 22, 1858, Velenovský was a student of Sachs and Čelakovský, and in 1885 he obtained a post at the Charles University of Prague. In 1898 he succeeded Čelakovský as professor and continued teaching for forty-two years until he retired in 1927. It was during his professorship that the present Botanical Institute was erected, and for many years Velenovský was also director of the botanical gardens attached to the Institute.

During his career he wrote at least four hundred different publications, including a number of textbooks and treatises that served successive generations of Czech students. His early researches related to phytopalæontology, especially the fossil flowering plants occurring in Bohemian chalk (1882–87). His studies in this field were published in a work of five volumes, "Flora Cretacea Bohemiæ".

Later, Velenovský made a detailed systematic study of fungi, and he is probably best known in Great Britain for his "České Houby" (Bohemian Fungi), first published between 1922 and 1926 and revised in 1946. The book is noteworthy for its illustrations. He spent many vacations in the Balkans, and one outcome was his "Flora Bulgarica" (1891), the standard flora for the country and which he afterwards brought up to date with addenda. Later work was mainly concerned with studies of the bryophytes (1897), though he contributed to many branches of systematic botany, and as late as 1947 he was engaged upon "Novitates Mycologicæ Novissimæ", which is being published by the Czechoslovak Botanical Society.

After retiring, Velenovský maintained his scientific interests and also wrote some philosophical and historical essays. One of these was for the jubilee publication in 1932 of the Czech Naturalists' Club, of which he was the oldest living member. Velenovský received many Continental and some British honours.

J. G. F. D.

NEWS and VIEWS

Plant Pathology Laboratory: Mr. W. C. Moore

Mr. W. C. Moore has been appointed to the post of director of the Plant Pathology Laboratory of the Ministry of Agriculture and Fisheries at Harpenden, on the retirement of Mr. C. T. Gimingham. Mr. Moore received his early education at Sexey's School, Bruton, whence he joined Trinity College, Cambridge, in 1919, becoming a major scholar in 1921. After graduation he remained at the Cambridge Botany School to participate in the investigations on silver-leaf disease of fruit trees then in progress. He joined the staff of the Plant Pathology Laboratory in 1925 as assistant in mycology, becoming mycologist in 1944 and deputy director in 1948. During his official career he has been in the closest touch with other British plant pathologists, especially those in the advisory services, whose work he has greatly fostered and assisted. Not infrequently he has suggested problems for investigation. Latterly, he has been responsible for editing a series of valuable reports on the incidence of plant diseases in England and Wales. He has taken a principal part in preparing the excellent leaflets on the diseases of economic plants issued by the Ministry. Notwithstanding heavy administrative duties he has continued his own researches (chiefly on little-known diseases), the results of which have been mostly published in the *Transactions of the British Mycological Society*. Noteworthy, too, is his bulletin on the "Diseases of Bulbs", published in 1939, which is an important contribution to plant pathological literature. He was president of the British Mycological Society in 1941 and of the Association of Applied Biologists in 1947–48. Mr. Moore is a keen gardener, and the practice of this art has been not without influence on his career as a plant pathologist.

Geology at Sheffield: Prof. Leslie R. Moore

Dr. Leslie R. Moore, at present reader in stratigraphy in the University of Bristol, has been appointed to the Sorby chair of geology in the University of Sheffield, in succession to Prof. F. W. Shotton (see *Nature*, 155, 664; 1945), who has been appointed to the chair of geology at Birmingham. It is expected that Prof. Moore will take up his duties at the opening of the new session in October next. After taking his first degree at the University of Bristol in 1934, Dr. Moore carried out postgraduate work on "The Sequence and Structure of the Somerset and Gloucestershire Coalfields", for which he was awarded the Ph.D. degree. His first university appointment was in the Department of Geology, University College, Cardiff; later he became research fellow and lecturer in geology in the University of Glasgow, before returning to Bristol as reader in stratigraphy. Dr. Moore's researches have dealt especially with the geology of coal measures and oil shales and are notable for the employment of new techniques, to the development of which he himself has made substantial contributions.

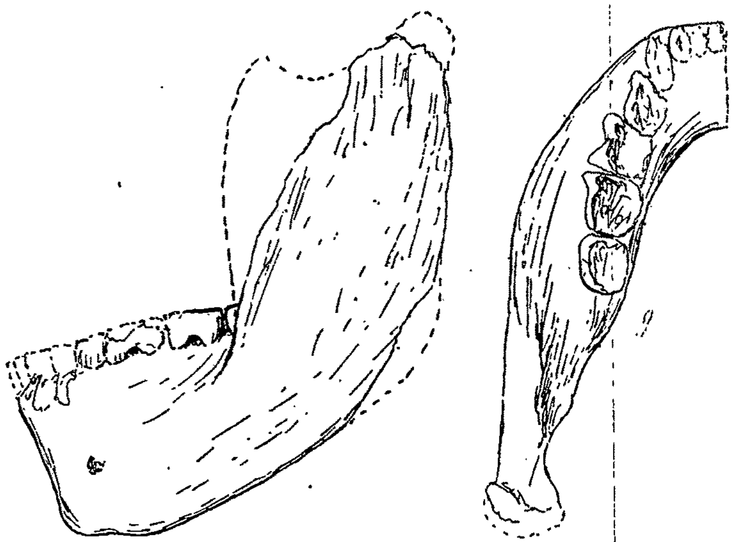
New Grassland Research Station at Hurley: Dr. W. Davies

Dr. William Davies, at present director of the Grassland Improvement Station of the Ministry of Agriculture and Fisheries at Drayton, Stratford-on-Avon, has been appointed director of the Grassland Research Station for Great Britain. This new station is being established at Hurley in Berkshire and is being amalgamated with the Drayton Station under the new Governing Body, the formation of which was recently announced. Dr. Davies was a student at the University College, Aberystwyth, under Sir George Stapledon, and was later a member of staff at the Welsh Plant Breeding Station at Aberystwyth. On the establishment of the Grassland Improvement Station, he was appointed assistant director, and became director in 1946 on the resignation of Sir George Stapledon. Dr. Davies has conducted researches and surveys in New Zealand, Australia and the Argentine. A survey of the grasslands of England was made in the years 1938–40, and the results were published in 1941. More recently, Dr. Davies has visited several African countries and carried out grassland surveys there.

Jaw of the Ape-Man *Paranthropus crassidens*

Dr. Robert Broom, of the Transvaal Museum, Pretoria, who is now on a visit to Great Britain, during which he has received the Wollaston Medal of the Geological Society of London awarded to him this year, writes as follows:

"In November 1948, we found at Swartkrans while excavating a new site in co-operation with the California University Expedition a lower jaw with very large molar teeth. I called it *Paranthropus crassidens*. Not only did we find the imperfect jaw of a young male with three upper teeth, but also some months later the snout of what appeared to be a female. The upper incisors and canine are typically human. Last month, while I was in America, my assistant, Mr. John T. Robinson, discovered an almost complete huge jaw with most of the teeth. I have, of course, not yet seen the specimen, but the accompanying drawings were made from photographs taken by Mr. Robinson. The jaw is really enormous—very considerably larger than that of Heidelberg man. The molar teeth are very large, but the canines and incisors remarkably small. Another remarkable feature about the jaw is that it has a rudiment of a chin. The ascending ramus is very high and large. Mr. Robinson has also got a part of the face with the nearly complete palate. This shows that the face is almost orthognathous. We must, I think, conclude that the brain was very large. It seems improbable that the brain can have been less than 800 c.c., and very likely it may have been more than 900 c.c. Mr. Robinson has just written me that he has part of a mandible with one molar tooth that looks remarkably human. While I can express no definite opinion until I see the specimen, it may be that the jaw is that of a small female of the same species as the large jaw."



Paranthropus crassidens Broom. Side-view and occlused view of left mandible. ½ natural size

British Gelatine and Glue Research Association

Mr. A. G. Ward has been appointed director of the newly formed British Gelatine and Glue Research Association. Mr. Ward's main interests have been in colloid science; in particular, the relation of colloidal structure to mechanical properties. During the War he was engaged on research on the mechanical and physical properties of propellants and plastics, together with studies on nitrocellulose, for the Ministry of Supply. This work included the use of X-ray diffraction technique to follow the changes in nitrocellulose structure in cordite manufacture. In 1946 he joined the Building Research Station of the Department of Scientific and Industrial Research to set up a Rheology Section for building materials, and he has since then published several papers on the rheology of pastes as well as two books on crystals and colloids.

Although the gelatine and glue industry is relatively small, its products are essential in many industries connected with food, photography, pharmacy and many household articles, and its by-products are fertilizers and fats. The industry has been founded on cheap raw materials such as hide waste and bones, and little change has taken place in traditional methods. Of late, production has expanded to meet all home needs and to capture export markets; but increased technical efficiency and new ideas are greatly needed if this activity is to be maintained. It was decided, therefore, in 1947 to form a Research Association. Preliminary work was done by the Federation of Gelatine and Glue Manufacturers, and already more than half the member firms have joined. The Research Association will work along the normal co-operative lines and will be assisted by a grant from the Department of Scientific and Industrial Research. Since the industry is not centred on any particular locality of Great Britain, the research laboratories will be set up in London. Work will be done in two main fields: fundamental research on raw materials and problems affecting the industry; and research with immediate practical application, including the possibility of new uses.

Italian National Awards: Einaudi Prizes

Through the generosity of Signor Luigi Einaudi, President of the Italian Republic, the Lincei Academy at Rome is to award four national prizes of a million lire each, at the end of every year of his term of office. The names of the first prize-winners have just been announced, as follows: General Prize (Mathematical and Natural Sciences): Prof. O. M. Olivo, of the University of Bologna, for researches in bio-electric phenomena of the cardiac cell; Prize for Physics: Prof. G. P. S. Occhialini, of the University of Brussels, for researches in nuclear physics and in particular for his work on the discovery of the heavy meson; General Prize (Moral Sciences): Prof. R. Mondolfo, of Bologna, for work on the history of philosophy; Prize for Archæology: Prof. C. Anti, of the University of Padua, for researches on ancient Greek theatres.

Science Service, Washington

At the recent annual general meeting of Science Service, Dr. L. A. Maynard, professor of nutrition and biochemistry of Cornell University, and Dr. Rene J. Dubos, bacteriologist and member of the Rockefeller Institute for Medical Research, New York City, were elected new trustees, being nominated by the National Academy of Sciences and the National Research Council, respectively. At the same time, the following officers were re-elected: *President*, Dr. Harlow Shapley, director of Harvard College Observatory; *Vice-President and Chairman of the Executive Committee*, Dr. Alexander Wetmore, secretary of the Smithsonian Institution; *Treasurer*, O. W. Riegel, director of Lee School of Journalism, Washington and Lee University; *Secretary*, Watson Davis, director of Science Service. Additional members elected to the Executive Committee were Frank R. Ford, editor, Evansville Press, Evansville, Ind., and Dr. Karl Lark-Horovitz, Purdue University. Science Service is an endowed, non-profit-making institution for the popularization of science. The board of trustees consists of three representatives each from the American Association for the Advancement of Science, the National Academy of Sciences, the National Research Council, the journalistic profession, and the Scripps Estate. The address of Science Service is 1719 N St., N.W., Washington 6, D.C.

An Unusual Solar Halo

MR. J. E. BOWMAN, Armament Research Establishment, Fort Halstead, Kent, writes: "On May 10 at Shoeburyness I observed a solar halo of an unusual size. For about the last hour before sunset a well-defined parhelion of the 22° halo was visible to the north of the sun; but there was no trace of the 22° halo itself. Just after the sun had set, however, the upper part of the 22° halo appeared, accompanied by a much smaller halo, the radius of which I estimated to be about 8–9°, and a sun pillar extending to some 15° above the sun. A patch of relatively greater brightness appeared where the sun pillar intersected the 8° halo. The whole spectacle, which lasted until a quarter of an hour after sunset, was extremely faint and could be distinguished only with difficulty. The display of halo phenomena continued after dark, for at 10 p.m. the moon was accompanied by the two paraselenæ of the 22° halo. Again, however, there was no trace of the 22° halo itself."

Co-operation between Universities and Technical Colleges

IN his address to a recent meeting of the Yorkshire Council for Further Education, Sir Ronald Weeks, chairman of the National Advisory Council for Education in Industry and Commerce, discussed the need for much closer co-operation between universities and technical colleges (*Tech. J.*, 41, No. 4; April 1949). Considering the place of the graduate in industry, Sir Ronald said that more attention should be given to the possibility of strengthening the science graduate on the technological side, and the Higher National Certificate student on the science side. Arrangements should also be made whereby graduate students could attend special courses of technology at the technical college either by block release or part-time study. Sir Ronald Weeks suggested certain principles for the provision of arrangements of this kind which must be observed. Among these are the following: both universities and technical colleges must be considered available for meeting the needs, having regard to their present facilities or possible future facilities; the convenience and needs of the students must come first, particularly in the case of part-time students; technical colleges must not be regarded as the poor relations of the universities, as this is fatal to co-operation and good understanding; there must be an easy means of transfer of students from universities to technical colleges, and vice versa.

Earthquakes during March

AT least eleven strong earthquakes occurred in the world during March. The greatest, and also the deepest, happened on March 4 from a focus having an epicentre near lat. 36·5° N., long. 70·5° E., in the Hindu Kush, Afghanistan. The depth of focus was probably rather greater than 200 km. and the strength 7½ on the instrumental scale. Owing to its strength and depth, the shock was felt over a wide area in Afghanistan and the North-West Frontier Province, Pakistan, and although the full extent of the damage is not yet assessed, the earthquake is known to have damaged the Roman Catholic cathedral in Lahore. The next most intense (scale *c.* 7) was probably that occurring on March 27 from a focus having an epicentre in the Celebes Sea off the southern coast of Cape Mindanoa. Strong shocks on March 16 and 17 had their epicentres in the region of the Bismarck Archipelago. On March 9 an earthquake with strength 5½ and epicentre near lat. 37·1° S., long. 121·3° W., in central California set off burglar alarms and rolled stones off Telegraph Hill, San Francisco, but did no serious damage. At Hollister some windows and plaster were cracked, and small objects were shaken off shelves. Of the small shocks during the month, three may be mentioned. On March 7 an earthquake was felt with strength 3–4 on the Modified Mercalli scale in the south-west Alps near Messtetten. It had a depth of focus, according to Dr. W. Hiller, of Stuttgart, of less than 5 km. On March 11 a strong tremor shook the area around Dalton, New South Wales, Australia, and cracked buildings there, causing damage estimated at £2,000. The shock was felt in Sydney and Canberra. On March 22 an earthquake was felt in the Département des Basses-Alpes, France, doing some damage at Lauzet. Instrumental readings for the month have been received from the central stations of the United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association; the Central Seismological Bureau at Strasbourg; and individual observatories at De Bilt (Netherlands), Durham, Stuttgart and Toledo.

Tellus: A New Journal of Geophysics

THE Second World War has brought losses and also gains in the periodical literature of geophysics. Among the gains is *Tellus*, a quarterly journal of geophysics issued by the Swedish Geophysical Society. Vol. 1, No. 1, February 1949, consists of 64 pages, and is obtainable from the Department of Meteorology, University of Stockholm, price 2 U.S. dollars. The Society was founded in 1920 to promote research and international collaboration in geophysics; but the institution of a regular journal is a new departure made possible by a Government grant and by the co-operation of the Lithographic Institution of the General Staff. Contributions, to be printed in English, French or German, are invited on all branches of geophysics, from all countries. The first issue, however, is practically an all-Swedish one, the authors concerned being Pettersson, Rydbeck and Stranz, Palmén, Bergeron, Nyberg, Rossby, Ahlmann, and Ångström. Five of the contributions are meteorological; one is ionospheric, being on the effects of solar flares; and two relate to marine expeditions, one prospective and the other that of the *Albatross*, to obtain sediment cores to study the geochronology of the deep ocean bed.

Institution of Mining and Metallurgy

The second Sir Julius Wernher Memorial Lecture of the Institution of Mining and Metallurgy will be given by Dr. C. H. Desch, who will speak on "The Effect of Impurities on the Properties of Metals". The Lecture will be delivered at the Royal Institution, 21 Albemarle Street, London, W.1, on July 6, at 5 p.m., and admission is free and without ticket.

The Institution will be holding a symposium on "The Refining of Non-Ferrous Metals" during July 7–8 at the Royal Institution of Chartered Surveyors, 14 Great George Street, Westminster, London, S.W.1. Tickets of admission (which are free) and further information may be obtained from the Secretary, Institution of Mining and Metallurgy, Salisbury House, Finsbury Circus, London, E.C.2.

Canadian Scholarship Awards

Scholarships have been granted by the National Research Council of Canada to 165 graduates to enable them to pursue postgraduate studies during the academic year 1949–50. There are nineteen fellowships at 900 dollars, sixty-four studentships at 750 dollars and seventy-eight bursaries at 450 dollars tenable at Canadian universities, and four special scholarships at 750 dollars awarded for study outside Canada. The nominal value of all scholarships for the year is 103,200 dollars as compared with the total for last year of 148 scholarships worth 97,050 dollars. Physics is represented by 65, and chemistry, in its several branches, by 59. The remainder are distributed in the other sciences as follows: bacteriology, 1; biology, 4; communications engineering, 1; cytogenetics, 1; electrical engineering, 2; geology, 3; histology, 2; mathematics, 3; medical research, 2; microwave studies, 1; metallurgy, 2; mineralogy, 2; nutrition, 1; physical metallurgy, 2; physiology, 1; radiation studies, 2; spectroscopy, 3; zoology, 8.

Colonial Service: Recent Appointments

The following appointments in the Colonial Service have been announced: G. Swaine, entomologist, Tanganyika; R. L. Woolridge, veterinary officer, Kenya; E. Pawson, agricultural chemist, Northern Rhodesia; K. L. Richards, livestock officer, Agricultural Department, Cyprus; A. J. Whitaker, electrical engineer, Nigeria; J. L. King (deputy electrical engineer-in-chief, Nigeria), electrical engineer-in-chief, Nigeria; J. M. Stock (senior electrical engineer, Nigeria), deputy electrical engineer-in-chief, Nigeria; J. R. Lockie (conservator of forests, Nigeria), assistant chief conservator of forests, Nigeria; R. Smeathers (assistant conservator of forests, Trinidad), deputy conservator of forests, Trinidad; J. H. Bowen (senior inspector of plants and produce, Gold Coast), chief inspector of plants and produce, Gold Coast; A. H. Fetherstonhaugh (control officer, Game Department, Federation of Malaya), chief game warden, Federation of Malaya; T. P. Lecky (agricultural officer, grade 2, Jamaica), senior livestock officer, Jamaica; W. G. Stuart (agricultural officer, grade 2, Jamaica), agricultural officer, grade 1, Jamaica; C. Teesdale (entomological field officer, Kenya), entomologist, Kenya.

Telecommunications at the Imperial College

Standard Telephones and Cables, Ltd., have endowed a readership, to be known as the Henry Mark Pease readership in telecommunications, in the City and Guilds College of the Imperial College of Science and Technology, London. Henry Mark Pease, one of the pioneers of the telephone industry in Britain, who died in March 1947, was managing director of Standard Telephones and Cables, Ltd., until 1928; he took an active part in forming the British Broadcasting Company, of which he was one of the original directors. Mr. E. C. Cherry has been appointed to the new readership. Mr. Cherry was attached to the Telecommunication Research Establishment of the Ministry of Aircraft Production during the war period and is known particularly for his contributions to the subject of electric circuit analysis.

The British Society for International Understanding

Sir Arthur Hall has been elected chairman of the British Society for International Understanding in succession to Mr. G. M. Young, the historian and literary critic, who has retired after holding the chairmanship since the Society's incorporation ten years ago. Sir Arthur Hall is director of studies at the Royal Naval College, Greenwich, and is also chairman of the English Association. Mr. Young remains chairman of the Editorial Committee of the Society's publication, *The British Survey*. Mr. Oliver Bell has been succeeded as vice-chairman of the Society by Colonel John Grace, of British Columbia, formerly director of education of the Canadian Army in Britain during the War.

Linnean Society of London: Officers for 1949

The following have been elected officers of the Linnean Society of London for the session 1949–50: *President*, Prof. F. E. Fritsch; *Treasurer*, Colonel F. C. Stern; *Secretaries*, Dr. B. Barnes (botany) and Dr. A. Tindell Hopwood (zoology); *New Members of Council*, Prof. A. J. E. Cave, Dr. E. B. Ford, C. C. Hentschel and Dr. C. F. A. Pantin.

Announcements

Mr. Geoffrey Munday, of the South-West Essex Technical College, who has been carrying out research on the temperature variation of the optical properties of gold, has been appointed a research-associate at the Massachusetts Institute of Technology.

A Summer School in X-Ray Analysis, somewhat similar to those held in Manchester and Cambridge in previous years, is to be held in Leeds during the period August 29–September 10. Further information can be obtained from Prof. E. G. Cox, Department of Inorganic and Physical Chemistry, University, Leeds 2.

The French Association for the Advancement of Sciences will hold its sixty-eighth annual congress at Clermont-Ferrand, during July 15–21.

Erratum. In a footnote to the communication entitled "Inelastic Scattering of Protons by Magnesium and Aluminium" in *Nature* of May 28, p. 848, the present address of the author, E. H. Rhoderick, is wrongly stated; it should be Department of Natural Philosophy, University of Glasgow.

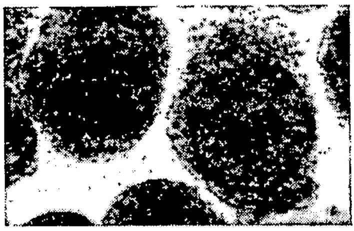
Absorption of Ultra-violet Light by Living Cells

NUCLEIC acids, because of the presence of purines and pyrimidines in the molecule, absorb ultra-violet light with a maximum absorption at 2600 A. Recently, Larionow and Brumberg[1] suggested, on the basis of ultra-violet light photomicrographic studies, that desoxyribonucleic acid, as it exists in the nuclei of living cells, does not absorb ultra-violet light of wave-lengths near 2600 A. These investigators contended that absorption develops as a result of injury or death of the cell.

Ultra-violet light photomicrographs of living cells made in this laboratory show absorption of light of wave-length 2654 A. Cells of the Walker Carcinoma No. 256 of the rat were used. Cell suspensions were prepared immediately after removal of tumours from the host by mincing tissue finely with scissors in Ringer's solution and straining through a thin layer of cotton to remove coarse aggregates. Cells prepared in this manner and kept for much longer periods of time than was required in these experiments produced tumours when implanted into rats. The cells, in Ringer's solution, were placed on a quartz slide and covered with a quartz coverglass and sealed with paraffin.

Ultra-violet light photomicrographs were made with a quartz optical system microscope by the method previously described[2], with a 2·5-mm. objective, N.A. 0·85 and a 10 × ocular, magnification 240 ×. Condenser diaphragms were closed to small aperture.



Ultra-violet light (2654 A.) photomicrograph of Walker Carcinoma No. 256 of the rat, magnification × 900

Focusing was performed by means of a fluorescent screen and a magnifier with 2654 A. light. The focus was obtained on one area of the field; all light was then barred from the microscope, and the slide was moved to a distant field. In this procedure the cells were exposed to only the amount of ultra-violet light necessary to produce the image on the film. Panatomic X (Eastman Kodak Co.) was used. Photomicrographs made in this manner (see illustration) show the same absorption pattern as those made after the cells have been exposed to several times the amount of ultra-violet light necessary for photomicrographs.

Nuclear and cytoplasmic absorption varied considerably from cell to cell, depending on the metabolic state. Chromosomes, where present, absorbed intensely. In the resting cells the nucleolus usually absorbed much more intensely than did the remainder of the nucleus.

Visual observations of fluorescent images of cel illuminated by ultra-violet light made by rapidl moving the slide across the microscopic field reveal absorption by cells as they came into view; unde these conditions exposure to ultra-violet light wa less than one second. Chicken erythrocytes in whol blood when observed in this manner within three t five minutes after drawing the blood showed intens nuclear absorption. These observations, which hav been repeated many times, indicate that the nuclei acids as they exist in the living cells absorb ultra violet light. This contention is supported by th work of Wyckoff[3], who made successive ultra-viole (2750 A.) photographs of a living grasshopper sperm atocyte and showed absorption by the chromosome throughout division.

Plant Injury from Phosphorus-32

IT has been generally considered, on the basis o the work reported by Hendricks and Dean[1], that sufficient margin of safety exists in the tolerance o the plant to radioactivity to permit the use o phosphorus-32 as a tracer in phosphate experiment without fear of any effects on plant growth from th radioactive isotope. The recent communication b Scott Russell and Martin[2], indicating an injuriou effect, suggests that a danger exists which require further study.

In the course of field experiments with wheat i Saskatchewan in 1948, phosphorus-32 was used t follow the uptake of phosphate from seven differen fertilizer treatments. Only one row (9 ft. long) i each treatment plot was treated with radioactiv fertilizer; but the two immediately adjacent row were treated with exactly the same amount of th same inactive fertilizer. While this was done t avoid handling large amounts of tracer, and also t check the amount of fertilizer applied with the seed in one row taken up by adjacent rows, the arrangement was ideal for an estimation of effects due t phosphorus-32.

Fertilizer was applied to give P_2O_5 applications of 12, 24 and 48 lb. of P_2O_5 per acre. Two dilutions of phosphorus-32 were used, one at 26 microcuries and the other at 260 microcuries per gram of phosphorus (both measured at time of planting), in connexion with harvests at four different stages of growth. We therefore have information on identical fertilizer treatments, with and without phosphorus-32, at various stages of growth, and at two levels of phosphorus-32 activity. The application of P_2O_5 at 48 lb./acre is the treatment most likely to show injury, since the absolute uptake of phosphorus-32 was highest for this treatment.

Measurements of yield, total phosphorus and phosphorus-32 were made as in previous work[3]. The data are presented below.

Some of the data indicate a small but statistically significant increase as a result of the presence of phosphorus-32. This requires a word of explanation.

(*a*) Plants harvested at 2–3 weeks; P^{32} applied at 26 μc./gm. P^{31} at time of planting

Phosphate treatment	lb. P_2O_5 per acre	Location *B*			Location *H*		
		% of applied P taken up	Plant wt. (gm./6 ft. row) Active rows	Inactive rows	% of applied P taken up	Plant wt. (gm./6 ft. row) Active rows	Inactive rows

L.S.D. 5% pt.			0·8			1·9	

Mean of all treatments, first harvest: active rows, 11·8; inactive rows, 10·4; L.S.D. 5% pt., 1·0
A, $NH_4H_2PO_4$; *B*, NaH_2PO_4; *C*, $CaH_4(PO_4)_2$; *D*, $Ca_2H_2(PO_4)_2$; *E*, $Ca_2H_2(PO_4)_2 + Ca(NO_3)_2$

(*b*) Plants harvested at various stages: treatment *A*, 48 lb. P_2O_5/acre

Stage	Age in weeks	Activity at planting (μc./gm. P^{31})	Location *B*			Location *H*		
			% of applied P taken up	Plant wt. (gm./6 ft. row) Active rows	Inactive rows	% of applied P taken up	Plant wt. (gm./6 ft. row) Active rows	Inactive rows
Shot blade	2–3	26	3·1*	12·3*	11·0	3·0	13·7	8·2
Heading	5½	26	17·9	69·4	72·5	12·3	72·1	71·2
Soft dough	7½	26	21·1	143·4	139·5	12·4	97·4	86·3
Maturity	11½–12	260	25·0	189·9	189·2	13·6	123·2	124·6
Mean				103·7	103·0		76·6	72·6
L.S.D. 5% pt.				12·0			8·8	

Mean of both locations, all dates: active rows, 90·2; inactive rows, 87·8; L.S.D. 5% pt., 9·6
* These figures are means of four plots. Statistical analysis was by Student's Pairing Method, using the individual figures, rather than means

A little bias at the first harvest at Location *H* resulted from uneven germination. In the original 9-ft. row, 3 ft. were chosen for harvest, taking 6 ft. also from the non-active rows alongside. The active row, which was of greatest interest, was taken to give the most uniform continuous 6 ft. of growth, but occasionally this meant that gaps occurred in the adjacent rows for that particular plot. We do not consider that any real benefit results from the use of phosphorus-32.

The results indicate no signs of harmful effects from phosphorus-32 as used in this experiment. This would confirm Hendricks's and Dean's original conclusion that there is sufficient tolerance to make the avoidance of injury from phosphorus-32 a relatively easy matter, at least for field experiments.

Cold Hardiness and Seed Shape in Maize

At least one mid-Western seed company has asserted that 'round-grade' dent corn (maize) seeds withstand more than 'flat-grade' seeds the cold weather after early spring sowings.

Fifty seeds of both kinds of six single-cross and one double-cross hybrids were used to test this. These were kindly supplied by Mr. H. Everett. Seeds were placed in seed-boxes containing soil and lightly covered with it. Two rows of round seed were followed by two rows of the corresponding flat seeds of each hybrid, approximately twenty-five seeds per row. Treatment was by the method of Haskell[1]. The seed-boxes were placed in a 50° F. room and watered when necessary. After eight days they were removed to a warm greenhouse. Maximum germinations were recorded.

Behaviour of round and flat dent corn seed subjected to 50° F. for 8 days

Pedigree	Round			Flat		
	Av. wt. of 10 seeds	% germ.	Angular germ.	Av. wt. of 10 seeds	% germ.	Angular germ.
	(gm.)			(gm.)		
267 × 263·5	4·37	92	73·6	3·58	98	81·9
274 × 263·5	4·68	86	68·0	3·83	88	69·7
251 × 450·6	3·74	100	90·0	3·12	90	71·6
277 × 275	3·73	64	53·1	3·05	80	63·4
268 × 263·5	4·03	84	66·4	3·59	78	62·0
284 × 283	3·92	44	41·6	3·37	50	45·0
Conn 520	—	8	16·4	—	28	31·9
		Mean	58·4		Mean	60·8

The accompanying table gives the values in percentages and angles; the average weight of ten seeds of each type is also given. Germinations of round and flat seeds are very similar, even though round ones are somewhat heavier than flat seeds. An analysis of variance was made on the angular values. χ^2 values were obtained by dividing the sum of squares by the theoretical variance, given by 820·7/50. Each χ^2 had a significantly low probability, especially that for error, or variation within the series. Therefore, using the error mean square, values of *t* were also obtained.

For flat and round seeds, $t_{[6]} = 0·55$, which is not significant. Variation between strains gives *V.R.* = 12·9, which has a probability *P* of < 0·01, suggesting differential behaviour between the hybrids. However, in view of the high value of χ^2 for the error item, it would seem that there is an indirect effect due to the round/flat condition which may be due to some linked quality associated with this difference, rather than to an immediate effect.

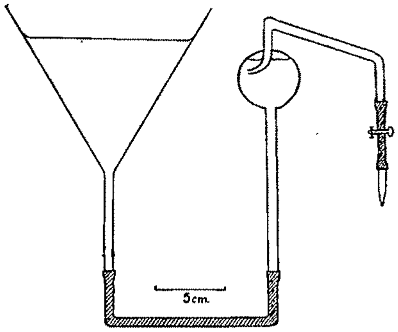
Continuous Sedimentation for the Concentration of Trematode Eggs in Fæcal Suspensions

METHODS of concentration for helminth eggs, such as centrifuging with sodium chloride or zinc sulphate solutions and looping off the surface, or the Gordon – Whitlock egg-counting technique for nematode eggs in sheep fæces, cannot successfully be used for trematode eggs because these collapse in hypertonic solutions owing to their thin shells. The use of chemicals and even the mere act of centrifuging may damage the eggs and render subsequent culture unsuccessful. Multiple sedimentation of fæcal suspensions is laborious and time-consuming. The apparatus shown in the sketch will wash away the colouring matter and reduce the fæcal debris to less than half with the loss of only very few eggs. The resulting suspension is of a consistency which will greatly facilitate other operations, such as dilution egg-counts and straining through bolting silk.



This apparatus has been used successfully with sheep fæces for the concentration of trematode eggs. The apparatus is filled with water, except for the air lock in the bowl of the 'distillation splash head', and a suspension of the fæces in water, after having been passed through a 40-mesh per inch sieve, is placed in the funnel. The spring clip is released and the fæcal suspension siphons over; the heavier particles and eggs settle in the bowl. When the operation is almost completed, the funnel is washed round with a few c.c. of water. Recovery of the eggs is easily effected by disconnecting the tubing from the funnel and running the suspension, after agitation, from the splash head into a vessel.

With 6 gm. of fæces in 200 c.c. water and using a splash head with bowl of 4·5-mm. diameter, an escape jet which passes 30 c.c. of water in 1 min. was found to be the most successful. The rate of flow can be adjusted by using different escape jets, and may conveniently be graded according to the number of c.c. which pass per minute.

Examples of egg recovery using 6 gm. of fæces from sheep infected with trematodes

Trematode	No. of c.c. per min. passed by jet	Eggs recovered	Eggs lost
Fosciola hepatica	30	541	6
		252	16
		85	7
		723	11
		647	30
	40	229	16
Paramphistomum cervi	30	66	Nil
		87	Nil
	40	106	4

This apparatus may possibly be of use for other suspensions of eggs in water. It has not proved satisfactory, however, for strongyle eggs; the specific gravity in this case is too near that of water.

Effect of Young Grass in the Diet on the Onset of Sexual Maturity in Mice

THE superior nutritive qualities of spring grass as compared with the autumn growth or aftermath, etc., have been attributed to a better and more varied supply of basic nutrients (for example, amino-acids) in the former[1]. While there is undoubtedly some truth in this, it has been slowly realized that the phenomenon may be more complex, and that there are factors in young grass which influence the endocrine system in such a way as to have a direct bearing on productivity (growth, meat and milk) as well as on reproduction (œstrous cycle)[2].

We wish to report some preliminary work (spring, 1947) on laboratory animals which may have a bearing on these problems. Young female mice were placed, immediately after weaning, in three groups on the following diets: (1) Basal diet (B.D.H. light white casein 20 parts, sucrose 60 parts, arachis oil 15 parts, B.D.H. salt mixture 3 parts and dried yeast 10 parts). (2) Basal diet with a supplement (*ad lib.*) of fresh grass cuttings. (3) Basal diet supplemented with dried grass.

All the animals were dosed with tocopherol and radiostoleum. There were twelve mice in each group, and their growth curves and the onset of maturity, as indicated by the opening of the vagina, were noted.

Group	Mean age (days) at vaginal opening	Average weight (gm.) at start of experiment	Average weight (gm.) 45 days old
1. Basal	51 ± 3·7	9·1	19·9
2. Basal and fresh grass	41 ± 4·0	10·1	20·5
3. Basal and dried grass	43 ± 5·0	9·4	19·7

The growth curves in the three groups did not differ appreciably; but the onset of sexual maturity was markedly hastened in the mice receiving a supplement of grass in their diet.

Folley *et al.*[3] have given evidence of the presence of œstrogenic substances in grass by the injection of certain extracts into immature mice. It seems from our preliminary work that laboratory animals such as mice, by natural feeding on a diet in which young grass has been included, do respond as if they were getting a continual small supply of 'œstrogenic substances' from the diet. Bennetts *et al.*[4] demonstrated that sheep grazing a pasture of subterranean clover could ingest sufficient substance of this type to bring about symptoms of œstrogen hyperactivity. The work of Phillips *et al.*[5] directs attention to the effect of climatic conditions on the distribution of both the rate of calvings and of lamb-weights in West Wales. It seems that climatic conditions affect farm animals both directly, and indirectly, through the pasture. Apart from the general basic nutritive differences, it is possible to predict that factors such as the above should be taken into account in assessing these problems.

The Tricarboxylic Acid Cycle in Nematode Parasites

In nematode parasites the anaerobic breakdown of glycogen to pyruvate and lactate with a consequent formation of adenosine triphosphate follows a course similar to that in vertebrate muscle[1]. Since it appears that aerobic mechanisms may play an important part in the metabolism of certain nematode parasites[2], studies on the carbohydrate metabolism of the parasites have been extended to include some aspects of the oxidative utilization of pyruvate. The organisms used were *Ascaridia galli* from the chicken small intestine and *Nematodirus spathiger* and *N. filicollis* from the sheep small intestine. Some experiments were also carried out with *Neoaplectana glaseri*, a parasite of the Japanese beetle, which, however, was grown *in vitro* for the present experiments. Owing to its relatively large size and its position in the host, *A. galli* may not have an active aerobic metabolism *in vivo*. However, it has been shown that *Nematodirus* spp. probably respire actively *in vivo*, and oxygen is essential for the survival *in vitro* of *Neoaplectana glaseri*.

Experiments were carried out using brei prepared from whole parasites suspended in Krebs – Ringer phosphate buffer at *p*H 7·3. The results were not appreciably affected by omitting calcium from the medium. Oxygen consumption at 38° C., determined by the 'direct' method of Warburg, varied somewhat with different lots of parasites, but Q_{O_2} values (µl. of oxygen taken up per hour per mgm. dry weight, taken over the first period of 30 min.) were usually in the region of 3·8 (*Nematodirus* spp.), 4·0 (*Neoaplectana glaseri*), or 4·2 (*A. galli*). Cytochrome *c* or methylene blue increased oxygen uptake, and, as a routine measure, experiments were carried out with the brei in $M/3,000$ methylene blue.

Co-factors such as co-carboxylase, coenzymes I and II, pantothenate, riboflavin, nicotinic acid and pyridoxine did not markedly affect the oxygen uptake. However, in increasing order of activity the substrates pyruvate, malate, α-ketoglutarate, fumarate and succinate, at concentrations of $M/100$, all caused increased oxygen uptake. Oxalacetate ($M/1,000$) caused a stimulation of the same order as pyruvate. Citrate ($M/100$) had little effect. These results suggest that some form of Krebs tricarboxylic acid cycle was functioning in the parasite tissues. However, compared to pigeon breast muscle, the parasite tissue was relatively insensitive to malonate. Further, results taken over the first 30 min. of an experiment always showed that malonate inhibition was *increased* in the presence of added succinate. When the period of observation was confined to the first 10 min. of the experiment, the effect of succinate on malonate inhibition was less marked; but as a rule, as shown in the accompanying table, inhibition was *increased*. Pyruvate, fumarate and malate, at concentrations of $M/100$, all markedly reduced the inhibition caused by $M/50$ malonate. One interpretation of these results would be that, though a form of the Krebs tricarboxylic acid cycle is functional in the parasite tissues, succinate oxidation, relative to the total oxidative activity, is less important than in pigeon breast muscle.

Effect of malonate and succinate on the oxygen consumption of brei from pigeon breast muscle and nematode parasites. The figures give the percentage inhibition found during the first period of 10 min.

Conditions	Pigeon breast muscle	*Nematodirus* spp.	*Ascaridia galli*	*Neoaplectana glaseri*
Malonate, $M/100$	50–70	25	11	8
Malonate, $M/100$ } succinate, $M/100$	—	40	43	16
Malonate, $M/1000$	30	0–10	0–10	0
Malonate, $M/1000$ } succinate, $M/1000$	5			

The difference in the reaction of the parasite tissues and pigeon breast muscle to malonate was also examined by determining the accumulation of succinate, by the method of Krebs[3], in brei from the different organisms which had been incubated for 1 hr. at 38° C. In the absence of malonate, no succinate was found in the parasite preparations and very little in the breast muscle. However, in $M/100$ malonate, succinate accumulated in the muscle brei but still was not found in the parasite material. Even when $M/100$ malonate and $M/100$ fumarate were added to the parasite brei, succinate accumulation did not occur or was very small indeed.

A detailed account of this work, which was part of the research programme of the Division of Animal Health and Production, Council for Scientific and Industrial Research, will be published elsewhere. A note on the nature of substrates, other than those of the Krebs tricarboxylic acid cycle and the mechanism by which they are metabolized by the parasites, will be published shortly.

Yellowing Disease of 'Family 41' Sugar Beet

In a preliminary note[1], Clinch, Loughnane and McKay describe a yellowing disease in a breeder's 'pure line' of sugar beet (family 41), which is transmissible through the seed and also by the aphis, *Myzus persicæ*. Recently, Clinch and Loughnane have published a paper[2] on this disease with the title "Seed Transmission of Virus Yellows of Sugar Beet and the Existence of Strains of this Virus in Eire". This title is, in our opinion, misleading, for it suggests that sugar beet yellows virus is transmitted by seed. There is, on the contrary, much evidence that it is not, and though the yellowing of family 41 may be transmitted through the seed, there is nothing to show that the condition is caused by beet yellows virus.

Clinch and Loughnane's conclusion that the yellowing disease of family 41 is beet yellows virus is based solely on symptomatology, particularly on the accumulation of carbohydrates in the yellowed areas of the leaves. However, this is by no means specific to beet yellows virus, nor to virus diseases, for leaves yellowed by downy mildew (*Peronospora schachtii*) are abnormally high in carbohydrate.

In family 41 the symptoms somewhat resemble those of sugar beet yellows; but in field conditions many plants, particularly those which do not inherit the disease, but become infected later, show important distinguishing features. The chlorotic areas are pale; the outlines finely indented with sharply defined lobes and scattered chlorotic spots. With sugar beet yellows the yellowing is brighter, and the outlines of the chlorotic areas are not sharply defined unless bounded by veins. When the disease from family 41 is introduced into other varieties of sugar beet, the symptoms are very weak and ephemeral. Often only one leaf per plant shows any definite yellowing or thickening, and when this leaf dies the plant may be indistinguishable from a healthy one.

Clinch and Loughnane state that the cause of the yellowing in family 41 is transmitted by *M. persicæ* to other sugar beet varieties as readily as mild strains of beet yellows virus. We have not been able to confirm this. Using 10–20 aphides per plant and long feeding times (at least 48 hours on infected and healthy plants) we have never been able to obtain more than 10 per cent of infection in commercial varieties, and often there appears to be no transmission at all. Kleinwanzleben 'E' plants grafted with yellowed plants of family 41 remained apparently healthy. The mild strains of beet yellows virus which we have used[3] are transmitted by comparatively small numbers of aphides after a few hours of feeding.

Sap from plants infected with our mild strains of beet yellows virus is precipitated by antiserum prepared against the severe strains, but saps from yellowed plants of family 41 are not.

Much evidence will be needed before the relationships, if any, between the cause of the yellowing in family 41 and sugar beet yellows virus are understood; but the fact that some seedlings of family 41 have a transmissible chlorosis does not in any way affect the control of sugar beet yellows. There is no reason to consider that beet yellows is transmitted in the seed of any commercial variety of sugar beet; nor is there yet any evidence that the cause of the yellowing in family 41 is transmitted by seed in any of these varieties. Indeed, there is no evidence that the cause of the yellowing in family 41 resulted, in the first place from seed transmission in the normal sense, because it is not known that the parent plants were infected with beet yellows or with any other virus. The phenomenon could be explained on the more interesting hypothesis that the yellowing shown by plants of family 41 has originated in that particular genotype. The sharp definition of the chlorotic pattern suggests an analogy with variegation arising from plastid mutation such as that of maize, described by Rhoades[4]. It suggests also that, if the cause is a virus, it moves with unusual difficulty from cell to cell. This hypothesis might explain the difficulty in infecting sugar beet varieties that regularly become systemically infected with sugar beet yellows.

Movement of Zooplankton in Diatom Gradients

Hardy and Gunther[1] and Harvey *et al.*[2] have proposed somewhat opposing hypotheses in explanation of a phenomenon widely observed in the sea, namely, an inverse correlation in catches of zooplankton and phytoplankton. Hardy's hypothesis, that of "animal exclusion", is supported in some degree by the experimental work of Lucas[3]; and Harvey's, of the "grazing effect of zooplankton", by various observations on rates of feeding, and statistically by Fleming[4] and others.

The apparatus illustrated in Fig. 1 was devised in order to determine experimentally the behaviour of zooplanktonts when presented, under certain

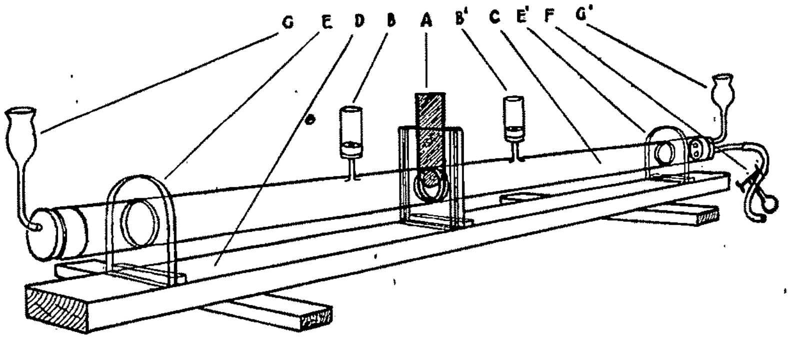

Fig. 1. Perspective view of apparatus. *A*, Sliding door (half open); *B B'*, entrance tubes for animals; *C*, glass tube; *D*, wooden base; *E E'*, 'Perspex' supports; *F*, draining tube with clip; *G G'*, filling funnels for diatom culture

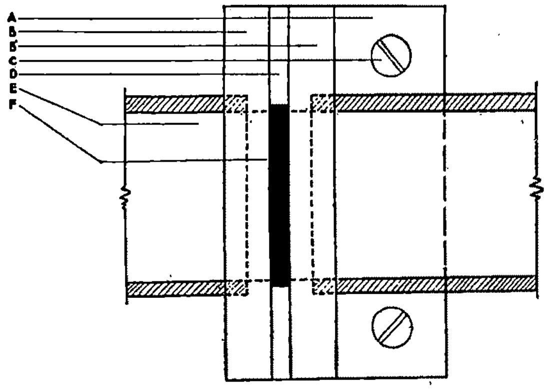

Fig. 2. Working plan of door component. *A*, 'Perspex' supporting bracket; *B B'*, 'Perspex' cheeks recessed for tube; *C*, securing screw; *D*, 'Perspex' spacing piece; *E*, terminal part of glass tube; *F*, sliding door

conditions, with a choice between concentrated diatom cultures and sea water. It consists of a cylindrical glass tube of *c*. 40 in. length and 1 in. diameter, divided in the centre by a removable transparent 'Perspex' sliding door and carrying tubes and funnels for the introduction of cultures and animals. Into one side of this apparatus were put cultures of *Nitschia closterium* (Plymouth strain) grown in sterilized sea water enriched with Allen and Nelson's[5] modification of Miquel solutions. Into the other was put enriched but otherwise pure sea water. Upon opening the sliding door, a visible gradient of diatoms was set up, usually in about the central third of the apparatus, although its length varied with the conditions of the experiment. Zooplanktonts were then introduced in equal numbers into each side and their distribution recorded at intervals for from 1½ hr. variously up to two days. The gradients cannot be observed after about thirty-six hours as movement of the animals tends to destroy them.

Using *Neomysis vulgaris* taken from the River Humber, twenty-eight experiments were performed; eleven with diatoms adapted to growth in 50 per cent sea water and seventeen with 100 per cent sea-water cultures diluted to 50 per cent just before the experiment. No excluding effect of the diatoms could be demonstrated; but a vigorous and often total movement of animals into the diatom side of the apparatus occurred. This movement was most marked with starved individuals and least with fed ones. There was no movement into water immediately filtered from a growing diatom culture, nor was it invoked with water coloured to simulate diatom culture (using pigments shown independently not to be inimical to these mysids), and it did not occur in the dark. There was movement into freshly taken river water (17·5 per thousand salinity) in which living diatoms filtered from a culture had just previously been suspended. Finally, diatoms from a culture were killed by heating to 80° C. for about twenty minutes, filtered off, washed three times on the filter and resuspended in river water. Undiminished movement into this suspension occurred. The number of animals used in each experiment was sixteen, and the diatom cultures were of a concentration of about 1,000 cells per c.mm.

Restricted experiments with *Eurytemora hirundoides* and *Macropsis slabberi* gave similar results, and the movement has also been demonstrated, less effectively, in a vertical apparatus.

The movement of the animals under these conditions seems to be dependent upon the physical presence, in the light, of the diatoms on which they are feeding. These observations provide no evidence in support of Hardy's exclusion hypothesis. It is emphasized, however, that only estuarine animals have been used and that the natural distributions of these particular species have never been shown to be inversely correlated with the occurrence of phytoplankton. The rate of movement of individuals in the horizontal tube, however, was of such an order (*c*. 2 yards per minute) as to be of importance should it be sustained in a constant direction in the sea. It could, were the hypothesis of Harvey correct, be a contributory factor in the production of the grazing effect.

It is intended to apply the technique to an investigation into the relationships of other diatoms and open-sea animals, but this will not be possible for some months, for which reason this preliminary note is now submitted.

Keeping Lampreys Alive

It has come to my notice that others working on lampreys have had, like myself, difficulty in keeping them alive. Since I have been successful both this year and last in keeping the river lamprey or lampern (*Lampetra fluviatilis*, L.) alive over long periods, the following observations may be of interest.

The essential requirements would seem to be: (1) a liberal supply of oxygen, (2) a means of keeping the temperature of the water below 15° C., (3) absence of direct light.

If the water cannot be artificially aerated, a small number of lampreys (not more than twelve) can live quite well in still water 5 cm. deep providing there is a surface area of not less than 2 square metres. If the depth of water is increased, the lampreys very quickly die from lack of oxygen. Mains water running into a sink with a high overflow often kills lampreys within half an hour.

My stock tank in which I am keeping more than one hundred lampreys measures 7 ft. × 2½ ft. × 3½ ft., and it has 12 in. of water which is kept in constant circulation by a 24-V. D.C., ex-R.A.F. turbine (petrol) pump at one end of the tank, which delivers the water to the top of an aerating tower at the opposite end of the tank at the average rate of 2 litres per minute. The water falls over a series of louvres covered with chicken grit which offers a total surface area of approximately one square metre. The water takes 15 sec. to pass through the tower, the bottom of which is one foot above the level of the water in the tank below.

If the circulation is stopped for as little as one hour, the lampreys are seen to be in respiratory distress, breathing is rapid (more than 200 per minute) and shallow, the lampreys fall over on their sides and are unable to right themselves or to grip with their sucker. If the circulation is then restarted, the lampreys recover completely within two or three hours.

My tanks are of heavily galvanized iron and rest on a stone floor in a basement room which is kept cool by a through draught of air. Last winter the outside windows were closed in error one week-end. This caused the temperature of the water to rise from 13° C. to 22° C., and despite the fact that the water was still circulating all the lampreys had died.

The high sides of the tank cut out direct light and keep the lampreys from jumping out when they are being netted.

Details of the apparatus and experiments will be published elsewhere.

Note added in proof. The pump mentioned above has since been replaced by a $\frac{1}{3}$ h.p. A.C. centrifugal pump which needs little servicing.

Feeding-Rates of Sponges, Lamellibranchs and Ascidians

MANY water-living animals obtain their food from suspended material, micro-organisms or fine dispersed detritus occurring in the surrounding water. Sponges and ascidians, for example, are typical filtering animals. Most lamellibranchs belong to the same group. But filtering forms may also be found among gastropods, crustaceans, insects, polychætes, vertebrates, etc. Apart from lamellibranchs, little information is available regarding the rate and efficiency with which particles are retained from water passing the filtering organs. Bidder[1] calculated the water propulsion through *Leucandra aspersa* (a sponge), whereas investigations on the rate of feeding of ascidians seems to be lacking. During a stay at the Plymouth Laboratory, I was offered an opportunity of determining the feeding-rates of species of sponges and ascidians. The feeding-rates have been calculated from the rate of disappearance of particles from the surrounding water[2]. Suspensions of colloidal graphite were used, namely, 'Prodag' grade C and 'Aquadag' grade S, manufactured by E. G. Acheson, Ltd., London; the former has an average particle size of 4–5 μ, whereas the latter has an average particle-size of 2 μ. The concentrations of the graphite suspensions were determined photometrically by means of a portable Eel photometer.

The results of the experiments are given in the accompanying table. The feeding-rates are expressed as per mgm. of amino-nitrogen of the experimental animals instead of the normally used weight and length or similar measurement, which provide an unsatisfactory basis for comparisons between animals. In the table are also included results obtained on *Mytilus edulis*, which will be published in greater detail elsewhere[3]. It is seen that—when expressed in relation to the amino-nitrogen content, which may be regarded as a measure of the amount of protoplasm in the animals—the feeding-rates of the species investigated are all of the same order of magnitude, *Halichondria* and *Mytilus* showing somewhat lower values. However, the experiments on *Halichondria* were carried out on a fragment weighing about 50 gm., whereas the calcareous sponges used were all smaller intact specimens.

Species	Number of animals in each experiment	Length (cm.)	Average content of amino-nitrogen (mgm.)	Feeding-rate ml./hr., per mgm. amino-nitrogen
Ascidians				
Molgula sp.	20	1–2	1·8	138, 124, 285, 118, 149, 115
Ciona intestinalis (L.)	2	6–7	6	125, 92, 104
,, ,, ,,	3	6–7	5·3	125
Sponges				
Grantia compressa (Fabricius)	1	7	8·5	135
,, ,, ,,	9	3–7	3·3	180
Sycon coronatum (Ellis and Solander)	9	4–6	2	200, 145
Sycon + *Grantia*				170
Halichondria panicea (Pallas)				65
Lamellibranchs				
Mytilus edulis (L.)		*c.* 3	25	36
,, ,, ,,		*c.* 1·5	2	80

The feeding-rates of sponges and ascidians were found to be independent of the particle-size, which varied from about 2 μ and 4·5 μ respectively and upwards. The upper limit of the particle-size in the suspensions was not known, as the graphite did not form fully dispersed suspensions in sea water. A certain amount of aggregated particles was always observed when the suspensions were examined under the microscope.

As regards the ascidians, the independence of feeding-rate and particle-size is in good agreement with the view held by MacGinitie[4] concerning the feeding mechanism of ascidians. He observed that ascidians when feeding are covering the gill basket with a continuous layer of mucus which retains all particulate matter in the water transported through the gills.

My thanks are due to the director, Wing-Comdr. F. S. Russell, for placing the working facilities of the Plymouth Laboratory at my disposal, and for his great interest in my work. The investigations were made possible through a grant from the Rask–Ørsted Foundation.

Varagu Poisoning

Varagu (Tamil), *kodo*, *kodaka* (Hindustani), *Paspalum scrobiculatum* (Linn.), is a millet largely used by the working and poorer classes of people in all parts of India as a staple article of food. More than 300,000 tons of this millet is produced in the Madras Presidency alone. In 1946, when rice was rationed and millet eaters were compulsorily asked to take a portion of their requirements in rice and millets in the form of *varagu*, complaints were received that consumers in several parts of the Presidency developed symptoms of food poisoning as a result of eating *varagu* in the cooked as well as the raw state.

The symptoms observed within twenty minutes of taking the food were tremors, giddiness, perspiration, inability to speak or swallow. There were no fatalities, and the symptoms disappeared after twenty-four hours, though the persons affected had to be taken to hospital for treatment.

It was difficult to feed monkeys, as they refused to take the food. Two ounces of the millet produced the same symptoms on dogs; tremors and paralysis were characteristic effects, and the dogs died in twenty-four hours. The Stas Otto test was negative, showing the absence of alkaloids. The fat was extracted with petroleum ether (60–95° C.), or chloroform, or ether, and it was found that 1·5 gm. of fat corresponding to 50 gm. of the millet were fatal to dogs. The fat had the following figures (average):

Melting point	42° C.
Refractive index (60° C.) ..	1·4650
Iodine value	93·6
Saponification value	170·7

The defatted residue was found to be non-toxic. The poison in the fat seems to be decomposed by dilute acid and alkali, as after acid and alkali treatment the treated fat is no longer poisonous. The liquid, decanted after shaking the millet with petroleum ether, develops a characteristic red colour when shaken with concentrated sulphuric acid. But as the fat in the millet after treatment with dilute acid—when it is no longer poisonous—still gives the colour test, it is inferred that the colour observed is not due to the poison in the fat but to a decomposition product of it. The poison seems to be neither an alkaloid nor a glucoside, as it is not extracted with acid, water or 90 per cent alcohol. It seems to be adsorbed chromatographically in silica column. Further work is in progress.

The fat obtained from non-poisonous varieties of *varagu* is quite harmless, and does not give the sulphuric acid test described above.

The most surprising observation is that the fat derived from the poisonous variety develops symptoms of poisoning in dogs and monkeys when injected intramuscularly, 1 gm. of the fat being fatal. Crows seem to be extremely susceptible to the poison in the fat, either when ingested orally or injected intramuscularly. Within ten minutes of oral ingestion, the crow puts down its beak and vomits; even after all the contents have been vomited the crow puts down its beak in an effort to vomit. It loses the mobility of its eyes and soon its power of using its legs, while the wings are spread out and can no longer be brought together. The crow dies in twenty-four hours. The effects are slow when the fat is given by injection; but the collapse is more pronounced and the symptom of vomiting, even when there is nothing to vomit, is a characteristic of the poisoning in the crow.

These observations do not appear to have been recorded so far in the literature. They give a means of distinguishing the poisonous from the non-poisonous variety, and it should lead to the reclamation of an important article of food which, of late, has come into disrepute owing to the ill-effects attending its consumption.

Rh Phenotypes and Fisher's *CDE* Notation

Since the introduction of Fisher's theory and notation[1] of the *Rh* blood-group system, the tendency has been to express phenotypes in terms of the probable genotype. This method is most convenient for European populations, where every common phenotype consists very largely of a single genotype; but its extension to non-European populations usually involves serious ambiguities. In this and other connexions, there is an undoubted need for an unambiguous and generally understood phenotype notation expressed in Fisher's symbols, which would be available to supplement current practices. Several attempts have been made to express phenotypes with the use of these symbols, probably the earliest being that of Bushby[2]. The present proposals closely resemble those of Bushby; but allowance is here made for the fact that the six typing sera (anti-*C*, *D*, *E*, *c*, *d*, *e*) are not usually all available as Bushby tacitly assumes. No originality is claimed for these proposals; it is probable that other workers have thought of and used them independently; and, in fact, when recently I was discussing an *Rh* problem with Dr. M. Bessis of Paris, we found that we had both for some time been using this system in working out *Rh* problems.

The phenotype formula is derived as follows: considering first the *C* locus of Fisher, if a specimen of blood has been tested with anti-*C* alone and the result is positive, a single *C* is written. If the result is negative, *cc* is written, whether or not the blood has been tested with anti-*c*, since a negative result with anti-*C* indicates the presence of two *c* genes. If the blood has been tested with anti-*C* and anti-*c* and both give positive results, *Cc* is written. If the result with anti-*c* is negative, *CC* is written, and this can be done even in the absence of a test with anti-*C*. The *D* and *E* systems are treated similarly. But if both the antisera required for one particular system (for example, *Ee*) are unavailable, the statement of the results (for example, *Ccdd*) makes this quite clear. To take a concrete example, let it be supposed that blood of the genotype *CDe/cde* is being tested with the commonest four antisera, namely, anti-*C*, anti-*c*, anti-*D* and anti-*E*, the results will, in that order, be + + + − and the phenotype will be written *CcDee*. The only available information which is missing from this expression of the results is as to whether the blood has been tested with anti-*e*; but the negative result with anti-*E*, in fact, makes such knowledge irrelevant. The absence of a second *D* symbol (*D* or *d*) shows that no test has been done with anti-*d*.

The above suggestions only relate to the common antigens *C*, *D*, *E*, *c*, *d*, and *e*, in respect of which all the suggested conventions appear self-evident. In order to deal with the rarer alleles such as *Cw*, it would be necessary deliberately to adopt certain further conventions by agreement between the workers concerned.

Triassic Plant Remains from the Salt Range in the Punjab

DR. SITHOLEY[1] has described some "bivalved structures" from the Triassic of the Salt Range in the Punjab, which he says "are remarkably like the alga *Cosmarium*"; but he admits that "the latter is far too small to be compared with them". He then compares these structures to Arnold's Greenland organism "undergoing fission". From his description and the photographs, however, I was inclined to think that these structures could best be compared with some two-winged spores, with which they agree both as regards their size and their shape and general appearance.

With the view of confirming my doubts, I examined some of Dr. Sitholey's beautifully coloured specimens which he was kind enough to show me, and I am now convinced that this so-called "most intriguing type" should be referred to *Pityosporites* Seward, a spore form which was fairly common in the Lower and the Upper Gondwana floras[2]. Similarly, the "disc-like bodies" (Sitholey, *loc. cit.*, p. 322, and photos 58–60) found in "fairly large numbers" are, I believe, one-winged spores with a central body and a peripheral bladdery wing forming the "thick wing" (due to the formation of a cast of the air cavity). Similar one-winged spores are one of the commonest types in the Lower Gondwana beds[3]. Dr. Sitholey, while mentioning that these might be "some kind of spores", adds that "there is no real proof of their organic nature"; but it might be said that the proof is as good for these as it is for the other types which have been referred by him to the spore genera *Triletes* and *Sporites*.

It seems that the conditions of fossilization, at this spot, were very suitable for the formation of casts, and they have been formed even in the case of such minute structures. The occurrence of almost identical two-winged, one-winged and other spores (*Triletes*, *Sporites*, etc.) in the immediately preceding Lower Gondwana beds not only confirms the above conclusions but also might perhaps indicate some relationship between these two floras, a thing which is in accord with the views of Seward and Sahni[4]. The relative frequency of the various types of spores in the two floras has, however, to be determined before this can be said with any certainty.

Formation of Citrate *in vivo* Induced by Fluoroacetate Poisoning

THE intensely toxic action of the rat poison sodium fluoroacetate ($CH_2F.COONa$) upon the central nervous system and heart is of special interest because of the stability of the carbon – fluorine link. Bartlett and Barron[1] have suggested that it competes with acetate ion in intermediary metabolism, and Saunders[2] and colleagues that larger chain compounds of this type must be convertible to $CH_2F.CO$ to show toxicity. Recently Liébecq and Peters[3,4] using centrifuged guinea pig kidney homogenates have found that the oxidation of citrate formed from fumarate is inhibited by fluoroacetate. They have proposed the further hypothesis that this poison is metabolized like acetate and enters the tricarboxylic cycle, eventually 'jamming' this and causing accumulation of citrate.

We have now obtained further evidence for this hypothesis *in vivo*; rats injected with sodium fluoroacetate show relatively large accumulations of citrate in heart, kidney and brain tissue.

	Citric acid (γ)/gm. fresh tissue	
	Normal	Poisoned
Heart	(10) 0–58	(7) 558–810
Kidney	(8) 0–48	(8) 854–1220
Brain	(7) 0–46	(7) 118–271

Figures in brackets indicate the number of animals tested. Dose Na–FAc = 5 mgm./kgm. body-weight intraperitoneally; animals killed 1 hour after the injection. The method of Pucher *et al.*[5] was used for citrate estimation, after boiling with acid; 'alkali heating' did not destroy the substance estimated (see Breusch and Tulus[6]).

This is interesting support both for the hypothesis proposed and also for the existence of a tricarboxylic acid cycle as a metabolic path *in vivo*.

We are grateful to Dr. B. C. Saunders for the fluoroacetate used.

Influence of Aneurin and Aneurin Pyrophosphate on Anaerobic Pyruvate Metabolism of Pig Heart Muscle *in vitro*

IN the course of investigations on the anaerobic metabolism of pyruvate by minced pig heart muscle we made some observations on effects of aneurin and aneurin pyrophosphate, which we think worth recording in this preliminary note. We will discuss only the influence of both compounds on carbon dioxide production, and postpone the description of effects observed on the formation of other metabolic products such as lactic acid, acetoin, etc.

The carbon dioxide production of Latapie-mince of the muscle of the left ventricle, suspended in phosphate buffer, *p*H 6·2, containing manganese ions was measured in the Warburg apparatus at 38° C. Each vessel contained 330 mgm. of tissue; 2 mgm. sodium pyruvate was tipped in from the side-bulb. The mince was examined when fresh and also after having been stored during varying times at + 1° C.

Without added pyruvate, the carbon dioxide production was of the order of 10 mm.³ in three or four hours; it was not influenced by adding aneurin pyrophosphate or aneurin.

The accompanying tables show the results of a few representative examples of the numerous experiments, which gave similar results without exception. The accuracy of all our measurements is similar to that shown in Table 2, in which duplicates and riplicates have been recorded.

Table 1

Heart	Condition of tissue	mm.³ CO_2 in 180 min.		% increase of CO_2 prod.
		no APP* added	5γ APP added	
A	fresh	170	186	10
	stored 24 hr.	157	200	28
	stored 48 hr.	110	151	40
B	fresh	208	214	3
	stored 48 hr.	143	192	40

* APP = aneurin pyrophosphate.

Table 1 demonstrates the effect of aneurin pyrophosphate. With fresh mince the effect is very small. It increases with increasing time of storage of the mince at + 1° C. Obviously during storage the aneurin pyrophosphate is split off from one or more enzymes associated with carbon dioxide production n anaerobiosis. The enzyme(s) can be formed again from added aneurin pyrophosphate and the bearer(s) still present. The liberated aneurin pyrophosphate will have been decomposed by the tissue phosphatase. We were able to establish that the aneurin pyrophosphate content of the tissue diminished during storage at + 1° C. We believe the most important result of these experiments is the method it indicates for reversibly removing part of the aneurin pyrophosphate from some bearer(s) in the tissue.

Storage at other values of *p*H or temperature gave much less satisfactory results.

Table 2

		mm.³ CO_2 in 240 min.			
		Heart *C* (fresh)		Heart *D* (fresh)	
I	no aneurin no APP	205, 211	*208*	188, 198	*193*
II	6γ aneurin no APP	202, 205	*203*	194, 192, 193	*193*
III	no aneurin 5γ APP	214, 215, 217	*215*	209, 206, 205	*207*
IV	6γ aneurin 5γ APP	236, 240, 241	*239*	222, 221, 217	*220*
% increase (IV–III)			*11*		*7*

Table 2 concerns the effect of aneurin. This is only seen with fresh mince in the presence of added aneurin pyrophosphate. The aneurin cannot be replaced by equivalent or greater amounts of aneurin pyrophosphate. Possibly this effect indicates the formation of some unknown prosthetic group, which might be a dinucleotide, consisting of aneurin pyrophosphate and aneurin. It is not possible to ascribe the effect of aneurin to the formation of aneurin pyrophosphate by fresh tissue particles, which are impermeable to the pyrophosphate, as simultaneous addition of the pyrophosphate is necessary in order to detect any aneurin effect. Nor can it be explained by inhibition by aneurin of phosphatase action on aneurin pyrophosphate. This inhibition has provided the explanation of the activation by aneurin of carbon dioxide production by alkaline-washed yeast, magnesium ions and aneurin pyrophosphate[1]; but according to Westenbrink *et al.*[2], rat tissue phosphatases are not inhibited by aneurin, even in very large amounts. We were able to confirm these results for pig heart muscle.

Table 3

Heart	Condition of tissue	mm.³ CO_2 in 180 min.				
		no APP no aneurin	no APP 1000γ aneurin	5γ APP no aneurin	5γ APP 6γ aneurin	5γ APP 1000γ aneurin
E	fresh	164		180	194	180
E	stored 48 hr.	153	132			
F	fresh	161	147	163	183	166
G	stored 72 hr.			201		187
H	72 hr.	92	73			
I	120 hr.	156	126	194		179

Table 3 shows the depressing effect of large amounts of aneurin on carbon dioxide production. This effect is observed with mince stored at + 1° C. as well as with fresh mince. We believe this effect to be due to partial replacement of aneurin pyrophosphate on its bearer(s) by aneurin. It can be reversed by larger amounts of the pyrophosphate.

This work forms part of investigations on the metabolism and physiological action of aneurin being carried out by Prof. H. G. K. Westenbrink and collaborators. Full details will be published elsewhere.

Piezo-electric Coefficients of Ethylene Diamine Tartrate

WE have determined the elastic and piezo-electric coefficients of anhydrous ethylene diamine tartrate by measurements of the resonances of bars, and of square plates, cut at various orientations to the axes of the crystals. To find the piezo-electric coefficients, we have measured the capacitance of each specimen over a range of frequencies differing from the resonance frequency by ½–3 per cent. Although all the coefficients can be deduced from eighteen specimens[1], we have used more than fifty different specimens so as to confirm our results fully.

Our values for the elastic coefficients agree substantially with Mason's[2]; but some of our values for the piezo-electric coefficients differ greatly from his. The following table includes also some results obtained by Jaffe by a statical method[3].

Piezo-electric coefficients × 10^8, C.G.S. E.S.U.

	Mason	Jaffe	New measurements
d_{14}	23·5		− 31·1 ± 0·8
d_{16}	37		− 36·5
d_{21}	34	33·9 ± 3	30·6 ± 0·5
d_{22}	− 20	5·4 ± 1·5	6·6
d_{23}	31	− 36·9 ± 3	− 33·8 ± 0·4
d_{25}	14	− 55·2 ± 6	− 54·3 ± 0·8

Interferometric Determination of the Apparent Thickness of Thin Metallic Films

Khamsavi and Donaldson[1] have described an interferometric method for the measurement of the apparent thicknesses of thin metallic films (200–700 A. in thickness). The method described was essentially that due to Wiener[2], modified to bring in the advantages of the sharp interference fringes obtained when multiple-beam interferometry is used[3]. An opaque reflecting layer is deposited over the edge of the film to be measured, and the step in this layer is measured by using it as one surface of an interferometer, and viewing this in reflexion using either fringes of equal thickness or fringes of equal chromatic order. By combining these thickness measurements with colorimetric determinations of the mass deposited upon a given area, they showed that the density of the film appeared to remain constant and equal to that of the bulk metal (silver) down to quite small thicknesses (122 A.).

As they themselves pointed out, however, this may be argued to be a necessary result, since the films used probably have small-scale discontinuities in their structure[4], and the deposition of an opaque reflecting layer over the film to be measured serves to fill up the interstices in that film until its structure resembles that of the opaque film, and hence its density appears to be that of the bulk metal. Some experiments described here tend to confirm this view.

In these experiments a thin film of silver, A_1 (Fig. 1), was laid down on to a substrate either of silver (previously deposited by evaporation to a thickness of about 1000 A.), or of glass, and over the edge of this, two opaque layers B_1 and B_2 were deposited side by side, one of silver and one of some other metal. If the 'packing-in' effect suggested above takes place, it might be expected that the steps in B_1 and B_2 would not be of the same height. This has, indeed, been found to be the case. Four typical measurements with the layer B_2 consisting of chromium, given in the accompanying table, show the magnitude of this effect.

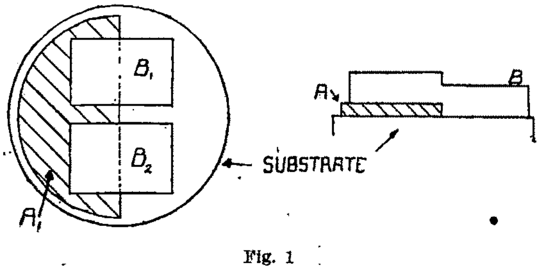

Fig. 1

Substrate	Step in B_1	Step in B_2	b	$\frac{b}{b_1} \times 100$
Silver	247	312	65	26
Silver	470	569	99	21
Glass	202	279	77	38
Glass	377	504	127	34

Typical sets of multiple-beam interference fringes of equal thickness running over the steps in B_1 and B_2 are shown in Fig. 2. Owing to the relatively low reflectivity of the chromium layers, the fringes obtained over B_2 are very broad, and the accuracy o the measurements throughout is not greater tha $\pm$ 25 A.

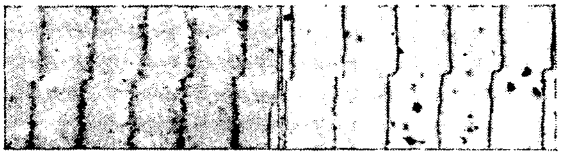

Fig. 2. Fringes with (*a*) chromium; (*b*) silver

These results show that measurements of th thinner film thicknesses obtained by this metho should be treated with caution, since errors of th order of 30 per cent at least may occur, possibl greater. The limitations of the method should there fore be recognized. It should be noted, however, tha the method of Khamsavi and Donaldson, because o the constancy found for the apparent density, afford an accurate means of estimating the mass deposite per unit area in a given film, provided that the laye deposited over the edge of the film is of the same meta as the film itself.

I wish to express my thanks to Prof. S. Tolansky under whose direction this work was carried out and to the Department of Scientific and Industria Research for provision of a maintenance grant.

Absorption Spectra, Molecular Weights, and Visual Purple

HOUSTON[1] has shown that, in the case of absorbin media, the number p of electrons per molecule o solute giving rise to an absorption band with maximum at the wave-length λ_m is given by

$$p = \frac{4\pi n k_m}{s} \cdot \frac{m}{e} \cdot \frac{m_H}{e} \cdot \frac{\lambda' - \lambda_m}{\lambda_m^3}, \quad (1$$

where e and m are the electronic charge and mas respectively, m_H the mass of the hydrogen atom, n th refractive index of the solution at λ_m, k_m the absorption coefficient at λ_m, s the concentration in gram molecules per c.c., and λ' the wave-length at whic the absorption index is half the value k_m. Housto calculated p for some thirty substances, and foun values between 0·1 and 1 in eighteen cases; betwee 1 and 2·7 in four cases; and considerably less tha unity in the remaining cases.

In other words, in the great majority of solution p is about unity or less. This fact offers a new method for the estimation of the molecular weight of substances having an absorption band in the visible o ultra-violet part of the spectrum, for, if we assum $p = 1$, equation (1) becomes on rearrangement

$$M = 0\cdot4343\left(\frac{e}{m}\right)\left(\frac{e}{m_H}\right)\frac{w}{v}\frac{1}{Dn}\cdot\frac{\lambda_m^2}{\lambda' - \lambda_m}, \quad (2)$$

where D is the photometric density, connected with λ_m by

$$D = \log_{10} I_i/I_t = 4\pi \times 0\cdot4343\, k_m\, x/\lambda_m.$$

I_i and I_t are the intensities of the incident and ransmitted radiations respectively, x being the thickness of the transmitting layer; v is the volume of he solution; w the mass of the solute.

Houston's calculations of p were made on subtances of relatively low molecular weight. Before applying the transposed formula (2) to visual purple, it is advisable to check it with a substance of known high molecular weight. Reduced hæmoglobin is suitable for this purpose, because it has a single absorption band in the visible part of the spectrum; thus the effect of other bands in the ultra-violet and, possibly, near infra-red, can be neglected. The values[2] ${}_m = 5550$ A., $\lambda' = 5850$ A., $w/v = 0\cdot01$ gm./c.c., $= 1\cdot33$, $D = 8\cdot1$, $x = 1$ cm., $e/m = 1\cdot76 \times 10^7$ E.M.U., $e/m_H = 9\cdot57 \times 10^3$ E.M.U., and $p = 1$ yield $M = 69{,}500$. This excellent agreement with the gure 68,000 obtained by other methods gives condence both in the applicability of the expression (2) o the determination of molecular weights of this rder of magnitude and also in the assumption that p, the number of electrons per molecule responsible or the mechanism of absorption, is approximately nity. It should be stressed that M is proportional o p; that is, if p is assumed to be $\frac{1}{2}$, the value of M as derived from (2) will also be halved.

Considerable interest centres around the other chromoprotein mentioned above, namely, visual urple. Found in the retinal rods of nearly all verterates and a number of invertebrates, this substance is intimately concerned with the physico-physioogical mechanism of scotopic or twilight vision. It as an absorption maximum at 5020 A. in the visible nd another in the ultra-violet part of the spectrum. As in the case of hæmoglobin, this results in a slight symmetry, and λ' is, therefore, chosen on the long-wave-length side of λ_m also in this case. In this manner the possible contribution from the ‘ultra-violet’ chromophore to the extinction is reduced to a minimum. The molecular weight of visual purple was calculated from the best set of data given by Broda, Goodeve and Lythgoe[3]: $\lambda_m = 5020$ A., $\lambda' = 5480$ A., $w/v = 2\cdot53 \times 10^{-3}$ gm./c.c., $n = 1\cdot33$, $D = 1\cdot67$. The molecular weight of visual purple derived in this manner is 45,600. This is to be compared with the value of 270,000 obtained by Hecht and Pickels[4] using the ultra-centrifuge. In this latter determination considerable difficulty was encountered owing to the formation of micelles of high ‘molecular weight’ by the stromalytic and dispersing agent employed in preparing the visual purple solutions.

Using Hecht and Pickels's value for the molecular weight of visual purple, Broda, Goodeve and Lythgoe[3] calculated that the number of chromophores associated with the protein carrier was ten, assuming that the carrier weight R—the molecular weight per chromophore—was 26,500. This calculation also presupposed that the quantum efficiency of the photochemical reaction taking place on exposing visual purple to light is unity[5].

If the new value for the molecular weight, $M = 45{,}600$, be accepted, the number of chromophores associated with the protein carrier is calculated to be $1\cdot7$. There is reason to believe that the above value for M may be somewhat low; Broda, Goodeve and Lythgoe point out that their value for R should, in effect, be slightly lower: on the above basis it can thus be assumed that there are two chromophores in each molecule of visual purple.

Broda and Goodeve[6] determined the absorption spectrum of visual purple at a low temperature (− 73° C.). At this temperature λ_m moves from 5050 to 5150 A., and the curve becomes narrower, λ' being at 5340 A. Although the concentration of the solution is not given, these authors established the identity at room temperature between the absorption spectra of visual purple dissolved in water and in a 3 : 1 mixture of glycerol and water. Moreover, they demonstrated the reversibility of the changes in the absorption spectrum as effected by the change in temperature.

It seems, therefore, justifiable to calculate the ratio of the molecular weight at room temperature to that at − 73° C., and this is found to be $M_R/M_{-73^\circ\,\text{C.}} = 0\cdot422$.

Considering the approximate nature of these calculations and the empirical bases on which they partly rest, a discussion of the significance of this apparent dimerization is unlikely to prove fruitful at present.

I would like to thank Dr. H. J. A. Dartnall of this Unit for valuable discussions, and Dr. J. G. Wootton, British Postgraduate School of Medicine, London, W.12, for kindly supplying me with his data on hæmoglobin.

Knock in Internal Combustion Engines

THE information given in the two letters[1] on the above subject by D. Downs and A. D. Walsh confirm and considerably extend, with improved equipment and procedure, the observations and conclusions to which the authors refer in the paper by Egerton, Smith and Ubbelohde[2]. In that work it was found that nitrogen peroxide appeared to promote knock when the engine was run with hydrogen, and it was, indeed, suggested that the nitrogen oxides, in the circumstances, tended to sensitize the mixture. Lead tetraethyl was not found to suppress the knock. A fixed-compression Delco engine (6·75 : 1) had been used, and it now appears probable that the conditions were such as gave pre-ignition rather than true knock, and that lead tetraethyl has little effect in inhibiting the pre-ignition but prevents the knock. It would be interesting to test whether hydrogen will knock when no nitrogen or organic vapours are present (for example, using an argon atmosphere and a minimum of lubricating oil).

Our more recent experiments in a Gardner $1L2$ compression ignition engine converted to spark ignition confirm that nitrogen peroxide has a strong pro-knock effect when added as a vapour to methane-air mixtures. The pronounced pro-knock effect of hydrogen peroxide vapour on methane was also investigated with the same engine. Definite audible knock could be produced with a molecular concentration of 0·3 per cent of the methane. It was found that the pro-knock effect could be suppressed by lead tetraethyl. Similarly, when running on weak hydrogen–air mixtures in this engine, the knock was suppressed by lead tetraethyl, confirming, therefore, Downs's and Walsh's observations, and also that the knock induced by nitrogen peroxide in such mixtures could be similarly suppressed.

Dehydrochlorination and Insecticidal Action in Chlorinated Hydrocarbons

EARLY in the history of D.D.T., Martin and Wain[1] suggested that easy dehydrochlorination is necessary for insecticidal action in chlorinated hydrocarbons. This generalization has since been extended to benzene hexachloride, to chlorinated indanes and terpenes. A new group of insecticides, introduced by Julius Hyman and Co., of Denver, Colorado, provides an exception to this rule. For example, 'Compound 118', stated to be 1,2,3,4,10,10-hexachloro-1 : 4,5 : 8-diendomethano-1,4,4*a*,5,8,8*a*-hexahydronaphthalene, is stable to alcoholic potash yet is of the same order of insecticidal activity as D.D.T. Fed to caterpillars of *Mamestra brassicæ*, it was toxic at 0·14 ± 0·003 mgm. per 0·5 gm. larva, the toxic dose of D.D.T. being 0·06 ± 0·011 mgm. To adult *Calandra granaria* walking on filter paper impregnated with oil-solutions of the insecticides, the relative magnitude of the median effective doses (D.D.T. : 'Compound 118') was, after 68 hr., 4·5 : 1 ; after 90 hr., 2·5 : 1 ; after 120 hr., 1 : 1 ; and after 140 hr., 0·8 : 1. This difference in speed of action and differences in the reactions of the poisoned insects indicate that the two insecticides are dissimilar in their modes of action.

Persistence of Optical Activity in an Oxidation-Reduction Reaction

TRIS-O,PHENANTHROLINE ruthenium^{II} perchlorate dihydrate[1], $Ru(phenan)_3(ClO_4)_2.2H_2O$, has been resolved through the antimonyl tartarate to give $[\alpha]_D^{20} = +979°$ and $-971°$ and $[\alpha]_{546·1}^{20} = +1869°$ and $-1863°$ for the ion $Ru(phenan)_3^{++}$. Burstall[2] found $[\alpha]_{579·1}^{25} = +860°$ and $-815°$ for the compound $Ru(dipy)_3I_2.2H_2O$. The orange-red active perchlorates in 6 normal sulphuric acid were oxidized with ceric nitrate to yield the optically active blue ion $Ru(phenan)_3^{+++}$, for which $[\alpha]_D^{20} = +311°$ and $-303°$ and $[\alpha]_{546·1}^{20} = +1,246°$ and $-1,256°$. Reduction of the unstable oxidized ion with ferrou sulphate regenerated the ruthenium^{II} complex wit its rotation unchanged. It is evident that both th di- and tri-valent ruthenium complexes have a ver large abnormal rotatory dispersion.

These observations provide a unique demonstratio of the essential similarity of the oxidized and reduce forms of the complexes, as well as of the simplicit of the oxidation-reduction reaction. It is of interes to note that, within an accuracy of about ± 5 mV. the optical forms and the racemate have the sam redox potential.

The ferrous complex ion $Fe(phenan)_3^{++}$ was als isolated in optical forms, but the rotation was los on oxidation due to the lower stability of the oxidize form.

Complete details will be published shortly in th *Journal of the Royal Society of New South Wales.*

A New Synthesis of Cinnoline Derivatives

IN connexion with an investigation on th elaboration of the Coffey[1] synthesis of 1-ketotetra hydrocarbazoles, a study of the action of acidi reagents on a number of 1 : 2-*cyclo*hexadionemonc phenylhydrazones of the type (I) has recently bee undertaken. Although it has not so far prove possible to obtain 1-ketotetrahydrocarbazolenines (I by this means, an interesting synthesis of cinnolin derivatives has come to light.

4 : 6-Dimethyl-1 : 2-*cyclo*hexadione-1-phenylhydrazone (I, $R = Me$) (red prisms from methy alcohol, m.p. 58–9° ; found : C, 73·1 ; H, 7·4 N, 11·9 ; $C_{14}H_{18}ON_2$ requires C, 72·9 ; H, 7·8 N, 12·2 per cent), which has been prepare by application of Coffey's general method (*lo cit.*), is smoothly cyclodehydrated on dissolutio in concentrated sulphuric acid to 2 : 4-dimethy 1 : 2 : 3 : 4-tetrahydrobenzocinnoline (III, $R = Me$ The base (III, $R = Me$) (yellow needles from ligroin m.p. 111° ; found : C, 79·3 ; H, 7·7 ; N, 13·0 $C_{14}H_{16}N_2$ requires C, 79·3 ; H, 7·5 ; N, 13·2 pe cent) may be isolated with ether, in 85 per cent c the theoretical yield, after addition of water an excess alkali to the reaction mixture. 1 : 2-*cyclo* Hexadione-1-phenylhydrazone (I, $R = H$) may likewise be converted to 1 : 2 : 3 : 4-tetrahydrobenzo cinnoline (III, $R = H$) (yellow prisms from ligroin m.p. 98° ; found : C, 78·1 ; H, 6·6 ; N, 15·3 $C_{12}H_{12}N_2$ requires C, 78·3 ; H, 6·5 ; N, 15·2 pe cent), but the yield in this case is only 15 per cen of theory, a large amount of amphoteric materia being produced simultaneously.

In order to widen, if possible, the scope of th new method, the action of sulphuric acid on benzi monophenylhydrazone (IV) was next investigate The use of 98 per cent sulphuric acid led to extensiv decomposition; but, by employing slightly dilute acid (75–80 per cent w./w.), the non-basic 3 : 4 diphenylcinnoline (V) (yellow prisms from ethe m.p. 149–50° ; found : C, 84·9 ; H, 5·0 ; calc. fc $C_{20}H_{14}N_2$, C, 85·1 ; H, 5·0 per cent) may be obtaine

Influence of Solvent Movement on Sedimentation

ENOKSSON[1] has maintained that the major factor which causes the sedimentation constant of a protein to change with concentration is the counterflow of solvent, which is a necessary result of the sedimentation of the protein. He ascribed to the same cause the differences of sedimentation-rate in terms of which two of us[2] have accounted for the boundary anomalies observed in the sedimentation of mixtures. Pedersen[3] has repeated Enoksson's arguments.

We[2] were aware of this effect; but we consider that it can account only for a minor part of the change of sedimentation-rate with concentration, on the following grounds:

(1) The values of φ, the specific sedimentation volume, which have to be assumed are unreasonably large, and, moreover, are inconsistent with each other and with other data. For example, the value of φ obtained by Enoksson from our data[2] on the variation of the sedimentation constant of serum albumin with concentration should be 5·4 ml./gm. (Enoksson, in his Table 1, wrongly quotes a value of 10 ml./gm.); the value obtained for serum albumin from the boundary anomaly in mixtures with lactoglobulin is correctly calculated by Enoksson as about 11 ml./gm.; the maximum value consistent with the sedimentation constant of serum albumin at zero concentration ($4\cdot5 \times 10^{-13}$), by applying Stokes's law, is 1·5 ml./gm.

(2) The sedimentation constant should, on this theory, vary linearly with concentration down to zero concentration, whereas Pedersen[4] has shown that, in the case of lactoglobulin, the variation becomes very small at concentrations less than 1 gm./100 ml., and this finding has been confirmed recently[5]. There is no evidence that lactoglobulin dissociates under these conditions.

(3) The explanation offered does not account for the fact[2] that a protein which sediments through a solution of a less rapidly sedimenting protein (that is, the faster component of a mixture) does so at the same rate as it would do in the same total concentration of itself alone: the counterflow must be less in the former case than in the latter (cf. paragraph 1).

(4) No account is taken of the proximity of the sedimenting particles to each other; they are treated as though each were sedimenting against the counterflow of a uniform medium of infinite extent. The effect of the proximity of neighbouring particles on their viscous movement must be an important one, though it appears that no satisfactory quantitative treatment can be given at the present time.

Enoksson further maintained that the counterflow effect can account for apparent deficiencies of the amount of a sedimenting protein, as computed from the sedimentation diagram. No deficiency is, in fact, found, provided that the solvent which is displaced is in Donnan equilibrium (which will normally be the case) and that the value used for the specific refractive increment of the protein is obtained by measurement against dialysate. Any deficiency is likely to be due to use of a wrong value for the specific refractive increment and to errors affecting the baseline of the sedimentation diagram[6].

Finally, we should point out that our account[2] of the boundary anomaly is independent of any particular assumption about the cause of variation of sedimentation-rate with concentration.

A TECHNIQUE FOR THE CONTROLLED GROWTH OF EXCISED PLANT TISSUE IN LIQUID MEDIA UNDER ASEPTIC CONDITIONS

By Dr. S. M. CAPLIN* and Prof. F. C. STEWARD
Department of Botany, University of Rochester, New York

EXCISED plant tissues are commonly grown on semi-solid rather than liquid media. Immersion of the cultures in liquid media usually reduces the rate of growth (a result presumably of reduced oxygen supply), while an effect on the ability of a culture to organise has been reported[1]. Given an inherent capacity of a tissue to grow, it is apparent that the growth-rate on an agar medium may well be limited by the rate of diffusion of nutrients through the agar. Hence the growth of such cultures may be more rapid on a liquid medium which is continually mixed, provided that access to oxygen is adequate. Growth in liquid media has obvious advantages wherever quantitative experiments on the absorption or nutritive effect of specific solutes is in question. It will be shown that for certain types of culture the liquid medium produces greater and more uniform growth.

DeRopp[2] has described an apparatus using liquid media for growth of excised plant tissues. In this technique the cultures were to be alternately bathed in the nutrient medium, then drained and exposed to air; but no growth-data from the use of this apparatus have been reported. Moreover, the technique appears rather unwieldy and hence is adaptable only to a relatively small number of cultures.

In the University of Rochester other methods have been devised. The method reported here has been found to be most satisfactory and instructive for the growth of excised plant tissue cultures, and is now described because it may be useful to other workers and may find further application in other biological fields.

In brief, the method makes use of a new type of culture tube: the tubes are mounted on disks which are slowly revolved about a horizontal shaft so that each tube is tumbled end over end.

The culture tube (Fig. 1*A*) is made from 'Pyrex' glass tubing sealed and rounded at each end. At the middle of each tube is a side neck through which the transfer of cultures can be made and, when plugged with cotton, through which gas exchange can occur. The culture tubes are mounted near the periphery of a circular disk of plywood so that the long axis of each tube lies along a radius of the disk and the side neck is parallel to the shaft (Fig. 1*B*). Twenty-four tubes (35 mm. in diameter and 125 mm. long) can be fastened to each disk, and many disks may in turn be fastened to a single shaft: for example, eight disks, accommodating 192 tubes, can be mounted on a shaft 40 in. long. The shaft is driven by a motor and is geared to 1 r.p.m. In this Department the entire shaft is mounted in a cabinet in which constant temperature, humidity and light may be maintained. The revolving klinostat equalizes gravitational stimuli and ensures that all the cultures are subjected to the same environmental conditions.

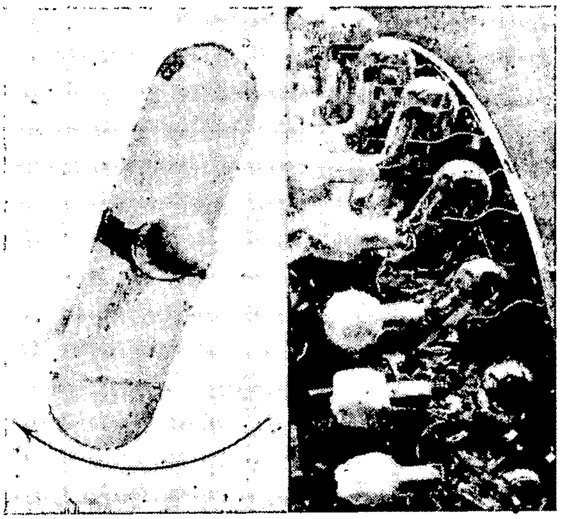

Fig. 1

As a tube 'tumbles' on the rotating klinostat the wet piece of tissue adheres at one end of the tube (Fig. 1*A*), whereas the liquid moves slowly from one end of the tube to the other, and as it does so, gaseous exchange with the outside air is maintained. It will readily be appreciated that with a constant volume of nutrient the fraction of the total time in which the tissue is immersed varies with the proportions of the tube; also with a tube of fixed dimensions the period in air decreases as the volume of nutrient is increased. For any given tube an upper limit to the volume of solution is set when the liquid, flowing along the now horizontal tube, tends to wet the plug. Somewhat larger volumes may be used if the axis of the klinostat is inclined to the horizontal. With these factors in mind, the dimensions of the tube have been fixed as indicated above. Ten ml. of a nutrient medium in a tube is convenient when maximal time in air is desired and also when such factors as the length of growing period for which nutrient must be furnished are taken into account.

In a previous note[3] it was shown that uniform 4-mgm. cylinders cut from carrot root will grow at rates far exceeding those previously described if coconut milk is added to the nutrient agar medium. In the present experiments carrot cultures were grown both in test tubes on agar and in liquid medium on the revolving klinostat described. All the cultures were exposed to the same external conditions and were exposed to the continuous light of a bank of fluorescent lamps. The cultures in the klinostat tubes were grown on a basal nutrient medium[4] to which was added 15 per cent by volume of coconut milk. For the cultures grown in test-tubes 0·8 per cent agar was added to the nutrient medium. All the explants were obtained from carrot cylinders, removed by a cannula, and cut with a multi-bladed cutter into 4-mgm. radial cylinders. Only phlœm cylinders with their inner tangential surface 1 mm. from the cambium were used. This technique and its implications will be described elsewhere.

---

* Postdoctoral Research Fellow, National Institute of Health, Washington, D.C.

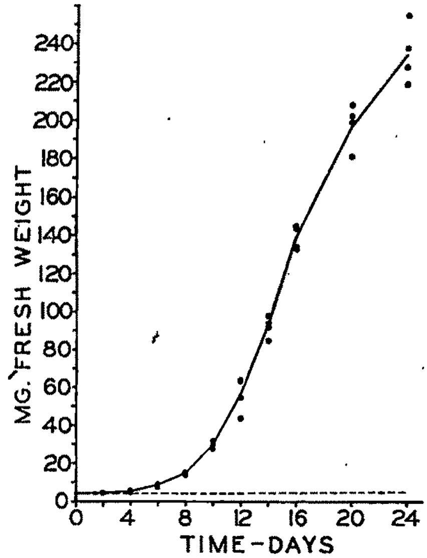

Fig. 2

In a given experiment, cultures grown in the klinostat tubes were not only larger and more uniform but also, under the standardized conditions of the klinostat, the growth-rates of carrot cultures are much more reproducible than when the cultures are grown in nutrient agar in the test tubes.

Fig. 2 shows a growth-curve of cultures of carrot initially 4 mgm. in weight. At each period four replicate cultures were weighed, and the curve is compiled from their means. There is evidently a lag of about four days followed by a very rapid growth reaching a compound-interest rate of increase in twelve days of 34·1 per cent per day. After some days a gradual decrease in the growth-rate occurs. This decrease is probably due in part to depletion of nutrients in the culture medium. (Changing the culture solution after some fourteen days does increase the growth.)

Single cultures readily grow from a 4-mgm. explant to about 175 mgm. before they become so large that they do not readily adhere to the glass, and so fall as the tube rotates. The amount of tissue grown in a given tube and medium may be increased by using more explants per tube, but this markedly reduces the size of each cultured explant. For the most part, the technique has been applied to cultures freshly excised from the carrot root. The rates of growth of subcultures tend to be more variable, probably because they cannot readily be cut into pieces of uniform size and shape which contain identical proportions of active cells.

Cultures grown in liquid media in klinostat tubes and on agar differ in form: the former become compact spheroids, especially when grown in the light, while those on agar become much more succulent and irregularly concave to the medium. In the dark, cultures in klinostat tubes become friable and tend to fall apart. These differences are being investigated and will be reported elsewhere. In the dark, carrot phlœm cultures change from deep orange to pale. In the light they become pale green. Cultures from certain carrots in the light have, however, been observed to become unpredictably coloured with a red pigment in the surface layers of cells. This does not, however, affect the conclusions on the efficacy of the technique here described.

Clearly this technique is applicable to the growth of other materials in liquid media. The growth of *Chlorella vulgaris* in the klinostat tubes was found to compare very favourably with growth under other conditions in liquid media as used by other workers. Ten ml. of the basal culture solution, in equilibrium with the carbon dioxide of the air, inoculated to contain 75 cells per mm.^{3}, produced in 7 days at 25° C. 57,000 cells per mm.^{3} at a light intensity of 240 foot-candles. The technique may well find application in the experimental growth of fungi for antibiotic studies, growth studies of yeast, etc. It has, however, proved its use in quantitative investigations on the growth of plant tissue cultures.

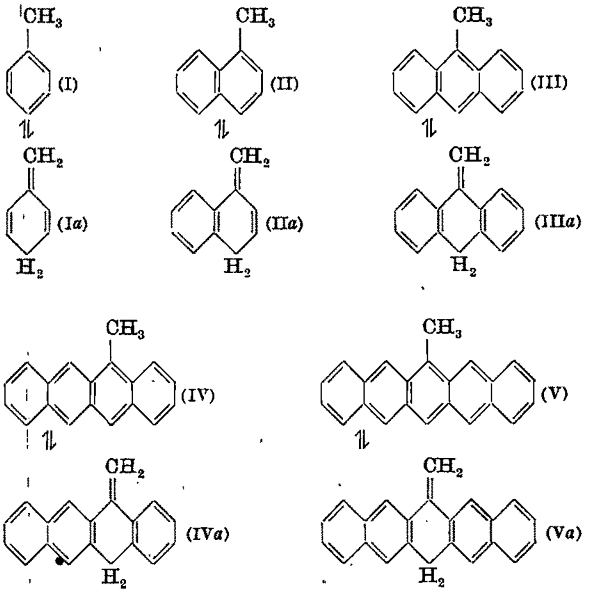
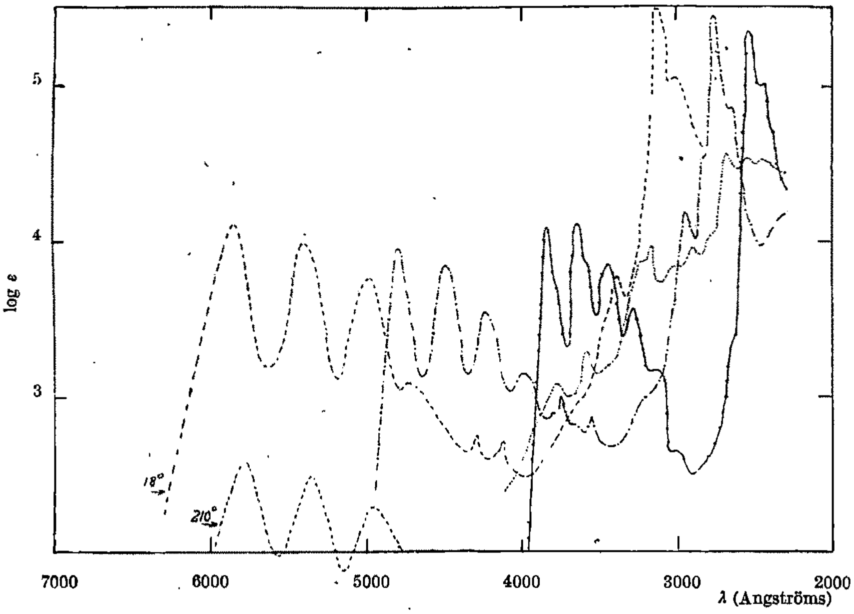
EQUILIBRIUM BETWEEN METHYL-ACENES AND METHYLENE-DIHYDROACENES

By Dr. E. CLAR* and J. W. WRIGHT
Chemistry Department, University of Glasgow

TAUTOMERISM between methyl-acenes (I, II, III, IV, V) and methylene-dihydroacenes (I*a*, II*a*, III*a*, IV*a*, V*a*, respectively) has often been postulated to explain side-chain reactivity of aromatic compounds, but hitherto no methylene-dihydroacene has been isolated. This weakness in the hypothesis has now been removed by the synthesis of pure 6-methylene-6 : 13-dihydropentacene (V*a*). The 'anellation principle'[1] requires a gradual transition in properties in the acene series, and it may be inferred, therefore, that (IV), (III), (II) and (I) will also contain the corresponding methylene forms, but in decreasing proportions.



* I.C.I. Research Fellow.



—•— —•—•—•—•—• Absorption spectrum of 9-methylanthracene in alcohol. Band maxima at: 3850, 3640, 3460, 3290, 3140, 3000; 2540, 2460 A.

—·—·—·—·—·— Absorption spectrum of 5-methyltetracene in alcohol. Band maxima at: 4805, 4490, 4220, 3980; 3750, 3560; 2950, 2755, 2650 A.

— — — — - — — Calculated absorption spectrum of 6-methylpentacene in 1-methylnaphthalene. Band maxima at: 5850, 5410, 5010; 4300, 4120; 3390, 3150 A.

-- — —— — — — (Lower curve.) Observed absorption of methylpentacene at 210° in 1-methylnaphthalene: 5790, 5360, 4960 A. (intensity qualitative); on rapid cooling the fading band maxima shift to: 5850, 5410, 5010 A.

------------------ Absorption spectrum of 6-methylene-6 : 13-dihydropentacene (V*a*) in alcohol. Band maxima: 3770, 3585, 3420; 3175, 3020, 2900; 2690, 2570 A.

This view is supported by study of the absorption spectra of the hydrocarbons (see accompanying graph). The spectrum of 9-methylanthracene (III) resembles very closely that of anthracene, but does not exclude the presence of a small proportion of the methylene form (III*a*), which would have only feeble absorption. The orange 5-methyltetracene (IV) shows an absorption similar to that of tetracene, but the intensity of the bands is considerably lower than in the case of tetracene, whereas with 9-methylanthracene and anthracene the reverse relationship holds. This suggests the presence in (IV) of an appreciable proportion of a weakly absorbing methylene form (IV*a*).

When we come to the pentacene series, we find that the spectrum of the pale yellow methylenedihydropentacene (V*a*) shows no resemblance to that to be expected for methylpentacene (V), which may be calculated by application of the anellation principle[1]. If the pale yellow solution of (V*a*) in 1-methylnaphthalene is heated with exclusion of air to 200°, the solution becomes violet-red and shows the first three bands calculated for methylpentacene (V). The colour fades slowly on cooling.

The fact that methylpentacene exists at room temperature almost entirely in the methylene form (V*a*) is important from the point of view of resonance in aromatic compounds. As each member of the pairs of structures formulated above contains the same number of double bonds as the other member, the energy-difference between the methyl form and the methylene form must consist of the difference in resonance energy. Wave mechanical treatment predicts a decreasing difference in resonance energy of these pairs of hydrocarbons with increasing numbers of rings, until the difference becomes zero with an infinite number of rings[2]. Hence the ratio between methylene and methyl forms should never exceed 1 : 1. This prediction has thus been shown to be entirely erroneous, and the evidence now adduced may perhaps provide a new basis for the calculation of the decreasing energy per ring in the higher acenes.

9-Methylanthracene (III) was prepared as described by Sieglitz and Marx[3]. 5-Methyltetracene (IV) was obtained by dehydration of the crude carbinol formed by interaction of methylmagnesium iodide with tetracenone, prepared by reduction of 5 : 12-tetracenequinone[4] with alkaline sodium hydrosulphite solution. It formed orange-red prisms (from benzene), m.p. 160°, and gave a bright green solution in sulphuric acid (found: C, 94·2; H, 5·7. $C_{19}H_{14}$ requires C, 94·2; H, 5·8 per cent).

6-Methylene-6 : 13-dihydropentacene (V*a*) was similarly prepared from pentacenone[5], and formed pale yellow needles (from xylene), which dissolved in sulphuric acid to give a blue solution which afterwards turned to brown (found: C, 94·4; H, 5·65. $C_{23}H_{16}$ requires C, 94·5; H, 5·5 per cent). The melting point was between 244° and 254°, and in an evacuated capillary the melt was deep red. Oxidation with selenium dioxide in boiling nitrobenzene gave pentacene-5 : 13-quinone. A sparingly soluble by-product from the Grignard condensation formed colourless crystals, m.p. 420° (decomp.), which gave a greenish-yellow solution in sulphuric acid (found: C, 94·2; H, 5·8. $C_{46}H_{32}$ requires C, 94·5; H, 5·5 per cent).

We thank the Department of Scientific and Industrial Research for a grant which enabled one of us (J. W. W.) to participate in the experimental section of this investigation.

USE OF GEIGER COUNTER FOR QUANTITATIVE ESTIMATION OF RADIOACTIVE ISOTOPES IN HISTOLOGICAL SECTIONS

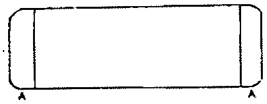
By DR. GEOFFREY H. BOURNE

Department of Histology, London Hospital Medical College

THE problem of obtaining quantitative estimation of radioactive isotopes in histological sections has been under investigation in this laboratory for the past year, and an attempt at its solution is described below.

A detachable, movable stage had soldered to its under-surface a ½-mm. sheet of copper in which a ½- or 1-mm. hole had been drilled. A microscope slide placed in the movable part of the stage could then be altered in position at will so that the whole of any section mounted on it could be 'scanned' by the hole. A lead 'castle' has been designed to take this movable stage and its slide. It consists of a circular shouldered base (5 in. high) which is hollow and contains a brass tube with a screw-on head in which the Geiger–Müller counting-chamber is mounted. The head has a ¾-in. diameter hole by which access is obtained to the window of the counting-chamber. On top of the shoulder fits a square lead tray with an eccentrically placed hole (4 in. diameter), through which the head of the base projects. On top of this tray fit three 1½-in. thick blocks of lead. The movable stage is placed in the tray with the 1-mm. hole in its copper shield directly above the window of the counting-chamber. The three blocks of lead are placed above the tray to reduce cosmic and other interference.

Fig. 4



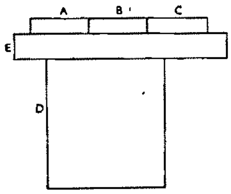


Fig. 1

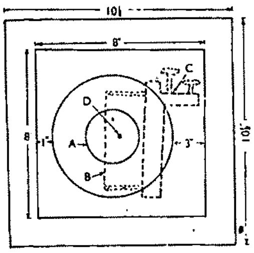
Fig. 3



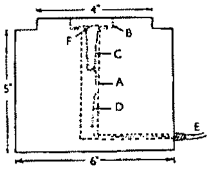


Fig. 2

Fig. 2. Base of lead 'castle'. *A.* Brass tube. *B.* Metal cap holding Geiger–Müller counter in position. *C.* Geiger–Müller counter. *D.* Connexion from Geiger–Müller counter to exterior. *E.* Connexion from castle to power unit and scaler. *F.* Window of Geiger–Müller counter

Fig. 3. Tray for holding movable stage. *A.* Window of Geiger–Müller counter. *B.* ½-mm. copper sheeting underlying microscope slide and attached to movable stage. *C.* Movable stage. *D.* Scanning hole (varying from ½–1 mm.) in *B*

Fig. 4. One of three lead slabs for covering Fig. 3. *A.* Lifting flaps

The advantage of this movable stage is that it can be placed under a microscope and the piece of tissue from which one wishes to count moved directly over the hole in the copper sheet. A photograph can, in fact, be taken of each field of tissue, prior to counting, if desired. Tissues used for this purpose can be cut and mounted in the usual way on glass slides; but if a glass cover slip is used, the radiation from the section is reduced by at least one-half. 'Cellophane' cover-slips are therefore preferable. A 1-mm. scanning hole is about equal to the field seen under a low-power (⅔) objective of the microscope and, of course, covers a piece of tissue of appreciable diameter. Smaller holes can be obtained by piercing ½-mm. sheets of lead with a needle, and by this means holes equal to the size of a high-power (⅙) microscopic field can be obtained. These lead sheets can be stuck over the copper shield with cellulose acetate-tape, the smaller hole being superimposed on the 1-mm. hole in the copper. It is possible to obtain still smaller holes by this method, but it will have to be shown that the apparatus is sensitive enough to make smaller 'scanning' holes desirable.

Dalgaard[1] has also published on this subject, which he has approached in a similar but not identical fashion. He has described a method of obtaining quantitative estimates of alkaline phosphatase activity by allowing the enzyme to deposit radiophosphorus until there is enough activity for counts to be made. It is more difficult to apply this method for estimating activity in histological sections of tissues from animals which have been injected with radioactive isotopes. A few results which give an indication of the scope of the present technique are therefore appended.

A slide bearing a 10-μ section of thyroid but with no thyroid tissue over the scanning hole, and taken from a rat which had been injected with 24 microcuries of iodine-131 six hours before it was killed, was placed in the 'castle'. The background count was 12 per minute. The slide was then moved so that thyroid tissue was over the hole. Sections of about thirty follicles of various sizes could be seen. Ten counts of the same field varied between 26 per minute and 53 per minute, with an average of 39·8.

Pieces of thyroid from the same rat were then treated with hydrochloric acid and the follicles separated away from each other by needles under a dissecting microscope. The tissue was then covered by Apathy's mounting medium and dried. By placing this slide in the apparatus, it was possible to move the scanning hole so that it covered only a single whole follicle. The greater volume of thyroid tissue on this slide gave a higher background count of 71 per minute. Counts from four different follicles of approximately equal size were 143, 123, 153 and 134 counts per minute. It seems that with further refinement we may expect to obtain significant counts at a still lower microscopical level.

The method has also been applied to ground sections of lower jaws and femurs of rats which had been injected with radiophosphorus.

It appears that this technique would be of value for studying the distribution of radioactive isotopes in both adult and particularly embryological tissues.

I am greatly indebted to Mr. R. Oliver, of the Radiotherapy Department, London Hospital, and Mr. A. Love, of the E.R.D. Engineering Co., for most valuable assistance in the design and assembling of apparatus described herein.

---

SPECTROPHOTOMETRIC EQUIPMENT

THE forty-fifth science meeting of the Colour Group of the Physical Society was held on March 30 at the Royal Photographic Society, 16 Prince's Gate, South Kensington, S.W.7, to discuss "Photo-electric Spectrophotometers and Tricolorimeters". The meeting was arranged to explain the difficulties that may be encountered by those contemplating work with these instruments, and to compare the different methods of measurement. Dr. W. S. Stiles was in the chair, and about ninety people were present.

The discussion was opened by Dr. T. Vickerstaff (Imperial Chemical Industries, Ltd.), who had recently been in the United States, and who described American instruments. He said that most research associations there seemed to possess a Hardy recording spectrophotometer and that each owner appears to have done something to improve it. Improvements included those to lengthen the life of the lamp, to overcome difficulties due to polarized light, to reduce scattered light, to improve the efficiency of the sphere-photo-electric cell unit, and to facilitate fitting the paper accurately on the drum. A new design is being made in which a linear wave-length scale is provided both for the visible and near infra-red ranges.

Another widely used and generally approved instrument is the Cary recording spectrophotometer, with an operational wave-length range from 0·21 μ to 0·6 μ and marked ranges from 0·2 μ to 0·35 μ and 0·3 μ to 0·8 μ. The slit widths at which this instrument operates are exceedingly small, about 0·0002 μ. This is a welcomed improvement on the Hardy instrument, in which the sum of the slit widths is 0·02 μ. The Snow-Duplex cathode ray spectrophotometer was seen, but an opinion on its performance was not possible owing to the conditions prevailing at the time. The non-recording Beckman is widely used, and a cheaper model with a direct-reading meter is being marketed.

Three calculators to give C.I.E. chromaticity co-ordinates from the spectral transmission curves were seen. One at the General Aniline Company was coupled directly to the Hardy spectrophotometer and evaluated the summations during the recording. An accuracy of 0·0005 was claimed.

The photo-electric tricolorimeters seen were the Hunter reflectometer and the P.P.G.I.D.L. colour eye. Both these instruments used photo-electric cells with filters to obtain the required C.I.E. distribution curve sensitivity.

General requirements for spectrophotometry were indicated by Mr. H. G. W. Harding (National Physical Laboratory). He said that direct-current light sources are desirable so that sectors can be used. Double monochromators are necessary, and the wave-length control should focus the optical system and alter the slit widths so that a fixed wave-band can be chosen throughout the spectrum. Some of the slits should be curved, and the exit slit should be straight for thermopile work. Some routine measurements require detectors to measure energy ratios of 10^8 to 1, and although it is preferable that the photo-electric cells should act only as out-of-balance detectors, the linearity of their response has to be relied on for such measurements. Reflexion measurements for colorimetry should be made under C.I.E. conditions, and annular cathode photo-electric cells would facilitate this. Completed instruments should be tested separately for wave-length calibration by line sources, and for linearity by neutral glass filters. Automatic instruments that would deal with large specimens are desirable; those now available are very valuable, but they are not as accurate as manually operated instruments, neither will they measure very low transmissions.

Dr. A. Sommer (E.M.I. Research Laboratories) explained how different parts of the spectrum range between 0·2 μ and 1·3 μ can be detected by antimony–cæsium cathodes in quartz or glass envelopes, bismuth–silver–cæsium cathodes and silver–oxygen–cæsium cathodes. Gas-filled cells are unsuitable for precision measurements, he said, and the vacuum types are generally used. Multiplier cells are useful for very low illuminations and for light signals of high frequency. Antimony–cæsium multiplier cells are made with multiplication factors of the order of 10^8. Two types of antimony–cæsium multiplier cell are made in Great Britain, one in which the light passes through the bulb to the cathode on the opposite side (thick-layer type), and another in which the semi-transparent photocathode is deposited directly on the inside of a flat entrance window. The latter type has an improved red sensitivity and reduced blue sensitivity compared with the former, and it has the advantage that a luminous surface can be held within a few millimetres of the cathode. Quartz windows are to be fitted to these cells.

Particular needs for spectrophotometry were outlined by Mr. J. R. Stansfield (Hilger and Watts, Ltd.). He said that hydrogen lamps with a current stability of 1 part in 20,000 give a radiation output constant to better than 0·05 per cent, and tungsten filament lamps can give similar stability, although greater care is necessary in controlling the power supplies. The variations in Nernst filaments and glow-bars for infra-red radiation make double-beam spectrophotometry desirable.

The elimination of stray light should receive particular attention, and although double monochromators are necessary for some work, single monochromators are adequate for many purposes, as some can give a stray light intensity of less than 0·1 per cent of the pure radiation intensity. Double-beam spectrophotometry eliminates errors due to fluctuations in the source of radiation; but as exact equality of two monochromators is difficult to obtain, the practice of passing the two beams alternately through one monochromator is now being adopted. The photo-electric cells of the detectors should, where possible, be used only as indicators of inequalities between successive beams of light. More multiplier cells should be made available, especially ultra-violet sensitive ones, and there is a need for accurate high-speed recorders.

Mr. G. T. Winch (General Electric Co., Ltd.) was unfortunately not able to address the meeting. His contribution was read by Mr. R. G. Horner, and Miss B. M. Young answered questions about it. A description was given of the dispersion and mask method, in which a spectrum is formed and a mask used in the plane of the spectrum to limit the transmission of light of each wave-length. The method is theoretically perfect; but many precautions are necessary if the accuracy of visual methods, namely, 0·01–0·02 in the chromaticity co-ordinates for a 2°-field, or 0·001–0·004 for a 15°-field, are to be obtained without resource to substitution methods. The requirements have been met by temperature control of the photo-electric cell, which is linear to a few parts in 10,000 for a 10 to 1 light ratio, having grid leak values up to 10^{12} ohms in a D.C. amplifier giving a limiting sensitivity of about 10^{-11} lumen to get adequate sensitivity, obtaining a spectral resolution of about 0·0003 μ in a 30-mm. spectrum and by producing masks by the Kodak etch-bleach process. The $\bar{x}$, $\bar{y}$, $\bar{z}$ and spectrum band masks are mounted on a wheel, and a blue temperature-conversion filter is used to compensate for the yellowing of sphere paint when it is part of the instrument.

A general discussion followed, and many aspects of spectrophotometry and colorimetry were considered. At the end of the discussion it seemed that the fully automatic recording spectrophotometers for ultraviolet and visible radiation made in the United States are giving good service, and that the photo-electric colorimeters developed in Great Britain are likely to give the same to colorimetry. It was pointed out that annular cathode photo-electric cells have been made n Britain.

The meeting was closed by a description and demonstration of the new Hilger Uvispek photoelectric spectrophotometer. This manually operated instrument, which covers the wave-length range from 0·21 μ to 1·0 μ, should be of great value in the field of spectrophotometry. H. G. W. Harding

---

AUTOMATIC CONTROL-SYSTEM TERMINOLOGY

At the request of the Ministry of Supply, the British Standards Institution is preparing a "Glossary of Terms used in Automatic Controlling and Regulating Systems". This is divided into four Sections, the second of which, on "Process Control"*, has been published recently; Section 3, which is in preparation, will cover the nomenclature of position control, and Section 4 will deal with automatic regulators; Section 1, which is to contain the terms common to all closed-loop servo systems, will be prepared when the other three have been completed. Every definition is given a four-digit reference number, indicating its section, subsection and position therein.

Section 2 is a welcome publication, representing the first serious attempt which has been made in Great Britain to bring some semblance of order into a field where chaos has reigned supreme. The existing confusion is due partly to historical accident, for the three main divisions of control engineering were developed separately by groups having little contact with each other. For example, the designers of engine-speed governors, of thermostats and of military fire-control equipment failed to appreciate in the early stages that they were all concerned fundamentally with the same problem: namely, that of increasing the accuracy of performance of their equipment, under ever more stringent conditions of load and disturbance, while maintaining an acceptable standard of stability in the system as a whole. It was due to this lack of contact that three separate systems of nomenclature are now current; not only is the same phenomenon referred to by several different names, but also, even worse, the same word is often used by different engineers to indicate quite distinct phenomena.

The aura of mystery which surrounds the whole subject of automatic control in the minds of many engineers can be attributed largely to its illogical and unscientific terminology. In fact, the situation is even more chaotic than that stated above, for there is a considerable variety of usage even among the workers in a single field; a most valuable purpose will be served by the new glossary if it does no more than standardize the practice within each of the three separate fields, and it is to be hoped, therefore, that every control engineer will adhere to the recommended usage.

The glossary could be of more fundamental importance if it also helped to introduce a greater degree of uniformity between the separate fields of control. It is difficult, with only one part now available, to judge to what extent it will do this; but the task is undoubtedly a difficult one, for the technical differences between the fields are in some respects considerable, though by no means as great as is generally believed. It is regrettable, perhaps, from this point of view that it has been found necessary to separate the glossary into sections, for this will tend to emphasize a distinction which is in many instances more apparent than real.

As an example, consider the word 'offset' (definition 2203); in position control practice this is called the 'steady state error'. Is the latter term to be scrapped, or are we to have two names for the same thing? Again, is it impossible to persuade process control engineers to use the terms 'input', 'output' and 'error', in place of 'desired value', 'controlled condition' and 'deviation'? The former sound scientific, the latter sound amateur. The sign of the deviation is defined differently from what is customary for *position* control in Great Britain and in the United States. The Americans are unlikely to alter their practice, so that this will perpetuate the present ridiculous anomaly of having two contradictory definitions in use simultaneously; for it is a sad fact that the only books on control engineering come at present from the United States.

The intention is to review the present standard in a year, and suggestions for improvement are requested. The following comments may therefore be of some value. Terms for 'input element' and 'difference element' are not defined; they might be combined to form an 'input unit'. 'Measuring unit' (2106) is defined in terms of 'measuring element', which is listed among those terms the use of which is deprecated; this emphasizes the point that it is, in fact, necessary. 'Floating control' is not mentioned as a synonym for 'integral action'; it should at least be given, if only to deprecate this common usage. 'Proportional band' (2502) has another meaning, different from that given, namely, "the range within which controller action is linearly related to deviation"; if its use in this sense is deprecated, some alternative should be provided. Finally, the term 'two-step action' (2408) is an unsatisfactory alternative to 'two-position action' (deprecated), since such a control has only one step, though it has two positions.

It would, of course, be possible to make other minor criticisms; but these do not detract from the entirely admirable intention behind this glossary and the treatment which, so far as one can judge at present, maintains the high traditions of the British Standards Institution. R. H. Macmillan

GENETICS OF DIŒCY AND MONŒCY IN *ECBALLIUM*

DIŒCY, the separation of the sexes on to different diploid individuals, occurs irregularly throughout the higher plants. It must therefore have arisen a number of times during the evolution of this group. Thus the genetical control of diœcy is of considerable interest, particularly in regard to the differences between diœcious forms and their monœcious or hermaphroditic relatives. Little information has been available about such differences in the past; but two mimeographed papers[1,2] have now been circulated, in which Dr. F. Galán, of the University of Salamanca, describes the results of crosses between diœcious and monœcious forms of the cucurbitous plant *Ecballium elaterium*.

The monœcious form occurs in the northern half of Spain and the diœcious form in the southern half. The two appear to be readily crossed in both directions. The hybrids are fertile and various F_2 and back-cross progenies were raised. These indicated that monœcy is determined by a third allelomorph at the locus, the other two allelomorphs of which operate the normal sex mechanism in the diœcious form. Thus the monœcious form is (in Galán's notation) $a^+ a^+$, while in the diœcious types males and females are $a^D a^d$ and $a^d a^d$ respectively. The allelomorph a^+ seems to be recessive to a^D but dominant to a^d.

A few plants occur which are unexpected in this scheme. It seems that they are individuals which should be monœcious, carrying both types of flower; but actually bear flowers of only one sexual type. The experiments could not easily have revealed whether there occurred opposite types of aberration, genetically male or female plants bearing both sexual types of flower. No information is therefore available on this point.

About 1 per cent of the plants which presumably are genetically monœcious in Galán's scheme appear as females in the F_1. These must, however, be $a^+ a^d$, so that we may suppose the dominance of a^+ over a^d not to be unconditional. In F_2 and back-crosses, aberrant types appear which cannot be explained so simply. Thus monœcious F_1 plants, which must be $a^+ a^d$, give occasional males, as well as the monœcious and female plants expected, on selfing. We must suppose these males to be genetically $a^+ a^+$ or, less likely perhaps, $a^+ a^d$. In back-crosses, plants which must be $a^+ a^+$ sometimes appear as females. The frequencies of these aberrant phenotypes are about ½ per cent in the back-crosses and nearly 7 per cent in F_2.

The author records that a plant which appears as male or female in its first year of flowering may carry both types of flower in later years, the chance of this occurring being itself genetically controlled. The F_1 was classified as second-year plants, but the F_2 as firsts. Thus the frequencies of aberrant phenotypes in these latter generations may be somewhat overestimated. This over-estimation is, however, unlikely to be great, as only ½ per cent of the back-cross plants seem to be aberrant.

It would thus appear that in addition to their allelomorphs at the main, *a*, locus, the two forms differ in their genetic backgrounds. The diœcious form contains genes, doubtless members of a polygenic system, which, when introduced by crossing into a plant monœcious in respect of the *a* locus, upset its development so that it digresses towards one sex or the other. It is not clear whether the background genotype of the F_1 would ever cause such an upset in $a^+ a^+$ plants; but it does seem clear that, even if it did, the upset would be rarer than is observed in F_2. In other words, the F_1 is heterozygous for the differences in genetic background, and these differences segregate in F_2. Some 7 per cent of the segregant backgrounds are unbalanced in the sense that they divert the normal monœcious development. The disturbing effect of segregation should be less in back-crosses, as indeed the lower frequency of aberration shows it to be.

Thus the evolutionary divergence of the monœcious and diœcious forms seems to have followed the genetic pattern familiar to us from other mechanisms controlling the breeding system. A difference has developed at a main locus, the segregation of which operates the diœcious system. But at the same time the genetic background of each form has been adjusted, in its own special way, to give just those types which the main gene immediately determines. On this basis we can further see how populations could show a gradual transition between monœcy and diœcy through a state consisting of a mixture of the two. It is to be hoped that the author will continue his experiments and establish the genetical interpretation more firmly by further investigation of aberrant individuals and mixed populations in later generations of selected lines.

Dr. Galán has also published an extensive review[3] of the various genetical theories of sex determination in animals and plants; but this is written in Spanish.

SOIL CONSERVATION IN BRITISH COLONIES

THE serious nature of the problem of soil erosion in many parts of the British Colonial Empire has been realized for some time, and in recent years much has been done to extend conservation measures. Considerable experience has accumulated since the position was last reviewed in 1944; but the more recent information has remained scattered, and in 1946, with the approval of the Secretary of State for the Colonies, a questionnaire was sent to the directors of agriculture in dependencies where soil conservation had made good progress. The information received, supplemented by data from published papers and reports, has been collected together by Sir Harold A. Tempany and issued by the Commonwealth Bureau of Soil Science, Harpenden, as Technical Communication No. 45, "The Practice of Soil Conservation in the British Colonial Empire" (Aberystwyth: Commonwealth Agricultural Bureaux, 1949. 10*s*.).

Factors affecting the incidence of erosion and its occurrence under different types of cultivation are discussed, and various forms of soil conservation described. Two main methods are recognized, one dependent on the use of earth structure, the other based on the use of cultural practices and living plant material. It is emphasized that soil conservation should not be regarded as a separate end, but rather ntegrated into systems of husbandry capable of maintaining and enhancing fertility. Besides discussing the problem from the agricultural point of view, attention is also directed to the dangers of erosion around buildings, during construction of roads and in mining areas.

In order that measures for soil conservation shall be fully effective, communal action is called for, which may involve drastic modification in land utilization and agricultural practices. Some kind of legislation is therefore necessary. At present, the provisions for this vary widely in the different dependencies. In some it is built on the American model, whereas in others it is of a simpler form, or even based on the local rules of tribal or native authorities. A number of these provisions are described, those in operation in America being included for comparison.

CARE OF FISH IN TRAWLERS

THE importance of fish, a home-produced protein food, cannot be overstressed. To ensure that such a valuable but highly perishable food reaches the consumer as fresh and palatable as possible, care must be taken in its treatment on board the fishing vessel as well as after landing.

A new edition of "Food Investigation Leaflet No. 3, The Care of the Trawler's Fish" has recently been published for the Department of Scientific and Industrial Research by H.M. Stationery Office, price 4*d*. It is intended to help owners, skippers, mates and crews of trawlers and other vessels that catch 'white' fish to land their catches in the best possible condition. The leaflet, which has been revised and considerably extended, is concerned with the general practice of stowage in crushed ice.

The first section explains broadly and simply the scientific basis upon which the practical recommendations rest. Sea-water bacteria are the main agents of spoilage, bringing about the more striking undesirable changes in odour, flavour and appearance. These bacteria, simple types and harmless to man, are present in very considerable numbers on the outer surfaces, including the gills, of the gutted and washed, freshly caught fish, but not in the flesh. At ordinary temperatures, however, these bacteria multiply rapidly and invade the flesh, producing substances responsible for the stale, and later the putrid, odours and flavours associated with spoiling and spoiled fish, while the external surfaces become covered with dirty-coloured slime and lose their fresh bloom.

Practical recommendations are discussed in the second section. Chilling by stowage in crushed ice, although greatly retarding the activity of the bacteria, and hence spoilage, of the fish, does not stop it. Nevertheless, chilling is the most effective single factor in keeping fish fresh, and the greatest possible care should be taken to see that enough ice is used to chill the fish thoroughly and to keep it chilled until landing. In addition to controlling temperature, it is highly important to gut and wash the fish properly and to handle and stow it with care as soon as possible after catching, avoiding bruising, tearing or crushing. These principles hold good for all voyages, whether of a few days or of three weeks or even longer, as is now customary in the case of the distant-water vessels which provide more than half the fish supplies of Britain. The more fully they are observed, the better will be the general quality and acceptability of the fish.

A new feature of the leaflet is three appendixes. The first outlines the more important characteristics in the odour, appearance, texture, etc., of fresh and spoiled 'white' fish in both raw and cooked states. The second shows diagrammatically how, during stowage in ice for periods up to three weeks, the changing condition of the fish, as normally observed by the senses, is accompanied by increase in bacterial infection and in undesirable chemical changes in the flesh of the fish. The third appendix is a specimen short code of practice that might, it is suggested, be kept continuously before all concerned with the care of the fish.

The preservation of pelagic fish—namely, herring, pilchards and mackerel—is not dealt with in the pamphlet. So far as herring and pilchard are concerned, the problem of preservation scarcely arises on board, as the normal practice is to land the fish a few hours after they are caught. This, however, does not apply to the chief British mackerel fishery, in which the fish are often preserved on board in crushed ice for several days. In a highly perishable fish such as mackerel, great deterioration often takes place in a very short time. It would therefore seem worth while devoting some effort to devising for these fish, too, better methods of preservation on board and in land transit than are generally practised at present.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, June 13

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting.

Monday, June 13—Tuesday, June 14

INSTITUTION OF GAS ENGINEERS (at the Institution of Civil Engineers, Great George Street, London, S.W.1).—86th Annual General Meeting.

Tuesday, June 14

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Wednesday, June 15

PHYSICAL SOCIETY, COLOUR GROUP (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 4 p.m.—Dr. H. J. Plenderleith: "The History of Artists' Pigments".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.*

Wednesday, June 15—Friday, June 17

INTERNATIONAL GAS UNION (at the Institution of Civil Engineers, Great George Street, London, S.W.1)—Fourth International Gas Conference.

Thursday, June 16

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Discussion on "The Practical Postgraduate Training of Mining Engineers".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. D. R. Hartree, F.R.S.: "Some Unsolved Problems of Numerical Analysis".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Annual General Meeting; Dr. R. V. Talice (Montevideo) will show a film dealing with Chagas' Disease.

Friday, June 17

BIOCHEMICAL SOCIETY (in the Department of Chemistry, The University, Nottingham), at 2 p.m.—Scientific Papers.

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Discussion on "Astronomical Navigation in the Air".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Director of Research in the Department of the Chief Development and Research Officer—The Chief Staff and Welfare Officer (Ref. F/EV.85), London Transport Executive, 55 Broadway, London, S.W.1 (June 17).

Lecturer in Biology—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (June 18).

Teacher in the Science Department, Northampton College of Technology—The Chief Education Officer, County Borough Education Committee, Springfield, Cliftonville, Northampton (June 18).

Assistant Physicist to the Hospital and to the Radiotherapy Department—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, endorsed 'Physicist' (June 18).

Senior Assistant, and a Lecturer with special responsibility, in the Department of Chemistry, and a Lecturer in Mathematics—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (June 18).

Lecturer in Physics, for classes from Intermediate to B.Sc. Special standard—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17 (June 18).

Assistant Lecturer (Grade III) in Geography—The Secretary, The University, Birmingham 3 (June 18).

Physicists and Civil Engineers at a Ministry of Supply Research Establishment in Essex, to study effect of explosives on concrete buildings and structures—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.138/49A (June 25).

Assistant Lecturers (2) in the Department of Organic Chemistry—The Registrar, The University, Liverpool (June 25).

Lecturer or Assistant Lecturer in the Department of Biochemistry—The Registrar, The University, Sheffield (June 25).

Pomologists (2), a Plant Physiologist, a Chemist in Domestic Fruit and Vegetable Preservation Section, a Chemist in Cider Section, a Microbiologist in Cider Section, and a Willow Officer for research and advisory duties, in the Department of Agriculture and Horticulture, Long Ashton—The Secretary and Registrar, The University, Bristol (June 27).

Lecturer in Pathology in the University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (June 30).

Principal of the Polytechnic—The Clerk to the Governing Body, Chelsea Polytechnic, Manresa Road, London, S.W.3 (June 30).

Technician for the Clinical Department of the Medical School—The Dean's Office, School of Medicine, The University, Leeds 2 (June 30).

Demonstrator in Geography—The Secretary, University of Durham, 38 North Bailey, Durham (June 30).

Lecturer in Mathematics in University College, Dundee—The Secretary, The University, St. Andrews (June 30).

Scientific Officers (4) for the Soil Survey of Scotland, a Scientific Officer for studies in Plant Physiology, a Scientific Officer for Radioactive studies, a Scientific Officer in the Department of Soil Fertility, and an Experimental Officer as an Analyst in the Department of Soil Fertility—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (June 30).

University Demonstrators in Agriculture, Soil Science, Agricultural Botany, Agricultural Mycology, Agricultural Entomology, and an Assistant in Research in Agricultural Economics—The Secretary, School of Agriculture, Cambridge (June 30).

Senior Research Officer-Chemist, and a Research Officer-Chemist, in the Paint Industries Research Institute (University of Natal), Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (June 30).

Research Demonstrator in Botany and Zoology—The Registrar, University College, Singleton Park, Swansea (July 2).

Lecturer in Civil Engineering, and an Assistant Lecturer in Mathematics—The Registrar, The University, Leeds 2 (July 9).

Research Soil Chemist—The Secretary and Registrar, University College of North Wales, Bangor (July 9).

Assistant Lecturer or Lecturer in Physics—The Registrar, The University, Leeds 2 (July 9).

Senior Lecturer in Physics, specializing in Nuclear Physics, at Auckland University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Auckland, July 15).

Senior Lecturer in Electrical Engineering (Power and/or Machines) in the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 15).

Lecturers (2) in the Department of Meteorology—The Secretary, Imperial College of Science and Technology, South Kensington, London, S.W.7 (July 15).

Mathematical Assistant (Lecturer or Assistant Lecturer grade) for work in connexion with the Automatic High Speed Computing Machine—The Registrar, The University, Manchester 13 (July 20).

Assistant Lecturers (2) in Engineering—The Registrar, The University, Manchester 13 (July 21).

Lecturer in Forestry—The Secretary, The University, Aberdeen (July 21).

Professor of Botany at the University of the Witwatersrand, Johannesburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 30).

I.C.I. Fellowship for research in Chemistry or Physics (or a related subject), tenable at Durham or Newcastle—The Registrar, University Office, 46 North Bailey, Durham (July 30).

Senior Lecturer in Mechanical Engineering in the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

Technician in the Department of Bacteriology—The Supe intendent, Royal Infirmary, Sheffield 6.

Senior Assistant in Physics—The Principal, Derby Technica College, Normanton Road, Derby.

Extension Lecturer (with a good honours degree and qualifie to teach Natural Science, particularly Biology)—The Secretary, Oxfor University Delegacy for Extra Mural Studies, 7 Wellington Squar Oxford.

Graduate Research Worker in the Electron Microscope Labora tory—The Director, National Institute for Medical Researc Hampstead, London, N.W.3.

Chemist to take charge of research work (at present being carrie out in the Department of Textile Industries, Leeds University)—The Secretary, British Brush Manufacturers' Research Associatio Ltd., 80 Coleman Street, London, E.C.2.

Lecturer in the Department of Physics, and a Senior Assistan in charge of Biology—The Principal, Technical College, Queen Stree South, Huddersfield.

Physicist in the Radiotherapy Centre—The Secretary to th United Leeds Hospitals, General Infirmary, Leeds.

Assistant Lecturer and Demonstrator in Bacteriology—Th Secretary, King's College of Household and Social Science, Campde Hill Road, London, W.8.

Junior Assistant Physicist—The Secretary, Bristol Roy Hospital, Guinea Street, Bristol 1.

Biochemist (non-medical)—The Director of the Pathologic Laboratory, Coventry and Warwickshire Hospital, Coventry.

Assistant Professor of Biochemistry—The Dean of Medicin University of Alberta, Edmonton, Canada.

Research Scholarships (2)—The Principal, Technical Colleg Bradford.

Research Fellowships (2) in Physics—Dr. G. M. Shrum, Hea of the Department of Physics, University of British Columbia, Van couver, B.C., Canada.

Lecturer in Rubber Technology—The Clerk, National Colleg of Rubber Technology, Northern Polytechnic, Holloway Road London, N.7.

THE UNIVERSITY IN MODERN SOCIETY

SIR WALTER MOBERLY has had a life-long experience of British universities and their problems, derived as a tutor at Oxford, as vice-chancellor of a great civic university, and since 1935 as chairman of the University Grants Committee. Among these problems he moves with the ease of long intimacy and deep understanding, and in his recent book* he writes with a charm and persuasiveness that match the penetration and balance of his thought. Sir Walter, indeed, disclaims some of the credit for the book, attributing it in part to a conference of between thirty and forty university teachers of Christian outlook held at Cambridge in September 1946, where discussion centred largely on a series of "University Pamphlets" published by the Student Christian Movement Press (see *Nature*, 159, 392; 1947). If, however, to some extent the book does express the converging thoughts of those and of many other minds, its value is derived none the less largely from the quality of Sir Walter's own thought and the lucidity of his prose. It is an outstanding British contribution to constructive thought about the future of the universities, and should be read by all those who have studied the latest report from the University Grants Committee itself, entitled "University Developments, 1935–1947" (see *Nature*, 163, 154; 1949).

Sir Walter's book is, indeed, a natural complement to that report. With the single exception of the question of numbers, which bears so vitally on the maintenance of standards, Sir Walter probes deeply into all the issues raised in that report and into others less readily discussed in an official report. Broadly, the book is based on the conviction that much that ails universities to-day is closely connected with what is wrong with the whole world, and that the malady is rooted chiefly in the underlying assumptions, largely unconscious, by which their life and work are determined. The older universities, Sir Walter points out, grew up in a world very unlike our own. Their traditional assumptions are, to some extent, outdated and, in practice, discarded; but no agreement can be found on the answer to the questions how far this process should continue and what alternative assumptions should take the place of the old. The debate of the last ten years has revealed discord as well as vagueness concerning the *raison d'être* of universities and the standards to which they should pay allegiance and by which their policies must ultimately be judged.

Thus far Sir Walter would doubtless command general agreement; but he admits frankly that his argument and conclusions will only be thoroughly convincing to those who accept certain assumptions on which that argument is based. He postulates first that we are living in an age of exceptional crisis and that the issue depends chiefly on the human factor—in the last resort on the beliefs and sentiments which really govern the actions of men. These beliefs are in flux, and our society has lost direction.

---

* The Crisis in the University. By Sir Walter Moberly. (Published for the Christian Frontier Council.) Pp. 316. (London: S. C. M. Press, Ltd., 1949.) 15*s*. net.

The clue to reconstruction, he postulates, is to be found within our own tradition, and in that tradition the Christian element is vital, although the whole tradition needs to be purged and enriched.

The ability and willingness of the universities to respond to the challenge of the stupendous intellectual task with which, on these assumptions, our generation is confronted, are Sir Walter's primary concern. With these postulates in mind in successive chapters, he reviews the changing conceptions of the task of a university, and some causes of our present discontent. What he regards as the spurious remedies of scientific humanism and classical humanism are then examined and dismissed as inadequate—the latter, perhaps, a trifle too naïvely. Sir Walter then examines the fundamental questions of the aims and basis of a university, and ranges widely and with penetration over the varied and complex problems involved in academic freedom and integration, the content of studies, corporate life, the place of the university in the world, the task of Christians in a modern university and the role of a theological faculty.

This penetrating analysis thus covers the whole field of the functions and work of the universities. But the fundamental issues are always kept firmly in mind; there is no straying into irrelevancies, although Sir Walter writes with wisdom and discernment on many secondary questions as well as on his main theme. If the question of numbers is eschewed it is deliberate, because the number of students, and even what faculties should be maintained, are of secondary importance to that of determining the prime purpose of a university and what the community should expect to find in the new graduate. With this discernment go a balance of judgment, a persuasiveness and charm and a reasonableness that will commend the book even to those least disposed to accept the author's premises in their entirety.

Summarizing the results of this analysis and argument in a final chapter, Sir Walter suggests that while in technical advances the universities are showing the way, only to a slight extent are they protagonists in the transmutation of values. No accepted ideal has replaced the traditional one of training students for leadership in a stratified society now disappearing and in which we no longer believe. The universities have no agreed criteria by which to assess their policies, organisation, teaching methods and the forms of their communal life; and the crisis in the universities of which Sir Walter writes arises out of the contrast between the need of the time and present academic inhibitions and disabilities.

The accuracy of Sir Walter's diagnosis has since been emphasized in the presidential address of Lord Southway to the Classical Association delivered in Manchester on April 21. Lord Southway directed attention to the dwindling number in recent years of those distinguishing themselves in the Classical Tripos at Cambridge or in the School of Literæ Humaniores at Oxford who have found their way into political life or have attained political eminence. In this respect they are greatly outnumbered by the natural scientists, economists, psychologists, technologists and other kinds of experts. For all its priceless value, a higher classical education appears to b making little direct contribution to the daily busines of the modern world.

What needs to be remembered is that in the la two generations the centres of political power hav shifted, and leadership in Britain is no longer co fined to such fields as the Church, the professions, th Civil Service and the armed forces of the Crown. A the same time, there is little evidence that the classical scholar is entering new fields, such as the trade union movement, in which clear thinking and selfless leadership with the classical qualities o restraint and toleration are no less important than for example, in the Church. The very fact that the universities are not ostensibly providing leaders o the requisite calibre in all the important fields o modern life should impel teachers and administrators to think deeply about the issues to which Sir Walter directs their attention.

Sir Walter will doubtless feel recompensed if his book awakens university teachers and administrators to greater concern about these issues, for even the Christian revival for which he himself looks must comprise, as he recognizes, not only recovery but also an element of discovery. The positive policy he advocates starts with the removal of all inhibition on discussion of the vital questions of the day. The university must be a battle-ground where the real intellectual issues of our time are fought out, and their protagonists are confronted with one another In such wrestlings the university must stimulate the characteristic academic excellencies of precision, comprehensiveness and candour, and the penetration which discerns the principles underlying practical disagreements. Moreover, such debates must be conducted at the level at which our several basic acceptances begin to diverge. This demands the restoration of communications between the isolated mental worlds which different groups have come to inhabit.

Even thus far, Sir Walter will doubtless stimulate much discussion; and to adopt his proposals might well shock the governing bodies of certain universities as Bruce Truscot's books have indicated. But S Walter is emphatic that there is a limit to neutrality. There are issues so fundamental that real neutrality is impossible. Irrespective of internal differences, a university as a whole must stand for such basic academic values as a passion for truth, thoroughness in pursuing it to the bitter end, a delicate precision in analysis, a judicial temper, a willingness to learn from all quarters and an uncompromising insistence on freedom of utterance. There are also other values common to the whole community in which the university is set: for British universities these include recognition of an absolute moral obligation, an ingrained respect for law and order and an unshakable conviction that 'people matter'.

Beyond this, Sir Walter insists that in the university it is necessary constantly to explore and probe su values and to discover how far they are genuine a coherent. "It is the special vocation of the universit to think things out and to trace particular trut back to the principles on which they rest." Wh however, he urges that a university should not be colourless or merely neutral on major issues, but should honestly avow the scheme of values by which he ordering of its life and studies is determined, his ontention that these values can and should be ncreasingly Christian values does not lead him to claim for the Christian in the university more than the role of a creative minority.

This brief summary of Sir Walter's main argument may show the wide field he traverses, although it cannot do adequate justice to the persuasiveness with which it is presented or its lucidity and cogency. The argument also flows into numerous other questions, such as the regional responsibilities of a university, in which he firmly believes, the autonomy of a university and its relation to the State. A word must, however, be said of his treatment of the question of studies in relation to the equipment of a student to choose ends and recognize values so as to live his life more purposefully; this is necessary to show that what Sir Walter advocates is not that the universities should train their students with any particular philosophy of life—even a Christian philosophy—but that the students should be helped to formulate their own, and given the best guidance as to where the most effective help may be found.

Sir Walter's solution to the problem of combining general with occupational education involves breaking down the present isolation of subjects and departments, not only giving more attention to fields in which they overlap but also bringing different disciplines to bear on the same problem. The overloading of curricula must be ruthlessly assailed, and for members of staff a new balance between teaching and research must be found. A healthy insistence on discovery and original thought must not, he insists, be over-stressed to the virtual exclusion of any real intimacy between teachers and pupils, while customary methods of teaching and of testing must be reconsidered.

In discussing the way in which the university could dapt and [illegible] aristocratic tradition inernally [illegible] ouches on the question of electi[illegible] izes even more explicitly han [illegible] s Committee in its report that the [illegible] e, a place for others than those who [illegible] vards or scholarships, and he quotes pertinently from Lord Balfour's experience at Cambridge. Sir Walter shares the belief that A. Liddell Hart proclaimed in a recent broadcast on the Third Programme of the B.B.C.: "The closed shop in any form is the very antithesis of a living university". Liddell Hart went on to suggest that the Free University of Berlin may be worth watching "to see whether the German tradition of learning can be freely reconciled with the American development of the community centre, whether the German belief in an élite can be joined to the American faith in ever-widening opportunities".

Sir Walter has made a contribution to the discussion on the place and future of the university which is important not only in its British setting but also in the wider world context with which the nited Nations Educational, Cultural and Scientific Organisation is already concerned. If he raises many controversial issues, he asks many questions to which answers must assuredly be found, and not least he challenges the complacency with which some popular ideas of the functions of a university and of university practice are accepted. The book is more constructive than Ortega y Gasset's "Mission of the University", which although equally challenging was more limited in scope; and Sir Walter is as uncompromising as is Sir Charles Grant Robertson in his belief that the universities must face the issue of religion if they are to become real laboratories and power-houses of spiritual and moral efficiency.

KINEMATIC RELATIVITY

Kinematic Relativity

A Sequel to "Relativity, Gravitation and World Structure". By E. A. Milne. (International Series of Monographs on Physics.) Pp. vii+238. (Oxford: Clarendon Press; London: Oxford University Press.) 25*s*. net.

THIS book contains a systematized account of the developments in kinematic relativity since the publication in 1935 of the author's "Relativity, Gravitation and World Structure". It is complete in itself, containing a sufficient account of the earlier work to enable it to be read independently.

To express opinions about the merits of kinematic relativity is to risk entering a domain of controversy relatively unfamiliar to the pure mathematician. Yet it is appropriate that the book should be noticed by pure mathematicians, to whom, as the author notes, it may have a greater appeal than to the "hard-headed experimental physicist". I have personally found it very attractive, with its clarity of statement, its careful attention to definitions and its logical development; but it is this same abstract approach that makes the theory unattractive to the empirically minded, and partly accounts, no doubt, for its incomplete popularity. Kinematic relativity has been the object of much criticism, some based apparently upon prejudice and some upon misconceptions of Milne's purpose and point of view; but it has fortunately also received a share of the respectful and dispassionate criticism due to a striking and powerfully argued theory.

Milne maintains that kinematic relativity is self-consistent, and that, being so, it is on a footing similar to that of the various systems of geometry, the acceptance of which bears no relation to their applicability to the external world. That may be so: but it is as a cosmological theory, and not as a mathematical *tour de force*, that it will almost certainly be judged, however great may be its intrinsic merits. Those merits are considerable, for, if the book is nothing else, it is a work of art, with a sense of intellectual adventure running through it.

Kinematic relativity is not concerned with the construction of different sorts of universes suitable for the representation of different phenomena, and so has no counterpart of the various worlds (flat, Schwarzschild, expanding, etc.) of general relativity. It is concerned with the construction of a single universe, idealized in the sense of being 'smoothed out', but possessing the main features of the physical world. It is the single stage upon which the whole physical drama is to be played, and Mach's principle (that the contents of the universe determine its laws) is one of its corner stones.

The book is divided into four parts, dealing respectively with kinematics, dynamics, gravitation and electrodynamics. Much of the first part, which contains an account of the now almost classic theories of time-keeping and equivalence, is undoubtedly of lasting value, whatever the ultimate fate of the theory as a whole, for it makes a notable contribution to our understanding of the meaning of time in physics. From it emerges the basic picture of the kinematic universe, a universe populated homogeneously by equivalent particle-observers possessing a common system of time-keeping, their congruent clocks being capable of agreed regraduations. This idea of obtaining alternative descriptions of the universe by the adoption of different time-scales is of profound interest, and has a significance more fundamental than the changes of time co-ordinates (usually physically undefined) permitted in general relativity. The set of particle-observers (the 'substratum') is the idealized representative in Milne's abstract world of the system of galaxies of the actual universe.

The passage from kinematics to dynamics is claimed, remarkably but not unreasonably, to be the only logical possibility, no appeal being made to empirical physical laws. The rest of the book abounds in striking results and bold assertions, most of them already known to relativists through their earlier publication in research papers. Only brief mention of a few of them can be made here. Milne deduces, for example, that the gravitational γ and Planck's *h* vary with the epoch; he claims to have resolved Hubble's difficulties in interpreting the red-shifts; he assumes no electron spin, his electrons being point-singularities, but deduces for them an effective radius equal to that of the classical electron; and he obtains, perhaps most remarkably of all, an equation for the spiral arm of a nebula, which possesses the unexpected property of turning back on itself after a certain number of convolutions, thereby suggesting a 'trail'. How far his results (assuming them applicable to the actual universe) are susceptible of observational test, I am not competent to say: nor do I feel able to venture opinions about the philosophical implications of his ideas. But I am sure that the work is too well reasoned to be lightly dismissed, and I would recommend it to the serious attention of physicists as well as to mathematicians.

H. S. RUSE

FARM MACHINERY

Machines for the Farm, Ranch and Plantation

By Arthur W. Turner and Elmer J. Johnson. Pp. xvi+793. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 36*s*.

THE authors of this book have set themselves the difficult task of providing information on the host of different machines used in American agriculture. They have made a good start by adopting an intelligent system of classification of the equipment under the six headings of seedbed preparation machines, crop planting machines, crop tillage machines, harvest and harvest handling machines, mechanical power and transportation machines, and general service machines and barn and produce equipment. The chapters are well set out with clear headings to the sections and sub-sections, a wealth of good illustrations and with a useful summary at the end of each; in fact, the plans and foundations are excellent. It is unfortunate that the structure built on those foundations is not nearly so good.

Each machine is dealt with from three aspects—its selection, its operation and servicing, and its reconditioning. The part dealing with selection consists mainly of a description of the different available versions of each machine and of the extra fittings or attachments that go with it. The direct advice that the authors give to anyone faced with the job of choosing a machine is usually confined to a few brief and relatively uninformative sentences. For example, their advice to someone choosing a field cultivator is to "Select a size to match the power and with teeth or sweeps best suited for the purpose used". They do not, however, give the reader any idea of the amount of power that field cultivators need, nor do they describe the performance or applications of the various patterns of teeth or sweeps. The authors have, in fact, dodged one of the major problems facing farmers to-day—that of finding a matching set of equipment made up of units that will work smoothly together, and will allow all the farming operations throughout the year to be carried on with a constant and minimum amount of labour. The advice given on the operation, servicing and reconditioning of farm machinery is more complete. The practical farmer and tractor driver would probably have preferred, in addition to the details of setting and maintenance, more information than is given on the technique of working the various machines in the field, while the farm mechanic might ask for more practical instructions on the overhaul and repair of the machines described.

This book, which at a first glance appears to be so useful to everyone connected with agriculture, is disappointing. It gives a very good picture of the range of farm machinery available in the United States, and will be of more use to students and lecturers than to farmers and mechanics, or to those engaged in research in [illegible] of agricultural engineering.

[illegible] HAWKINS

CHEMICAL ES[illegible] OF WA[illegible]

Aquametry

Application of the Karl Fischer Reagent to Quantitative Analyses involving Water. By John Mitchell, Jr., and Dr. Donald Milton Smith. (Chemical Analysis, a Series of Monographs on Analytical Chemistry and its Applications, Vol. 5.) Pp. xi+444. (New York and London: Interscience Publishers, Inc., 1948.) 48*s*.

IN the whole area of chemical analysis few estimations are more important than that of moisture, and few in the past have received such casual treatment. That a volume of this size and character should be devoted substantially to one chemical method of estimating water is welcome evidence of the growing importance attached nowadays to precision in this field. The pendulum may, indeed have swung a little too far; occasionally in this book
